Taylor, Isaac, 'of Ongar,' born in London in 1759, gained some repute as an engraver, and in 1786 settled at Lavenham, Suffolk. He became the minister of an Independent congregation at Colchester (1796), and at Ongar (1810), where he died, December 11, 1829. He wrote many books for children, as also did his daughters Jane (died 1824), and Ann, Mrs. Gilbert (died 1866), joint authors of *Original Poems*. See the *Memoirs of Ann T.* (1825), edited by her brother; and the *Autobiography of Mrs. Gilbert* (1874).—His son, **Isaac T.**, a writer who may be best described as a Christian philosopher, was born at Lavenham, August 17, 1787. He was trained as an artist and mechanician, and several of his inventions in the latter capacity have been found of permanent value; but he soon abandoned art for literature, and during the long period of fifty years he laboured steadily at this vocation. In 1862 he received a pension of £100, which he enjoyed till his death at Stamford Rivers in Essex, June 28, 1865. T. was a voluminous writer—his chief works being: *Elements of Thought* (1823), *History of the Transmission of Ancient Books to Modern Times* (1827), *The Processes of Historical Proof Exemplified and Explained* (1828), *The Natural History of Enthusiasm* (1829), perhaps his best, certainly his most famous production, *Fanaticism* (1833), *Spiritual Despotism* (1835), *Physical Theory of Another Life* (1836), *Ancient Christianity* (1839-40), *Lyola and Jesuitism* (1849), *Logic of Theology* (1859), *Ultimate Civilisation* (1860), *Spirit of Hebrew Poetry* (1861). T. was an enlightened and acute, though not very original or profound, thinker. His works are written pleasantly and in the very best spirit, for he was quite free from that mixture of ignorance and fanaticism which is too often the characteristic of the school to which he belonged.—The **Rev. Isaac T.**, vicar of Holy Trinity, Twickenham, son of the preceding, was born 3d March 1829. He is author of *Words and Places* (1865), *The Family Pen, Memorials of the T. Family* (1867), and *Etruscan Researches* (1874).

Taylor, Jeremy, 'the modern Chrysostom,' was born at Cambridge, August 15, 1613. He studied as a sizar at Caius College, and took his degree of M.A. in 1633. Shortly after he was admitted to holy orders, and his fine appearance and vivid eloquence soon attracted admiration. He won Laud's favour, and through the influence of that prelate was made a fellow of All Souls' College, Oxford. In 1638 he was appointed rector of Uppingham in Rutlandshire. In the civil war, T., whose intellect was impregnably entrenched in reverence for ecclesiastical antiquity, naturally took the royal side, and so lost all his preferments. For many years he lived in retirement in Wales, busily engaged in writing books. In 1658 he went, on the invitation of the Earl of Conway, to Ireland. Immediately after the Restoration he was made Bishop of Down and Connor, which see, as also that of Dromore, he held till his death at Lisburne, 13th August 1667. T.'s writings may be classified as Practical, Theological, Casuistic, and Devotional. Under the first head we have a *Life of Christ* (1649), which deals with the main incidents of the gospel narrative, and steers clear of theological discussions, *Holy Living* (1650) *and Holy Dying* (1651), and *Sermons* (1651-53). To the second class belong his *Episcopacy Asserted* (1642), a temperate and reasoned defence of the principles of his church, with which may be classed his *Apology for Authorised and Set Forms of Liturgy*, *The Liberty of Prophesying* (1648), a plea for toleration and mutual charity among all Christian sects, *The Doctrine of Repentance, or Unum Necessarium* (1655), a work condemned by his brethren for its arguments as to the nature of sin, and *Dissuasion from Popery* (1647). His chief casuistic work is his *Ductor Dubitantium* (1660), an elaborate and somewhat wearisome discussion of very many points in Christian ethics, while his best devotional work is his *Golden Grove* (1655), so called after the mansion of his Welsh patron and friend, the Earl of Carberry. T.'s writings are distinguished in their best parts by a sweet, rich, and solemn eloquence, an artless grace of style, and a heavenly serenity of spirit. His wealth of illustration is absolutely without limit. Simile after simile springs from his teeming fancy until the primary thought is almost lost amid an Oriental splendour of imagery. Emerson calls him the 'Shakespeare of divines.' If we have regard only to the exuberance of his genius, the phrase is not hyperbolical. His learning was vast and curious, and it is frequently introduced in the happiest and quaintest manner to illustrate the subject under discussion. The study of scholastic philosophy has not been without its bad effects on him. Frigid conceits and far-fetched allusions occasionally mar his writings. Personally T. was a man of a truly Christian disposition and of such a noble charity that he stands out in gracious contrast to most of his contemporaries. His sentiments on toleration (like those of Milton) lift him immeasurably above his age and his party, and entitle him to be held in perpetual honour by all who think it a crime to punish freedom of thought. See T.'s complete works with life by Eden (10 vols. Lond. 1854). There is also a fine essay on T. in *Masters in English Theology* (1877).

Taylor, John, styled by himself 'The King's Majesty's Water-Poet,' was born in Gloucester about 1580. After serving in sixteen voyages, having been with Essex at Cadiz and the Azores, he began to ply as a waterman on the Thames, at the same time keeping a public-house, and soon became known as a humourist and a writer of doggerel verses which he hawked about for sale. He was chiefly distinguished by the performance of several fantastic feats of rowing, which are celebrated in his *Travels in Germanie; or Three Weeks, Three Daies, and Three Hours' Observations and Travel from London to Hamburg* (1617), and *The Praise of Hempseed, with the Voyage of Mr. Roger Bird and the Writer hereof, in a Boat of Brown Paper, from London to Quinborough in Kent* (1623). The most memorable incident in his life, however, was his travelling on foot from London to Edinburgh, 'not carrying any money to or fro, neither begging, borrowing, or asking meat, drink, or lodging.' He set out on the 14th July 1618, and reached Edinburgh on the 13th of August. This journey was believed by Ben Jonson to have been undertaken 'in malice or mockage' of him on account of his similar journey shortly before; yet, meeting him at Leith, Ben presented T. with 'a piece of gold of two-and-twenty shillings to drink his health in England.' T.'s journey is narrated in his *Penniless Pilgrimage, or the Moneyless Perambulation of J. T., alias the King's Majesty's Water-Poet, from London to Edenborough on Foot* (1618). In 1630 T. published *All the Works of J. T., being Sixty and Three in Number*, but before his death in 1654 he had produced 138 separate publications. A complete edition of his works is being published by the Spenser Society (Part I. 1867-68; Part V. 1877-78).

Taylor, John, D.D., born in Lancashire in 1694, was educated at Whitehaven, and obtained his degree from a Scotch university. He acted as pastor for many years to a Norwich Unitarian congregation, but in 1757 became tutor in the academy of Warrington, where he died, March 5, 1761. T. was author of *The Scripture Doctrine of Original Sin* (1738), *The Scripture Doctrine of the Atonement* (1750), a *Hebrew Concordance to the English Bible* (1754), *Scheme of Scripture Divinity* (1762), &c. These writings once excited considerable interest. The somewhat Socinian theology of Robert Burns's youth was confessedly influenced by them.

Taylor, Meadows, an Anglo-Indian author and administrator, was born at Liverpool 25th September 1808, and exchanged the drudgery of a merchant's office for a situation in a so-called mercantile house in Bombay, where he was rescued from becoming 'Baxter's shopboy' through the kindness of a relative, Mr. Newnham, then chief secretary to the local government, who procured him a commission in the Nizam's army. In Hyderabad he set himself to earnest study of the languages, and was for four years (1826-30) in charge of a large district of the Nizam's dominions. After a visit to England (1838-40) he was placed in charge of Shorapore, a small state tributary to the Nizam, and here, as in the district of Nuldroog, to which he was transferred in 1850, he laboured with a zeal, wisdom, and benevolence which made him 'a ministering angel to a population whose last refuge from unbearable tyranny was a migration into British territory.' In the crisis of the Mutiny he was sent to preserve order in Berar, and in 1860 was driven home by failing health. He had risen to the

rank of colonel, and was selected by the Queen herself for a Companionship of the Star of India. After a brief visit in 1875 to the scene of his early labours, he died at Mentone, May 13, 1876. The high opinions entertained by competent judges of his character and capacity have given rise to a regret that freer scope should not have been found for his administrative talents. His literary works comprise the terribly realistic *Confessions of a Thug* (1839, new ed. 1858); *Tippoo Sultaun, a Tale of the Mysore War* (1840); *Cromlechs, Cairns, and other Scytho-Druidical Remains in Sorapur* (1853); *Tara, a Mahratta Tale* (1863); *Ralph Darnell* (1865); a *Manual of the History of India, from the Earliest Period to the Present* (1870); *Seeta* (1873); and *A Noble Queen, a Romance of Indian History* (3 vols. 1878). T.'s novels will always rank high in the literature of scenery and manners. See his manly, interesting *Story of My Life*, edited by his daughter (2 vols. Edinb. 1877).

Tay'lor, Tom, journalist and dramatist, was born at Sunderland in 1817. He was educated at Glasgow University, and at Trinity College, Cambridge, where he gained a Fellowship, and took the third place in the Classical Tripos of 1840. In 1845 he was called to the bar at the Inner Temple, and began to go the Northern Circuit, but soon relinquished the legal profession, and became a leader-writer for the *Morning Chronicle* and *Daily News*, at the same time doing much work as a dramatist. T. was one of the earliest contributors to *Punch*, of which, since the death of Shirley Brooks in 1874, he has been editor. In 1854 he was appointed Secretary of the Board of Health, but has recently retired from this position. T. has written over 100 dramatic pieces, nine-tenths of which, he himself tells us, are perfectly original. Among the most noted of his dramas are *To Parents and Guardians*, *New Men and Old Acres*, *Masks and Faces* (written in collaboration with Mr. Charles Reade), *Two Loves and a Life*, *The King's Rival*, *To Oblige Benson*, *The Blighted Being*, *Still Waters Run Deep*, *Our American Cousin*, *The Overland Route*, *An Unequal Match*, and *The Ticket-of-Leave Man*. His volume of *Historic Dramas* (Lond. 1877) includes *The Fool's Revenge*, *Jeanne D'Arc*, *'Twixt Axe and Crown*, *Lady Clancarty*, *Arkwright's Wife*, *Anne Boleyn*, and *Plot and Passion*. He is also distinguished as an art critic, and has edited *The Autobiography of B. R. Haydon* (Lond. 1852), and *The Life and Times of Sir Joshua Reynolds* (Lond. 1865). See *Dramatists of the Present Day*, by 'Q' (Lond. 1871), and *The Dublin University Magazine* for August 1877.

Tay'lor, Thomas, 'the Platonist,' was born in London, 15th May 1758, and destined for the Dissenting ministry, received three years' schooling at St. Paul's. Poverty forced him to accept a clerkship in Lubbock's Bank, but all his leisure he gave up to study, and published in 1787 the *Hymns of Orpheus*, first of a series of classical, and mainly philosophical, translations. Besides occasional papers, he issued in the years 1780-1834 no fewer than 37 different works, in 63 volumes (one-third of them large quartos). Some, published by patrons, belong by their history to the curiosities or amenities of literature; others, for which he was paid by booksellers, to its calamities. Thus his *Pausanias* (3 vols. 1794) brought him but £18; *Plato* (5 vols. 1804) lay for forty-four years entombed at Arundel Castle; whilst *Aristotle* (9 vols. 1812), whose edition was limited to fifty copies, gained him a pension of £100 from Mr. Meredith, a retired tradesman. This T. enjoyed down to his death at Walworth, his residence for forty years, 1st November 1835.

Taylor, William, 'of Norwich,' born in that city in 1765, was educated at Palgrave by Mrs. Barbauld's husband, and in 1779 entered his father's counting-house. Two visits to the Continent made him familiar with French, Italian, and German, and commerce he soon exchanged for an assiduous study of the last-named literature, which he had the honour of introducing to his countrymen. Translating, at first an amusement, was rendered a necessity by mercantile losses, and during his later years T. was a voluminous contributor to the *Monthly Review*. His principal works were translations of Bürger's *Lenore* (1796) and Lessing's *Nathan der Weise* (1805), *English Synonyms Discriminated* (1813), and *Historic Survey of German Poetry* (3 vols. 1828-30), the last now chiefly known by Carlyle's review. T. died at Norwich in March 1836. His pupil Borrow has sketched him in *Lavengro* (3d ed. 1873), and J. W. Robberds published his *Life and Writings* (2 vols. 1843), containing a correspondence with Southey and Sir Walter Scott.

Tay'lor, Zachary, twelfth President of the United States, son of the colonel of a Virginia regiment in the War of Independence, was born in Orange County, Virginia, 24th September 1784. He received a lieutenancy in the 7th Infantry in 1808, was made captain in 1812, and defended Fort Harrison, on the Wabash, with 50 men against a large force of Indians. Throughout the war of 1812 he was engaged on the western frontier with the Indian allies of the English, and was promoted to the rank of major in 1814. He served as colonel in the Black Hawk War of 1832, and in Florida, boldly following the Seminole Indians into their lair among the swamps, inflicted on them a crushing defeat at Okeechobee (1837), for which he was made brigadier-general. After commanding the army of the S.W., and serving on the Arkansas frontier, he proceeded to occupy Texas in 1845. He advanced to Fort Brown, on the Rio Grande, opposite Matamoras, in March 1846, and declining to retire beyond the Nueces on the request of General Ampudia, he was attacked by the Mexicans, who met at his hands the serious reverses of Palo Alto on May 8, and Resaca de la Palma next day. Matamoras fell without resistance, and here T. rested till September, by which time he had raised his small force to 6625 men. On September 9 he attacked, and after three days' fighting took, Montery, which had a garrison of 10,000 regulars. The plan of invasion was now modified by government, and just as T. was about to resume active operations he was ordered to send the greater part of his force to Vera Cruz, where the command had been given to General Winfield Scott (q. v.). With only 5300 effective troops, including 600 regulars, he was attacked by Santa Anna with an army 21,000 strong. Taking up a strong position, and nerving his band for a last effort of heroism, he rolled back the enormous odds, and gained the victory of Buena Vista, February 22-23, 1847. National enthusiasm was evoked, and the thanks of Congress and a gold medal were awarded the victor. 'Old Rough-and-Ready,' as he was called in the army, was nominated in 1848 for President over Henry Clay, General Scott, and Daniel Webster, and subsequently elected over General Cass, Van Buren, and Adams. This 'ignorant frontier colonel' had scarcely time to show how he would deal with the organisation of the newly-acquired territories, with the slave question, or the admission of California, before he died, after a three days' illness, July 9, 1850. One of his daughters was married to Jefferson Davis, and his son, **Richard T.**, fought with the Confederates at Bull Run, served under Stonewall Jackson in Virginia, and commanded as major-general first to the W. of the Mississippi (1863-64), and then in E. Louisiana. He surrendered May 4, 1865, but his force was the last that remained to the Confederacy.

Tay'lor's The'orem, one of the most important theorems in analysis, first demonstrated by Brook Taylor, and used by Lagrange as the basis of his functional calculus. It gives the means for developing a function of the sum of two variables in ascending powers of one of these variables with coefficients which are derived functions of the other. Thus, take any function $\phi\,(x+y)$, and let $\phi\,(x)$ or simply ϕ be its value when $y=o$, then by T.T.

$$\phi\,(x+y) = \phi + \frac{d\phi}{dx}.\ y. + \frac{d^2\phi}{dx^2}.\ \frac{y}{1.2} + \frac{d^3\phi}{dx^3}\ \frac{y^3}{1.2.3} + \&c.$$

or as Lagrange writes it symbolically—

$$\phi\,(x+y) = \phi x + \phi' xy + \phi'' x \frac{y^2}{1.2} + \phi''' x \frac{y^3}{1.2.3} + \&c.$$

Stirling's or Maclauren's theorem is derived from this by putting $x = o$, when we have—

$$\phi y = (\phi) + (\phi')\,y + (\phi'')\,\frac{y^2}{1.2} + \&c.$$

where (ϕ), (ϕ'), (ϕ''), &c., are what the functions become when the variable is put equal to zero. By this theorem any function may be expanded in ascending powers of the variable. In certain cases one of the functional coefficients becomes infinite for a particular value of x; and for this value of x the function fails to be developable. In such cases T.T. is said to fail. See De Morgan's *Differential and Integral Calculus* for a thorough investigation of the limits and failure of T. T.

Tchad, or **Tsad,** a large Central African lake, situated in 12° 30'-14° 30' N. lat., and 12° 30'-15° 30' E. long. It is roughly triangular in shape, shallow, with low shores bordered

by reeds, and according to Rohlfs is 1150 feet above the sea level. In dry weather its area is about 10,000 square miles, but in the rainy season, when its waters rise from 20 to 30 feet, its area is increased fivefold. The Shari (q. v.) on the S., and the Komádugu Yaobe on the W., are its principal feeders. The water of the lake is quite fresh, and fish, amphibia, and water-fowl abound in it. Lake T. has no permanent outlet, but occasionally discharges by the Bahr-el-Ghazal, a wide channel 300 miles long, which terminates in a great depressed plain, where the water is lost by absorption and evaporation. In the centre of the lake is an archipelago inhabited by a fierce piratical tribe, called the Budduma or Yedina, who are independent of Bornu (q. v.).

Tcherka'si, a town in the government of Kiev, Russia, on the Dnieper, 110 miles S.E. of Kiev. It has 6 Russian, 1 Protestant, and 1 Roman Catholic churches, a synagogue; manufactures beet-root sugar, and trades with France and Germany in wool, linen, spirits, cereals, and cattle. Pop. (1875) 13,914.

Tcherkask' Stàro ('old'), the former capital of the province of the Don Cossacks, S. Russia, on the Don, 12 miles S. of Novo-Tcherkask (q. v.). Standing in marshy ground, it is built on stakes and intersected by canals. Pop. 5000.

Tea is the dried leaf of an evergreen shrub of the natural order *Ternstrœmiaceæ*, for which the Linnæan botanical name of *Thea Chinensis* is generally current, though the genus *Thea* is by recent systematists merged in *Camellia*, and the plant is now called *C. Thea* of Link. It includes *C. Bohea*, the China plant, and *C. Theifera*, the indigenous Assam plant. At one time it was supposed that two Chinese species were grown, of which *T. Bohea* furnished the Black T. and *T. viridis* the Green T. of commerce, but further research has shown that these species cannot be maintained. The T. plant may be described as a glabrous or slightly pubescent shrub with elliptic-oblong, acuminate leaves; flowers solitary, on short 2-3 bracteate stalks, with five rotundate, very obtuse, persistent sepals, and white, obovate, obtuse petals; stamens many with versatile anthers, the inner five free; ovary 3-celled villous; styles 3, glabrous; capsule woody, smooth, splitting at maturity into three valves; seeds large, oily, with a hard, smooth, shining testa. Though the varieties are numerous, it is not at present possible to distinguish them within definite limits. The Assam plant is marked by more acuminate and more membranous leaves, is also stronger in taste, but far more susceptible to drought and frost than the China plant. Whether the T. shrub is indigenous in China and Japan is a doubtful question: so far as can be judged, pending the thorough botanical explorations of these countries, it appears to have been imported thither from Assam and Cachar, and possibly also from Siam and Cochin. The fact has been historically established that the culture of T. existed in China in the 4th c., and in Japan in the 9th c., and from these countries it was exclusively obtained for any other part of the globe until the time of the present generation. The import appears to have reached Europe during the early part of the 17th c., but we do not hear of any substantial arrival in England until 1657, and for a long time the high price kept its use limited to the wealthy class. At the present day it is estimated that half the human race use T. habitually or occasionally.

The discovery of the indigenous plant in the forest country of Upper Assam was made in 1834, and since 1840 its cultivation there has taken very firm root, as also in Cachar, Sikkim, the N.W. Himalaya, and other parts of India. The spread of T. field cultivation in N.W. India is mainly due to the late Dr. W. Jameson, who established Government plantations in Dhera Dhoon, Kumaon, Gurhwal, and Kangra. Since then private individuals and companies have taken part in extending its cultivation in these districts, the Government still, however, continuing to foster its growth, not with a view to immediate pecuniary profit, but simply to encourage so important an article of commerce. In one year they distributed to private planters upwards of 130 tons of seed, and 2,400,000 seedlings. In the Neilgherries also, the introduction of T. culture has proved a success, and there can be no doubt that the cultivation will still spread in India, land ranging over a district exceeding 1000 miles in length being more or less adapted to its growth. The production in Assam is spreading with almost unexampled rapidity. The estimated Indian crop for 1877-78 is 34,000,000 lbs.; and the Assam Tea Co., according to a recently-issued report (June 1878), in the preceding year shipped 2,039,324 lbs., yielding a profit of £46,494, giving a dividend of 25 per cent. to the shareholders. Into Java T. was introduced as an agricultural plant about 1835, into Carolina about 1845, into Brazil in 1860, and its culture in Australia is strongly advocated by such high authority as that of Baron F. von Mueller, Government-Botanist of Melbourne. In 1877 the total imports of the United Kingdom amounted to 187,515,284 lbs. (154,996,561 from China; 30,595,093 from Bengal and Burmah), value £12,480,740.

A damp, warm climate, with rains to the extent of 70 or even 100 inches, well spread over the year, and copious in spring, is above all adapted for T. culture. Rich forest-land in its virgin state is preferable to any other. Wide valleys with gentle slopes or undulations, or slightly-elevated level lands with natural drainage, are more eligible than steep hill-sides. Light loams of a reddish or yellowish colour crumbling throughout, of several feet in depth, with a surface stratum of decomposed forest foliage, is insisted on as the most desirable for the largest and most lasting yields. Low lands with any stagnant humidity are not fit for use until drained. The plants must be kept in vigorous growth by the suppression of weeds, periodical turning of the soil, judicious pruning, and adequate manuring. In India an elevation of 4500 feet down to 2000 feet is best. The number of T. plants per acre varies from 1860 to 2700 according as they are placed 5 feet or 4 feet apart. The yield per acre after the fourth or fifth year is approximately 240 lbs. in India and 320 lbs. in Assam. Picking and manufacture extend from April to October, during which period twenty pickings are calculated upon. Growers in India adopt a less complicated system of manufacture than that practised in China, as detailed by Mr. Fortune in his *Tea Countries of China*. The Indian plan for black T. may be shortly described. The operation of plucking is simply the removal from the bush by the finger and thumb of the young shoots with three or four leaves; the amount of the gathering by a labourer per day depending on the weather, the season of the year, the health of the bushes, and the quality of leaf wanted. The produce, after being weighed, is laid in a cool place, and the following day is spread out thinly on mats in the sun, whereby the leaf becomes sufficiently flaccid for rolling without much breakage. The rolling is slow and laborious handwork, performed on a common deal table, and unless conducted with uniformity, the next process of fermentation will also be irregular. The fermentation is effected by thoroughly shaking up the leaf, throwing it loosely into a heap, and covering closely with mats or carpets—the length of time required depending upon the quality and state of the weather. Then succeeds firing in metal pans at a temperature of 240° or 250°. After a few minutes of this treatment it is brushed out, thrown on a table, and again quickly rolled while hot. The same process of firing and rolling is repeated, and finally the leaf is exposed to the sun, or placed over charcoal fires to dry. Some planters send their tea to market as soon as manufactured; others store it till the close of the T.-making season, and by picking and sifting classify their harvest. The T. is generally packed in strong light chests and half-chests, containing 80 lbs. and 40 lbs. For making green T. the series of operations are somewhat different to the above, the firing being for a longer period and at a higher temperature, and instead of fermentation a little sweating only is permitted. Well-made green T. for bulk is nearly twice as heavy as black.

The youngest and therefore smallest leaves produce the most delicate flavoured T. In ordinary commerce four kinds of black and six of green T. are recognised, but the difference between them consists chiefly in size. In the first, *Congou* forms the bulk of the British import, *Pekoe* and *Souchong* being finer and dearer kinds, and *Bohea* coarser; and in the green the various *Hysons* and *Gunpowder* are most familiar. Hlassa brick T. is pressed in the form of a brick, and is prepared when used with butter and salt. It is preferred to all other teas by the natives of Central Asia and Thibet.

An infusion of T. as a beverage has trifling actual nutritive value, but it increases respiratory action and stimulates greater activity of the brain; its effect upon the nervous system being due to the essential oil and the theine, whilst the 14 per cent. of tannin it contains is an astringent.

Substitutes for T. have been found in a number of plants, some of which contain the same stimulating property, such as Maté (q. v.), Guarana (q. v.), Cola Nut (q. v.), and coffee-leaves. Others have been selected by our early colonists, &c.,

for infusion, and the cognomen T. has in consequence been given to the plants. Thus we have Australian T. for several species of *Leptospermum* and *Melaleuca*, Labrador T. is *Ledum latifolium*, Mountain T. is *Gaultheria procumbens*, New Jersey T. is *Ceanothus Americanus*, New Zealand T. is *Leptospermum scoparium*, Oswego T. is *Monarda didyma*, Botany Bay T. is *Smilax glycyphylla*, and W. Indian T. is *Capraria biflora*.

Teak (*Tectona grandis*), a large deciduous tree of the natural order *Verbenaceæ*, with oval or obovate leaves 12 to 24 inches long by 6 to 12 inches broad, white flowers in terminal erect panicles 1 to 3 feet long, and a sub-globose woolly fruit about the size of a cherry enclosed in the inflated calyx. It is indigenous in both peninsulas of India, in the eastern drier parts of Java, in Sumatra, and in some of the other islands of the Indian Archipelago. Much attention is now given to its cultivation in India, the finest T. plantation in that country being formed in 1844 by Mr. Conolly on the river Bepur, in Malabar, and called after him the Conolly plantation. One of the most valuable qualities of T. timber is, that once seasoned, it does not split, crack, shrink, warp, or alter its shape; but its principal value is its durability. In contact with iron, neither the metal nor the wood suffers—in this respect being far superior to oak. It does not, however, resist the attacks of the 'shipworm' (*Teredo navalis*). The various uses of T. are well known. In India it is prized for construction and shipbuilding beyond any other timber, and into Europe it is imported for railway carriages, for decks of ships, and the backing of ironclads. The leaves serve in its native countries for plates, to wrap up parcels, and for thatching; they also yield a red dye. African T. is also a valuable timber for shipbuilding purposes, &c. It is exported from the west coast of tropical Africa, but the tree which yields it is as yet imperfectly known to botanists.

Teal (*Querquedula*), a genus of swimming birds (*Natatores*), in which the bill is as long as the head, and has a horny tip. The second quill is longer than the others, and the nostrils are oval and placed at the base of the bill. The common T. (*Q. crecca*) is a familiar visitant of Britain in winter, although some specimens may remain in this country throughout the year. The T. is of a brown colour intermingled with a metallic green lustre, the back being mottled with white and black. The female is of a uniform dull brown. The average length is 15 inches. The T. is captured in large numbers by decoys, and T.-shooting is a favourite sport in fens and on swampy moors. The brimaculated T. (*Q. bimaculata*) is a second species, and the summer duck (*Pterocyanea circia*) is nearly related to the T. The mandarin duck (*Aix galericulata*) of China is also known as the Chinese T., the males exhibiting a plumage of the most highly variegated description; and the green-winged T. (*Q. Carolinensis*) and blue-winged T. (*Q. discors*) are two well-known species of N. American distribution.

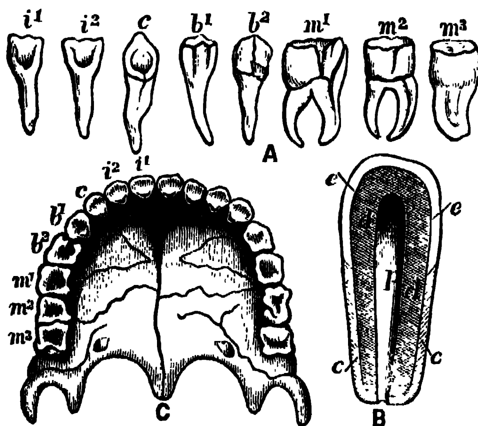
Tea'sel, or **Tea'zel** (*Dipsacus*), the type-genus of *Dipsacaceæ*, consisting of erect, biennial, hairy, or prickly herbs with angular stems; leaves usually connate at the base; flowers numerous in oblong or cylindric heads, with rigid spreading involucral bracts and spinescent exserted floral bracts; corolla lobes 4, short, unequal; stamens 4; style filiform. There are about 17 species distributed through Europe, N. Africa, and W. Asia. Of these the wild T. (*D. sylvestris*) is a frequent plant of the hedgebanks and copses in Britain, growing to a height of from 3 to 4 feet, with stout, prickly, rigid stems, and purplish flowers in heads of from 2 to 3 inches long, with very prominent, stiff, subulate, floral bracts. The fuller's T. (*D. fullonum*) appears to be a cultivated variety of this plant. It may be distinguished by the flower bracts being hooked at the point. The heads form an article of considerable importance to the cloth manufacturer, who uses them, divided into halves and quarters and fixed in a large frame, for passing over the surface of his cloth until the required nap is raised by their strong but flexible hooks. Adequate machinery has not been invented to supersede them in delicacy of operation, and for the required supply the plant is extensively cultivated. In addition to the quantity raised by home farmers, imports are made into England from Europe to the extent of about £5000 annually, representing some twenty millions of T.-heads.

Tech'nical Instruc'tion embraces such branches of education as have a direct relation to the various arts and manufactures. The subject thus covers a very wide area, and includes many different methods and processes of instruction, such as school-training in the theoretical basis of various arts, and an apprenticeship system in which practical manipulation is taught. T. I., however, as understood since the agitation for its extension which arose in Great Britain chiefly after the Paris Exhibition of 1867, applies principally to instruction in those sciences which have a direct bearing on manufacturing industries, and in the principles which underlie mechanical and manipulative trades. The demand for increased attention to such subjects as come under the head of T. I. arise partly out of the fact that various Continental nations had instituted special schools of T. I., on the fostering of which they expend large sums of money to the manifest advantage of their industries, and also from the fact that the modern system of manufactures at once demands greatly increased technical knowledge, while it has rendered the acquisition of such knowledge in the workshop increasingly difficult. Thus the minute subdivision of labour greatly circumscribes the area of the artisan's practical knowledge, and the extensive application of machinery in many instances makes him, so far as his work is concerned, little more intelligent than the machinery itself. The Science and Art Department of the Committee of the Council of Education spends upwards of £300,000 annually on the subjects specified in the article Schools of Design and Art (q. v.), and also on the teaching of science in special schools, on science colleges at South Kensington, London, and in Dublin, on special museums of science and art, including South Kensington Museum, the Geological Museum and School of Mines, London, the Industrial Museums in Dublin and Edinburgh, and on the geological survey of the United Kingdom. Chairs of applied science are now being introduced into the universities, while the chief scientific foundations are Owens College, Manchester, the Newcastle College of Science, and the College of Science at Leeds. More specialised and limited schools, on Continental models, have also been founded in Bradford and Glasgow, devoted to instruction in the art of weaving. The various livery companies and the municipal corporation of London have jointly formed a board of governors of the 'City and Guilds of London Institute for the Advancement of Technical Education,' for which an annual income of £12,000 is already (1879) secured. The Institute is intended as a central technical school, to give assistance to evening classes, trade schools, &c., and to develop the system of technological examinations organised by the Society of Arts. The Commissioners of the Great Exhibition of 1851 have also resolved to realise and devote part of their funds to the foundation of a technical school at South Kensington, London.

Technol'ogy (Gr. *technē*, 'art,' and *logos*, 'a discourse') is a term of modern origin meant to indicate the scientific exposition of the principles upon which raw products and materials are prepared by human industry for commercial purposes. It includes within its scope, 1st. chemical T., embracing the industries which have to do with changing the chemical structure and composition of materials; and, 2d, mechanical T., in which only the form or shape of the substances operated on is altered or modified without affecting its essential composition. Of course, a large number of industries may be ranged partly under one and partly under the other of these heads, but T. is not to be regarded as in itself a science capable of strict systematic classification and limitation.

Tectibranchia'ta, a group of Gasteropodous Mollusca, in which the gills are concealed by the *mantle*. It includes such forms as the sea-hares (*Aplysiadæ*), bubble-shells (*Bullidæ*), &c. The shell is developed both in the larvæ and adults. The T. are contradistinguished from the *Nudibranchiata* (q. v.) or 'naked-gilled' gasteropods.

Te De'um is the name (from the opening words *Te Deum laudamus*) of a well-known hymn which is in almost universal use in the Church. According to the rubric for Matins in the Roman Catholic breviary, T. D. is always said after the last lecture on all Sundays, and on feasts only (except on the feast of Holy Innocents, when it does not fall on a Sunday) from Easter to Advent and from the Nativity to Septuagesima. But during Advent and from Septuagesima to Easter it is said only on feasts; from Easter, however, to Pentecost it is also said in the ferial office, except the second feria of Rogation Days. In the Anglican Church it occurs in the morning service after the first lesson. The authorship of the hymn is uncertain. By an



old tradition it is ascribed to St. Ambrose and St. Augustine jointly, the two having given utterance to their feelings in this inspired song when the latter was baptized by the former (386). Most probably it was composed for the use of the Gallican Church in the 6th c.

Teel-Seed. See SESAMUM.

Tees, a river of England, rises under Cross Fell, in Cumberland, flows E., forming the boundary between the counties of Durham and York, and after a course of 90 miles enters the North Sea 10 miles below Stockton, to which it is navigable for vessels of 60 tons. The scenery of Upper Teesdale is far-famed. At Holwich Force, 4 miles from Middleton, the T. is crossed by Wynch Suspension Bridge. Higher up is High Force, one of the finest falls in the kingdom, where the T. descends 69 feet over a mass of greenstone. The iron shipbuilding on the T. amounted (1878) to 12,587 tons.

Teesta (*Tista*), a large river of N. Bengal, India, which rises in the Thibetan Himalayas, and after breaking through Sikkim in a fine gorge flows S.E. into the Brahmaputra after a total course of 313 miles. It used formerly to flow S.W. into the Ganges, but the main stream was diverted by a great flood in 1785. The T. has a large traffic in rice, jute, and tobacco.

Teeth, the name given generally to hard parts developed in the mouth of animals. T., however, are not to be ranked as parts of the skeleton, although they are somewhat allied to bone in chemical composition, and attached in higher animals to the skeleton itself. On the contrary, they belong to the exoskeleton or outer structures of the body. They are developed from the *dermis*, or under of the two layers of the skin, which layer, in a modified state, forms the gum or lining membrane of the mouth. The history of the *development* of the T. clearly shows the origin and true nature of these structures. Thus in man we find a groove to make its appearance in the jaw of the embryo at about the sixth week of intra-uterine life, this groove being the *primitive dental groove* of Goodsir. In this groove small projections or *papillæ* arise, these being the moulds upon which the T. are formed. The papillæ become thereafter shut off into separate sacs or follicles. The enamel of the tooth is formed by a little cap of the papillæ, whilst the body of the tooth is formed by the papilla itself, the substance of the papilla ultimately becoming the *pulp* of the fully-formed tooth. When the T. are fully advanced in development, they pass through their covering constituted by the gum, and are then said to be 'cut.' Such is the history of the development of the milk-T., or first or temporary set which man is known to possess. The second T. are formed in little sacs or bags which

TEETH OF MAN.

A, The teeth of man, removed from the half-jaw to show their form; i^1 i^2, incisors; c, canine tooth; b^1 b^2, bicuspid or præmolar teeth; m^1 m^2 m^3, molars. B, Section of incisor tooth of man, to show its structure; c c, cement; d d, dentine; e e, enamel; p, pulp-cavity. C, Teeth of human subject, as seen *in situ* in the upper jaw. References as in upper figure.

exist as processes of the sacs or follicles in which the first T. are developed. T. are thus proved to be wholly *dermal* or *skin structures*, and to have no relationship, in so far as their structure or nature is concerned, with the skeleton itself.

Regarding the nature and structure of the T., we may select those of man by way of familiar illustration, and prior to examining the comparative anatomy of the subject. The ordinary structure of a tooth is well illustrated by the diagrammatic section of an incisor or front tooth of man.

The body of the tooth (*a*) is composed of a substance to which the name of 'dentine' or 'ivory' is given; the fang or root is invested by a layer of 'cementum' or 'cement' (*c c*); while the 'crown' is covered by a substance of great hardness termed 'enamel' (*e e*), and which serves on this account to protect the 'crown,' and prevent the too rapid attrition or wear of the tooth. Internally, the pulp-cavity (*p*) of the tooth is seen. It contains a highly-vascular tissue, richly supplied with nerves, and termed the 'dental pulp;' the development, growth, and nourishment of the dental tissues being carried on by means of this structure.

Regarding the form and functions of the T., four varieties are to be distinguished. The first kind comprehends the 'incisor' or 'cutting' T. (A,C,*i*). These are placed in the front of the jaw (C, i^1 i^2), and are characterised by their sharp chisel-like edges. Functionally, the incisors are, as implied by their name, the 'cutters' or 'dividers' of the food, and in the *Rodentia*, exemplified by the hare, beaver, &c., the incisor teeth are greatly developed, and form the organs with which the 'gnawing' operations of these creatures are carried on. The second series of T. are known as the 'canine' or 'eye' T. (A, C, *c*). These are situated next the incisors in each side of the jaw, and derive their name from the fact of their especial development in the *Carnivora*, exemplified by the lion, dog, &c. The 'bicuspid,' 'præmolar,' or 'false molar' T. (b b^2), succeed the 'canines,' and are distinguished by their relatively broader crowns, each 'bicuspid' tooth bearing on its crown two points or cusps, from the possession of which the name is derived. The fangs of the 'bicuspid' T. further exhibit a tendency to become bifurcated, or divided in two. The fourth and last variety of T. is known as the 'molars' or 'grinders' (A, C, m^1 m^2 m^3): these T. having two or even three fangs, and being distinguished by their broad flattened crowns, which adapt them for the particular function of crushing and grinding the food. The molars of the upper jaw in the human subject have four cusps, while those of the lower jaw are provided with five points. The 'deciduous' or milk set of T. are composed of three kinds of T. only; incisors, canines, and præmolars; the true molars being thus unrepresented in the milk set, and making their appearance for the first time in the permanent set.

These various and typical varieties of T., although fully represented in the higher forms, are not necessarily present in their entirety throughout the whole class; on the contrary, we find many and very great modifications in the number and disposition of the T. as we descend the scale; the arrangements varying of necessity with the life and habits of the animal.

The *scientific definition* of teeth is founded upon the position and implantation of these organs in the bones to which they are attached. Thus an upper incisor is a tooth implanted in the premaxilla; an upper canine is the foremost tooth of the maxilla provided it is not at a considerable distance from the front of the bone, in which case it would most likely be a præmolar. A lower canine bites in front of the upper canine, and lower incisors are placed in front of or in a line with the lower canine. Præmolars are T. behind the canines and in front of the molars; but it may be necessary to define præmolars (in the absence of molars) as T. behind canines and having vertical predecessors, or in front of molars which have such predecessors. The *number* of T. in vertebrates varies exceedingly, as do also the situation, succession, and form of these organs. Thus, in man's class, the dolphins may have even 200 T. A species of armadillo possesses 90; and in fishes the T. are so numerous as to defy computation. Some fishes (*e.g.*, hog-fishes) may have but a single tooth in the palate. Ceratodus (q. v.) has but two; while such fishes as the pike, perch, &c., have a very large supply. In man and higher animals generally, T. are confined to the jaw-bones; but in fishes they may be borne by any and every bone which enters into the composition of the mouth. T. are not invariably fixed in *alveoli* or sockets. Only in mammals, indeed, is this mode of implantation exemplified. In fishes the T. as a rule are attached to the bones by ligament or by bony union. The latter is the method

of attachment in *Reptilia* at large. In lizards, the T. are attached by bony union to the top of the jaw-bones. Such lizards are *Acrodonts.* In others the T. are attached to the outer side of the jaw, when the animals are named *Pleurodonts.* T. as a rule grow from pulps which sooner or later become absorbed, so as to arrest the growth of the tooth beyond a certain stage. In some animals (*e.g.*, elephants and rodents), certain of the incisor T. grow from *permanent pulps*, and continue to increase during the whole life of the animal; with the result of producing the well-known 'tusks' or T. which serve for purposes of gnawing. Canine T. become tusk-like through a similar development of these pulps in such animals as walruses and pigs: one of the *Suidæ*—the Babyroussa hog—possessing curious twisted canines in both upper and lower jaws. The Narwhal's (q. v.) long ivory pole is simply a highly-developed tooth. The *succession* of the T. varies equally with their form and number. Man and most mammals have two sets, and are therefore named *diphyodont.* Other mammals (*e.g.*, toothed whales and *Edentates*) have but one set, and are named *monophyodont.* Among lower vertebrates we may find an unending succession of T. to be the peculiar possession of certain forms. In *Crocodilia* the T. succeed each other from below upwards during the entire lifetime of the animal: and in such fishes as the sharks, rays, &c., row after row of T. is developed, to replace those which are lost or worn away.

Diseases of the T.—The T. are liable to various malformations, accidents, and diseases, the more important of which are the following:—

1. *Irregularity of the Permanent T.* may be the consequence of contracted and ill-formed jawbones, or of stomatitis depending upon congenital syphilis. If the canine T. or incisors project, much may be done to remedy the deformity by persevering efforts to push back the tooth by the fingers; but if this should fail, the projecting tooth may be removed, or one of the bicuspids may be extracted to make room for it. When the under incisors come in front of the upper ones, the deformity may sometimes be rectified by pushing the upper teeth forward with the tongue and fingers, or the upper T. may be pressed forward and the lower T. backward by putting the end of a spoon-handle behind the upper incisors and pushing them forward, using the lower incisors as the fulcrum of the lever. The wisdom-T., especially of the lower jaw, are extremely liable to displacement, and may produce ulceration of the cheek or tongue, necessitating extraction.

2. *Fracture and Dislocation of T.*—When a portion of a tooth is broken off without exposing the pulp cavity, the exposed surface should be filed smooth; but if the pulp cavity is exposed, it should be touched with lunar caustic, and an artificial tooth may be afterwards fastened to the stump by a pivot. When a tooth is loosened by a blow, it should be fastened to its neighbours by a ligature; and should it be entirely driven out, it should be replaced and similarly fastened after the bleeding has ceased.

3. *Caries of the T.* generally commences in the dentine immediately below the enamel. The tissue becomes softened, and a cavity is formed extending outwards towards the enamel and inwards towards the central or pulp cavity. The unsupported enamel gives way, and irritant substances, heat, cold, &c., find entrance to the pulp cavity and cause excessive pain. The pulp cavity is attacked by inflammation, suppuration, and ulceration, and the tooth, deprived of its nourishment, decays, nothing being left but the outer coating of enamel, which breaks away by degrees. Caries is a frequent cause of toothache, headache, earache, deafness, photophobia, and occasionally of strabismus. In such cases there may never have been toothache, but the neuralgic symptoms may disappear when the diseased T. are removed. *Treatment.*—If the caries be slight and recent, the decayed portions may be removed by proper instruments and the cavity filled up; but if the decay has advanced far towards the pulp cavity, or has laid that open, it may be necessary to deaden the sensibility of the tooth, so as to enable it to bear the stopping and protect it meanwhile from contact with food or saliva. This may be effected by various means, such as filling the cavity with a bit of cotton wool dipped in a solution of mastic, in eau de Cologne, in alcohol, or in a solution of gutta-percha in chloroform.

4. *Necrosis of the T.* is characterised by blackness of the teeth and looseness of its socket, and may be caused by violence, or by inflammation of the pulp; or, secondarily, by necrosis of the jaw resulting from the poisonous action of phosphorus fumes, or from the specific poison of certain eruptive fevers.

5. *Toothache* is not so much a disease as a symptom of various diseases of the T, and of contiguous parts. Toothache may be caused by inflammation and suppuration around the fang of a tooth, the matter making its way to the surface either along a canal by the side of the fang of the tooth opening at the edge of the gum, or through the gum itself at a point corresponding to the end of the root of the tooth implicated. In its earliest stage the tooth may be extracted, or the gum may be freely lanced and hot poultices applied to the swollen part of the face, and when matter is detected a puncture should be made through the gum. In general, the removal of the tooth is necessary. Toothache may be inflammatory, neuralgic, rheumatic, and gouty. *Inflammatory* toothache depends generally upon caries, and the seat of the inflammation may be in the pulp of the tooth, in the nerve-twig entering the pulp cavity, or in the periosteum investing its roots. The tooth is excessively tender, and the pain is aggravated by pressure, and by hot and cold liquids taken into the mouth; and if the part be much irritated, it is liable to acute inflammation with most agonising toothache. The following treatment has been recommended:—'Let the patient have a dose of calomel and colocynth; confine himself to spoon diet; let him wash out the mouth with a solution of carbonate of soda in water; let the gum around the tooth and between it and its neighbours, if tumid or tender, be deeply scarified with a fine lancet, then let the cavity be filled loosely with a little bit of cotton dipped into a solution of tannin and mastic formed by dissolving a drachm each of tannin and mastic in an ounce and a half of sulphuric ether; and if the toothache is curable at all, this plan, with a little patience, will be almost sure to succeed. If the pain is very violent, half a grain of powdered acetate of morphia may be taken up with the cotton imbued with the tannin, which should be warmed before it is put into the cavity. In some cases a whiff of chloroform will lull the pain. As soon as the pain is relieved, the tooth, if of use, should be stopped, and if of no use it should be extracted.' A drop of strong solution of nitrate of silver, or solution of alum or of tannin, introduced into the cavity of the tooth, may afford relief. *Inflammation* of the central pulp may affect a tooth that is apparently sound, causing severe pain in the tooth extending to the head, and in such cases leeches may be applied to the gums, and purgatives should be administered. *Neuralgic* toothache may occur in T. that are entirely sound or partially carious, and is characterised by paroxysmal pains which come and go suddenly at more or less regular intervals, there being little or no swelling of the gums. It is very common during the earlier months of pregnancy, and often depends upon changes of the weather among those of a neuralgic tendency. The treatment consists in the administration of aperients followed by quinine in large doses. *Rheumatic* and *gouty* toothache is common to persons of the rheumatic and gouty diathesis, and may occur in connection with sound or carious T. In general the pains fly about the jaw, affecting no tooth in particular, and the pain is not relieved by extraction. Muriate of ammonia in half-drachm doses may be given every four hours, and other medicines used in the treatment of rheumatism and gout.

Hæmorrhage after Extraction of T. may be arrested by stuffing the socket with lint saturated with turpentine or perchloride of iron or solution of tannin, and applying a compress of lint or a piece of cork thicker than the bodies of the adjacent T., so that the T. in the opposite jaw may keep up a pressure. See DENTISTRY and DENTITION.

Teff. See MEADOW GRASS.

Tef'sa, or **Tefza**, a town at the foot of the northern face of the Atlas range and on the river Um-er-beg, 135 miles N.E. of the city of Morocco. It is the centre of the fertile district of Tadla, and has manufactures of woollen cloth and shawls. Pop. 10,500.

Teg'nér, Esaias, Sweden's most famous poet, was born at Kyrerud in Värmland, November 13, 1782. In 1799 he entered the University of Lund, where he studied theology and philosophy, and became 'Adjunkt' of Æsthetics in 1805, and Professor of Greek in 1812. After he had been elected to the Swedish Academy (1818), and graduated in theology, he was appointed Bishop of Wexiö, where he died, November 2, 1846. The first great works of T. were his *Svea* (1811), crowned by the Academy; the idyl *Nattvardsbarnen* (1821; Ger. trans. by Möhnike, 5th ed. Halle, 1876), and *Axel* (1822; Ger. trans. by Vogel, Leip.

1876), whose subject is drawn from the age of Karl XII. It was by his *Frithjofs Saga* (1825; *ed. de luxe* by Malmström, 1868) that T. won his highest fame. This poem has been translated into almost every European language. Its German translations number nineteen, of which the best are by Simrock (3d ed. Stuttg. 1875), Zoller (Leip. 1875), Von Kleinburg (9th ed. Berl. 1875), and Möhnike (14th ed. Leip. 1877). Two works left incomplete at his death are *Helgönabacken* and *Gerda*, the latter an epos placed in the time of Valdemar the Great. T.'s *Samlade skrifter* have been published by his son-in-law Böttiger (7 vols. Stockh. 1847-50; last ed. 4 vols. 1871-72), and his posthumous works by El. Tegnér (3 vols. 1873-74). In poetry T. holds a place between the blind imitators of French models and the 'New School' of Atterbom, that found its ideal in German Romanticism. His rich humour and lively fancy, his warm and manly feeling, and his wealth of high thoughts expressed in noble forms, entitle T. to rank among the greatest of recent poets. His minor pieces are instinct with strength and freedom, and move with the easiest idyllic grace. The critic Georg Brandes, in a monograph on T. published in 1878, ranks him as a poet below Runeberg and Bellman, but thinks he is 'far more genuine' than they, 'a whole man; an honest, ingenuous mind with an ardent love for the beautiful and true.' See Böttiger, *Teckning af T.'s Lefnad;* Waldeck, T.'s *Stellung zur Theologie und Philosophie* (Stuttg. 1863); and Brandes in the *Deutsche Rundschau* for May 1878.

Teheran', the capital of Persia, province of Irak-Ajemi, in a sandy, stony plain which is 3447 feet above the sea, and stretches along the S. base of the Elburz Mountains (q. v.), 70 miles S. of the Caspian Sea. It is girt by a mud wall 4 miles in circuit, 20 feet high, and pierced by five gates; and the houses, mostly insignificant, mud-built structures, are ranged in narrow, crooked, filthy streets. On the N. side is the great fortified palace of the Shah, around the gardens of which are ranged the mint, prison, military school, &c. T. has eleven mosques, several of imposing appearance, various theological schools, a teachers' training-school, with library (founded 1850), large modern bazaars (notably Taki-Khan, finished 1851, at a cost of £30,000), numerous caravanserais, and baths. Within the town, especially in the N., are many fine gardens. In the vicinity are the Shah's palaces of Negristan and Niaveran, and the ruins of *Rhagä*, the *Rhages* of the Apocrypha, the classical *Ragæ* and the birthplace of Harun-al-Raschid. T. is the centre of a considerable trade with Europe, carried over the route from Poti on the Black Sea *viâ* Tiflis, Tabriz, and Kazbin. It manufactures iron-wares, tapestry, silks, and (since 1861) cottons. Pop. 80,000, greatly increased during the presence of the court in winter. The wealthier citizens are driven to the hills in the N.W. early in spring by the intolerable heat and bad exhalations. T. was chosen as a residence by the Shah in 1796, its sole recommendation being its proximity to his ancestral tribe, the Kujjurs. The Russian government has arranged to continue the Poti-Tiflis railway to T., and in addition has projected another line thence from Enzele, a Caspian port near Reshdt. The surveys of the latter line were completed by Austrian engineers in December 1878, and, by agreement with the Shah, the first sod is to be cut on March 2, 1879. The work, it is calculated, will take two and a half years, at the end of which an extension is to be made from T. to Bushire within the following three years. The whole line, linking the Caspian and Persian Gulf, is to be opened by 1887.

Tehuantepec', a town on the Pacific coast of Mexico, on the isthmus of the same name. It stands on the T. river, 11 miles above where it enters the great Gulf of T. The town has sixteen churches, including one erected in 1530 by the native tribe of the Zapotecos. Leather, cotton, salt, and indigo manufactures and pearl fisheries are the main industries. The pop., which is composed of Indians and half-breeds, and a few of pure Castilian blood, is about 14,000. The Isthmus of T. is a strip of Central America between the Gulf of T. and the Gulf of Mexico. The total distance across from N. to S. is only 143½ miles. The range of the Cordilleras is here suddenly broken for about 20 miles. Moreover, the river Coatzacoalcos, navigable for ships for 30 miles, flows in the line of the Isthmus into the Gulf of Mexico. Hence frequent efforts have been made to carry a railway or a ship-canal across the Isthmus. In 1814 the Spanish Cortes authorised the making of a canal. Other efforts have since been made. A United States company (the T. Railway Company) got a concession in 1867. The United States Government had it surveyed, with a view to a ship-canal, in 1870-71 by Captain Shufeldt. See *Reports of Exploration*, &c., *Ex. Doc. No. 6* *Senate*. See also *Isthmus of T.*, by Major Barnard (New York, 1855).

Te Ig'itur, one of the service-books of the Roman-Catholic Church, is properly an extract from the Missal. It contains the canon of the Mass, from the first words of which—*Te igitur, Clementissime Pater*—it derives its name, and certain other portions of the Liturgy which do not vary with the seasons or the festivals.

Teign'mouth, a seaport and watering-place of S. Devon, 15 miles S. of Exeter by rail, stands on the N. bank of the mouth of the Teign, which is here spanned by a bridge (1827) 557 yards long. Numerous villas have sprung up on the hills to the N. and along the 'Den,' a public lawn stretching ¾ths of a mile above the beach, and a promenade pier was constructed (1866). The two Anglican churches, St. Michael (with a good chancel 1872) and St. James, are poor edifices of the early part of the present century; but a fine Roman Catholic church, in Geometrical Decorated style, has been built (1878) in connection with St. Scholastica's Abbey (1865). Other buildings are the public assembly rooms (1826), theatre (1849), market-house, public baths, &c. Beyond shipbuilding (6 sailing vessels of 400 tons in 1873-77) and fishing (employing 476 hands in 1878), T. has no special industries, but there is a considerable trade, its harbour being entered (1877) by 470 vessels of 53,163 tons and cleared by 375 of 38,476, whilst on December 31 of that year 46 ships and 116 fishing-boats were registered as belonging to the port. The exports (pipe and potter's clay and granite) amounted (1877) to £5934; the imports (coal, culm, timber, &c.) to £50,583, the customs to £2280. T. publishes three weekly newspapers, and has a pop. (1871) of 6751. T. was burnt by the Danes (930) and French (1338 and 1690), on the last occasion losing 116 houses.

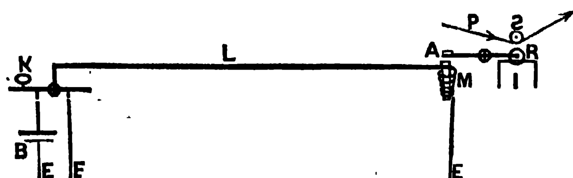
Teign'mouth, Lord. See SHORE, SIR JOHN.

Teinds (Mœso-Goth. *taihund*, 'the tenth part'), the name given in Scottish law to Tithes (q. v.). *Personal* T. are unknown in Scotland. *Predial* T., which affect the fruits of the land, are either *natural* or *industrial*, of which the industrial correspond to *mixed* tithes. In Scotland, until T. came to be regulated by the valued rental, there was hardly any teinding of *natural* fruits, so that predial tithes of industrial fruits have all along, with a few local and consuetudinary exceptions, constituted the whole T. leviable by the Church in Scotland. T. are *debita fructuum*, not *debita fundi* (see DEBITUM FUNDI); their arrears therefore do not affect a Singular Successor (q. v.). Formerly there were in Scotland two classes of clergymen. There were the clergy of the *mensal* churches, *i.e.*, churches, during the time of Episcopacy, appropriated by the patron to the bishop as part of his benefice. These, as regards their incomes or stipends (see STIPEND), were, between the Reformation and the abolition of Episcopacy, at the mercy sometimes of the bishops, at others of the Crown. They have now permanent stipends allotted to them by commissions from the bishops' tithes, now attached to the Crown. The second class whose stipends had never since their original appointment been given out remained proprietors of the full T. until it was given in 1649 to the patron, as a solatium for his loss of presentation; while a stated provision for the clergy was imposed as a burden on the patron on his retention of the T. after recovery of the right of presentation. Besides other powers granted to the commission of T. in 1633, they were authorised to affix reasonable stipends to the parochial clergy out of the tithes.' This power is now vested in the Court of Session (see AUGMENTATION, PROCESS OF). £150 is the minimum annual value of a church living in Scotland. If the T. are insufficient for this, the deficiency is made up by the Exchequer.

Tejucigal'pa, a town of Honduras, Central America, on the Rio Grande, 40 miles S.E. of Comayagua, is the capital of a department of the same name, and contains a university and cathedral. Though it has decayed considerably, owing partly to the emigration of some of the Spanish families, and partly to the exhaustion of the gold and silver mines, it is still an important city. Pop. 12,000.

Tek'eli. See TÖKÖLY.

Telamo'nes, the name given by the Romans to male colossal figures supporting balconies, cornices, &c., and thus corresponding to the Atlantes (q. v.) of the Greeks. They were so called after the mythic hero Telamon, the son of Æacus and father of Ajax by Peribœa, who was one of the Argonauts and Calydonian hunters, and accompanied Hercules in his expedition against Laomedon.



Tel'edu (*Mydaus meliceps*), a species of *Carnivorous* mammal found in Java, and allied to the Weasel (q. v.). Its colour is a blackish brown, the under parts being lighter. The feet and claws are large, and adapted for burrowing. The food consists chiefly of insects.

Tel'egraph (Greek, *tēle*, 'afar,' and *graphō*, 'I write') is any instrument fitted to convey intelligence beyond the limits of distance at which the voice is audible. Beacons, flags, trumpets, drums, gongs, guns, rockets, and other signals, have been and are still in certain circumstances used for purely telegraphic purposes, and of all such methods the most complete was the French Semaphore (q. v.) system, introduced by M. Chappe in 1794. The word *telegraph*, however, is now usually restricted in its application to the electric T., the history and nature of which we shall consider shortly. The first detailed scheme seems to have been described in a letter to *Scots Magazine*, written on February 1, 1753, from Renfrew, and signed C. M., the initials, according to Brewster, of one Charles Marshall. He suggested transmitting a charge from the conductor of an electrical machine at the sending station along an insulated wire to a conductor at the receiving station, the presence of the charge being indicated by the behaviour of a light pith ball, or by the passage of a spark. Each letter of the alphabet was to have a separate wire, so that any word might be spelt out, and thus any message sent. The possibility of transmitting frictional electricity had been already demonstrated in 1747 by Dr. Watson, who exhibited electrical effects at a distance of 2 miles from the source of excitement. Schemes essentially the same in principle, but differing in more or less detail from the above, were suggested and experimentally tested by Lesage (1774), Lomond (1787), Reusser and Böckman (1794), Cavallo (1795), Salva (1796), Bétancourt (1798), and Ronalds (1816); but an insurmountable difficulty in all these attempts was the impossibility of securing a sufficiently good insulation for long distances. More easily managed in this respect was current electricity, which, though discovered by Galvani in 1791, was of no practical interest till Volta in 1800 afforded an easy means for its production by the invention of the cell and battery. But how was the passage of a current in a conductor to be detected? Its physiological action, as in Galvani's original experiment, was very slight for weak currents, as also its decomposition of water, which, Sömmering employed in 1809, and the expense of maintaining a powerful current through a long length of circuit rendered such methods impracticable. With Œrsted's great discovery, however, of the action of a current upon a magnet in its vicinity (1820), we enter upon a new and more hopeful epoch. In that year Ampère and Ritchie attained a certain success in the construction of a telegraphic model with 30 needles and 60 wires, and in 1829 Fechner devised a similar T. of 24 needles and 48 wires. The expense of such complicated apparatus, however, was still too great. In 1832 the idea occurred to Baron Schilling von Canstadt of using simply one needle and two wires, and of expressing the different letters of the alphabet by different combinations of right and left deflections, produced by sending the current round the circuit, first in one direction, then in the other. Before he had tested this idea experimentally, Gauss and Weber, in 1833, had stretched two wires from the observatory to the physical cabinet at Göttingen, and at their suggestion Steinheil, in 1837, constructed a similar T. between the Academy at Munich and the observatory at Bogenhausen, 3½ miles distant. These physicists employed magneto-electric instead of voltaic currents. The last named also discovered that a return wire was unnecessary if the extremities of the other wires were taken to earth, and devised a method for automatically registering the communication upon a strip of paper moved uniformly along by clockwork. Meanwhile in England Cooke and Wheatstone were patenting their five-needle T., an improvement upon Schilling's apparatus, a model of which Cooke had seen at Heidelberg in 1836. The twenty necessary letters of the alphabet (*c*, *j*, *q*, *u*, *x*, *z* were not represented) were indicated by the mutual convergence of two of the five needles, each of which, with its corresponding needle at the other station, was worked by a separate wire. This was really the first successful working T., and was erected on a portion of the Great Western Railway between Paddington and Slough, a distance of nearly 20 miles. To Wheatstone is also due the construction of the alarm or electric bell, worked by means of an electro-magnet. To the other extremity of the hammer of the bell a piece of soft iron is attached, which is set opposite to the pole or poles of an electro-magnet (see ELECTRICITY and MAGNETISM). Each station is provided with such an apparatus, which is worked by the current from the other station. When the current passes through the electro-magnet coil, the soft iron armature is attracted to the electro-magnet, and the hammer is simultaneously raised. This action, however, by a simple device breaks the circuit, the electro-magnet ceases to act, the soft iron armature is released, and the hammer by its own weight returns to its normal position, at the same instant giving the alarm. Simultaneously the circuit is again completed, and the hammer raised to once more break the circuit and descend to give the alarm, and thus the action automatically repeats itself till the attention of the operator is directed to it. Other forms of bell have been invented by later electricians. Cooke and Wheatstone's original T., however, and their later letter-showing dial T. (1839), in which, by the action of an electro-magnetic touch upon the pullets of an escapement moved by clockwork, the letters of a given word appeared successively at an opening in the dial, were too cumbersome and expensive to allow of more than a restricted use. Nevertheless, their success was sufficient to warrant the formation of an Electric T. Company, which bought Cooke and Wheatstone's earlier patents for £120,000, and was soon involved in lawsuits with other inventors who were supposed to have infringed the patents. In this the company was generally unsuccessful; but by paying exorbitant prices to the inventors, or by compounding with them in some way, it managed for a time to secure a monopoly. One of its most formidable competitors was Alexander Bain, an Edinburgh watchmaker, and he was made a director, receiving at the same time £12,000 for his chemical printer. Nott and Gamble, Highton, Ward, Holmes, Henley, and Foster are the most important of Wheatstone's early contemporaries, but it is impossible here to do more than mention them. Of Wheatstone's own later improvements and inventions, the single and double needle instruments may be here noticed. In these the different letters were represented by different combinations of right and left deflections, produced on the needles at the sending and receiving stations by the current which by a simple arrangement could be sent round the circuit in either direction. These needles, however, required a considerable strength of current to move them; and to send such a current directly through a long circuit was not only expensive, but would have proved injurious to the material composing the circuit. To meet this difficulty Wheatstone invented the *relay*, which by a simple electro-magnetic arrangement substitutes for the weakened current a stronger current from a local battery. By these later improvements, Wheatstone did much to simplify the methods of telegraphy; but still simpler, inasmuch as it requires no reversal of current, is the 'dot-and-dash' system introduced by Morse in America about 1836. The alphabet code was similar in principle to Wheatstone's later right-and-left combinations, only instead of right-and-left deflections short and long currents were used, by combining which, two, three, and four together, all the letters could be represented. Representing the short current by a *dot*, and the long current by a *dash*, the Morse international code, which is now universally employed, is as follows:—

a	·—	j	·———	s	···
ä	·—·—	k	—·· ·	t	—
b	—···	l	·—··	u	··—
c	—·—·	m	——	ü	··——
d	—··	n	—·	v	···—
e	·	ñ	——·——	w	·——
é	··—·	o	———	x	—··—
f	··—·	ö	———·	y	—·——
g	——·	p	·——·	z	——··
h	····	q	——·—	ch	————
i	··	r	·—·		

1	· — — — —	6	— · · · ·
2	· · — — —	7	— — · · ·
3	· · · — —	8	— — — · ·
4	· · · · —	9	— — — — ·
5	· · · · ·	10	— — — — —

Having thus traced the rise of telegraphy, it remains to discuss in more detail the forms of apparatus which are generally used. Telegraphic instruments may be divided into two great classes—those which transmit signals by purely conventional signs, *i.e.*, by means of a code; and those which show and record the signals by means of the ordinary letters of the alphabet. Those belonging to the former class have the advantage of simplicity; while those belonging to the latter have the advantage of less chance of error, and do not require special training to read the messages as they are received. For general telegraphic business the first class of instruments is the best; and in these all signals are made by alternately breaking and making the current. The code is made up of combinations of long and short currents, as in the Morse alphabet, or of combinations of positive and negative currents, as in Wheatstone's single-needle T. In the Morse T., the operator, when he wishes to send a current, simply depresses a key, which when released is brought back to its original position by means of a spring, so that the current is interrupted. A short depression gives the *dot*, a longer the *dash*. At the receiving end dots and dashes corresponding exactly to the short and long currents are impressed upon a

long strip of paper by a very simple device, the principle of which is shown in the figure. By pressing down the key K, the line L is connected with the one pole of the battery B, whose other pole is to earth. Since the other end of L is also to earth, a current flows as long as K is kept down. This current at the receiving station is directed round the coil of an electro-magnet (M), which attracts the armature A to it as long as the current flows. This armature is attached to the one end of a lever which works on a central pivot, and which has at its other extremity a narrow roller R. This roller is continually revolving in an ink-trough I, out of which it is raised when the armature A is attracted by the electro-magnet. This action brings the inked roller into contact with the strip of paper P, which is being moved uniformly along by clockwork in the direction of the arrow-heads. The longer the duration of the current, the longer the electro-magnet keeps the armature depressed, and the longer the ink-mark upon the paper which is moving uniformly on the roller S. A complete Morse ink-writer, as used in practice, combines of course the clockwork by which both the roller and paper are kept in motion. Instead of an inked roller, a style making an indentation may be and was formerly employed; but in all, the principle of action is essentially that described above. Bain's chemical T. may be substituted for the Morse receiving instrument, and in it no electro-magnet is required. The current is directed through a steel style which presses upon a strip of paper soaked in a mixed saturated solution of ferrocyanide of potassium and nitrate of ammonia. The style and paper together press upon a metallic surface, over which the paper is drawn by clockwork, and through which the current after traversing the style and paper finds its way to earth. The passage of the current through the paper is accompanied by a chemical reaction between the salts present forming Prussian blue, so that the short and long signals are represented by blue dots and dashes. As already pointed out, for long distances the *relay* is used for retransmitting the original signal from a fresh battery. The ordinary Morse ink-writer can easily be arranged as a relay, so that the same action which registers the message at one station retransmits the message from that station to a farther one, and so on. On the Indo-European line from London to Teheran there are five relay stations in the circuit. A simple Morse or single-needle instrument can be worked by a skilled operator at the rate of about 30 words per minute, while receiving instruments can record more than 100 words per minute. To increase the rate of sending, electricians have devised automatic transmitters, the most successful of which is Sir Charles Wheatstone's. In it the order and succession of the currents are determined by perforated bands of paper, which are prepared beforehand by means of the *perforator*. Each strip is perforated in three rows of holes. The holes in the central row are uniformly spaced. Those on either side are not so, but represent the Morse dots and dashes according to the side on which they are. The strips of paper so prepared are then inserted into the *transmitter*, the uniformly-spaced central holes serving to move the paper on at a constant rate. Whenever a side hole comes, contact is made through it by means of a little metallic plunger; and according to the side on which the hole is, the resulting current is in the positive or negative direction. A slight modification renders Wheatstone's automatic transmittor applicable to the short and long Morse signals instead of the positive and negative signals. Of the second class of telegraphic instruments, Wheatstone's letter-showing T. has been already mentioned; and a modification of it is not uncommon for private lines in large establishments. It simply shows the letters, and does not print them. The typical telegraphic printer is Hughes' T., invented in 1855. The essential principle is the synchronous movement of two constantly revolving type-wheels, with correspondingly situated letters on their circumferences, at two different stations. There is a circular row of twenty-eight vertical pins connected with the same number of piano-keys. The depression of a key raises the corresponding pin, which is thus brought into contact with the revolving contact-maker at the very instant that the corresponding type on the synchronously revolving type-wheels at both stations is passing the roller over which the strip of paper is stretched. At this instant the paper is struck against the edge of the rotating wheel, and the letter printed without the wheel being sensibly retarded. The paper is then pulled on a step by clockwork, to be in readiness for the next letter. Various modifications and improvements have been introduced by other inventors, especially in America, where the names of Phelps, Edison, Gray, and others attest their activity in this direction. The autographic processes of Bakewell, Caselli, and Bonelli depend also upon synchronous motion at the two ends of the line, the writing-like impression being made on chemically prepared paper, as in Bain's early form of T. The introduction of *duplex* telegraphy, by which messages can be sent in both directions simultaneously through the same wire, has greatly increased the transmitting power of telegraphic lines. The method by which this is most easily effected is by splitting up the current at the sending station into two portions, which affect the needle in opposite directions, and only one of which is transmitted along the line to the receiving end, the other being taken directly to earth. The current, then, which acts upon the needle at the receiving end has no effect at all upon the needle at the sending end, which is thus free to be acted upon by a simultaneous current which, split up similarly and unaffecting its needle, is transmitted from the other end. In 1874 Edison invented a method of sending two messages in the *same* direction simultaneously, so that quadruplex telegraphy is now an accomplished fact. Elisha Gray of Chicago has succeeded in sending as many as eight messages along a wire at once by introducing the currents into the circuit through vibrating reeds tuned to different pitch. At the receiving end are exactly similar and similarly-tuned reeds, each of which picks out its own current, vibrating only when a current has entered at the sending station through its corresponding reed. This ingenious method evidently admits of great development.

Submarine T.—On land the wires are usually stretched on insulating supports fixed upon tall poles, and are uncovered by insulating material, the atmosphere being a sufficiently good insulator to prevent rapid leaking. When, however, schemes were suggested for carrying lines under rivers, lakes, or seas, it was found necessary to cover the wire with an insulating material, the most convenient one being indiarubber or gutta-percha. One of the greatest scientific triumphs of the present century was laying a telegraphic cable across the Atlantic so as to bind Europe and America together in close communication. When a signal is sent through such a cable, a measurable in-

terval of time elapses before it produces any effect on the distant end; and, further, when this effect at length appears, it is found to grow gradually to a maximum. The maximum effect occurs at the receiving end of an Atlantic cable about three seconds after the signal is sent from the sending end. After the signal is sent, the sending end is put to earth, and the cable allowed to empty itself, in doing which the current falls off to a minimum according to exactly the same law by which it formerly attained its maximum. There is thus a limit to the speed of signalling in such cables. Further, the leakage is so great for a long cable that the ordinary modes of registering fail, and other more delicate methods must be supplied. The practical realisation of this department of telegraphy is due more to Sir W. Thomson and C. F. Varley than to any other electrician that could be named. The delicate recorders invented by the former are now at use at all cable stations, and these merit a few words of explanation. The mirror galvanometer (see ELECTRICITY), now an indispensable instrument in every physical laboratory, was constructed at first solely for cable use. The delicately-poised mirror, backed by minute magnets, answered at once to the weakened cable current, and from its right and left deflections, indicated by a beam of light reflected upon a screen, gave the message made up according to the Morse alphabet code. Far more delicate, however, is Thomson's siphon recorder, which records the right and left deflections by means of a jet of ink spurted from a fine glass siphon attached to a light coil which, suspended between the poles of a powerful electro-magnet, swings to one or other side according to the direction of the feeble cable current which is passed through it. The ink is ejected only when electrified, and is received upon a passing strip of paper. When no message is being sent, the record appears upon the paper as a straight line; but when the interrupted currents pass through the coil, the record appears as a wavy line —waves to the right representing the *dot*, waves to the left the *dash*. A full description of the most recent improvements will be found in a pamphlet by J. A. Ewing (1876), in which also the *automatic curb sender* of Thomson and Jenkin is described for the first time. The principle of this latter instrument is to send into the cable a second reversed current, which, by neutralising the bad effects resulting from the gradual diminution of the first charge, brings the siphon quickly back to zero, and increases the speed of signalling.

According to the latest returns for the various countries of the world, published in the *Almanac de Gotha* for 1879, the total length of telegraphic lines over the globe is 431,761 miles, divided amongst the several continents as follows:—Africa, 7999 miles; America, 127,980 miles; Asia, 24,760 miles; Australasia, 36,692 miles; Europe, 234,330 miles. The total length of wireage may be estimated at about three times this length; and most of these lines are in the hands of the Governments of the different countries. The total mileage of telegraphic cable is estimated at 230,089 miles.

There is now an extensive literature on the subject, including the bi-monthly *Telegraphic Journal* (Lond.), the weekly *Telegrapher* (New York), and the bi-monthly *Annales Télégraphiques* (Par.). See also *History and Progress of the Electric T.*, by R. Sabine (2d ed. Lond. and New York 1869), *Telegraphy* by W. H. Preece and J. Sivewright (Lond. 1876), *History, Theory, and Practice of the Electric T.* (Boston 1865), and *Electricity and the Electric T.* (New York 1877), both by G. B. Prescott, *Handbuch der Elektrischen Telegraphie*, by E. K. Zetzsche (Berl. 1876), *Traité de Télégraphie Electrique*, by Du Moncel (Par. 1864), and *Les Systèmes Télégraphiques*, by C. Bontemps (Par. 1876). The theoretical results of Sir W. Thomson are best studied in his own published papers or in Clerk Maxwell's *Electricity and Magnetism* (1873).

Tel'egu (said to be derived from Telinga = the three *lingas*, or emblems of Siva), a language belonging to the Dravidian (q. v.) branch of the Turanian family. It is chiefly spoken in the N.E. portion of the Madras Presidency, by an estimated pop. of 12,000,000.

Telem'achus, son of Ulysses and Penelope, was still a child when his father sailed for the Trojan War, but coming to man's estate, received from Athene counsel to wander forth and inquire Ulysses' fate. Disguised as Mentes or Mentor the Taphian king, the goddess herself guided him first to Nestor of Pylos, then to the Spartan Menelaus, and from the latter he learnt the Protean prophecy of his father's safe return. So hastening back to Ithaca, T. found Ulysses in the swineherd Eumaeus' hut, and aided him in the destruction of the suitors. Fénelon (q. v.) made his adventures the theme of a romance, which was once extremely popular, but which has very little merit.

Teleol'ogy (*telos*, 'an end') is a philosophical and theological term meaning the Science of the Ends for which things exist or were created. Like very many other terms in current use, it is derived, or at least first gets scientific meaning and precision in the system of Aristotle. According to that philosopher, the *telos*, or end of anything, is that for the sake of which it exists—it is at once cause and consummation. In modern times the argument that affirms design in nature—some divine plan 'to which the whole creation moves'—is called the teleological argument. Of this there are two phases which should be carefully distinguished: 1. The lower, which asserts that all the apparatus of nature were each definitely created for the end which it fulfils. To take a trite example, the camel was created to be of use to men so unfortunate as to dwell in a desert. But the obvious reply to this is that the same end might have been gained by the simple expedient of not creating the desert, 2. The higher, which asserts that a higher power may work towards a definite end by means of this and other natural laws. The great objection to this is the moral difficulty, *i.e.*, the relation between the good and the facts of existence; but here also the strongest support for it lies, for while the 'struggle for existence' does not seem to be arranged on purely moral grounds, yet it is in the facts of our moral life that the strongest presumption of an ultimate T. lies.

Teleosau'rus, a genus of fossil *Crocodilia* (q. v.), belonging to the section *Amphicœlia*, in which the bodies of the vertebræ were concave at either extremity, a conformation indicating their adaptation to an aquatic life. The hind limbs were well developed, the snout was prolonged after the fashion of the living Gavial (q. v.) of the Ganges, and teeth were numerous and slender. The remains of T. occur in Oolitic rocks.

Teleos'tei, a well-known order of fishes, including all familiar food-fishes, and such generally as have a well-developed bony skeleton. The T. include the Malacopteri (q. v.), Anacanthini, Acanthopterygii (q. v.), Lophobranchii (q. v.), Plectognathi (q. v.). *Fossil T.* are first found in the Cretaceous rocks, and exist in their maximum development in the oceans of to-day.

Tel'ephone (Gr. *tēle*, 'afar,' *phōnē*, 'sound') is any apparatus for transmitting sound beyond its natural limits of audibility. Thus, a stretched cord or wire may be used for carrying a whisper several hundreds of feet, and constitutes therefore a T. Of late, however, the word has been restricted to an instrument which can effect the same to a more wonderful extent, and that by electric means. In 1860 Reis invented an apparatus by means of which a musical note could be transmitted along a telegraphic line and heard easily at a distant station. At the one station a note was sounded close to a stretched membrane, which set into synchronous vibrations, completed and interrupted a circuit, through which consequently a discontinuous current flowed to the other station. Here it passed round a cylindrical coil, through the centre of which was drawn a thin iron rod, which was thus magnetised and demagnetised at every make and break of the circuit. Now such an iron rod when so treated gives a distinct click at every change of magnetic condition, the louder being when the circuit is made. Hence, if the making and breaking is sufficiently rapid, the corresponding clicks will combine to form a musical note, and this is precisely the action of Reis's T. In it, however, only the *pitch* of the note originally sounded is reproduced, and where the reproduction is effected by means of a *discontinuous* current we cannot hope for more than this, so that to reproduce a sound exactly as uttered is not possible upon the make-and-break principle. In 1876, however, Professor Graham Bell, a Scotchman resident in Boston, U.S., invented an *articulating* T., which depends upon the principle of the *undulating* current, and by means of which the very quality of a note, and therefore conversation itself, can be reproduced at a distant station. Bell was led to his discovery in his endeavours to discover an efficient means of multiplex telegraphy, and the essence of his first patent (February 14, 1876) is the employment of an undulating induced current produced by the oscillation of a magnetic diaphragm or tuning-fork in the vicinity of a coil of

wire. This oscillation may be produced by the human voice or by a musical instrument sounded near the diaphragm; and the undulating induced currents directed along a wire to the receiving end exactly undo what was done at the sending end—they set the diaphragm into oscillations which, transferred to the air, reproduce the original sound exactly as uttered. Such is the principle upon which the Bell T. works (see MAGNETISM). At the same time that Bell was developing his idea, Elisha Gray was working in the same direction, and in his patent of 1876 he indicated a method by which sounds might be accurately transmitted. His method depends upon a varying resistance, while Graham Bell's depends upon a varying electromotive force. The *practical* utilisation of a varying resistance is, however, really due to Edison, the inventor of the phonograph. His carbon T. utilises the property which carbon has of altering its resistance with pressure. The variation in pressure is produced by the sounds spoken to the one surface of the carbon, and the consequent variation in resistance is accompanied by a corresponding change in the intensity of the current which is directed through the carbon from a battery to the wire which leads to the distant station. There the undulating current is retransformed into the sound by means of an ordinary Bell magneto-electric T., which Edison claims to have first used as a receiver. For a detailed discussion of the claims of these gentlemen, see Prescott's *The Speaking T., Talking Phonograph, and other Novelties* (1878) and Du Moncel's *Le Téléphone, le Microphone, et le Phonograph* (1878). The microphone is an instrument by which sound is magnified, and was invented by Hughes in April of 1878. It depends upon considerable variations, produced by slight sounds, in the resistance of a circuit traversed by a current, the resulting changes in the intensity of the current being heard in a Bell T. which forms part of a circuit. The variations of resistance are produced by the variations in loose contacts at a certain part of a circuit—as, for instance, a few nails or pieces of carbon touching each other loosely. The most homely of microphones is no doubt the rough box of moistened cinders used by Blyth of Edinburgh (see *Transactions of the Royal Society of Edinburgh*, 1877-78). What the future of these instruments may be it is impossible to say, but it is within the limits of probability that a loud-speaking T., such as Edison's carbon instrument, with a phonograph to record the messages sent, may ultimately supersede ordinary telegraphing by conventional codes.

Teleph'orus, a genus of *Pentamerous* beetles, including numerous British species. They have long narrow-shaped bodies. The larvæ are found in the earth, and the adults are insect-feeders.

Teler'peton, a curious extinct genus of *Reptilia*, the remains of which occur in certain sandstones of Triassic or Devonian age. T. remains have been found near Elgin in Scotland. These creatures had *acrodont* teeth—that is, teeth attached to the summit of the jawbones—and *amphicœlous* vertebræ, lizards having, as a rule, *procœlous* vertebræ. Professor Owen calls T. *Leptopleuron lacertinum*. There were twenty-six vertebræ between skull and sacrum, two sacral vertebræ, and thirteen caudal vertebræ. Impressions of twenty-one pieces of ribs are preserved.

Tel'escope (Gr. *tēle*, 'afar,' and *skopeō*, 'I see') is an instrument for viewing objects at a distance. All such instruments may be grouped in two classes, according as they are *refracting* or *reflecting* telescopes. In the former, the purpose is effected by a combination of optical lenses (see LENS); in the latter a curved reflecting surface or speculum takes the place of one or more of the lenses. The principle of the T. seems to have been known to Roger Bacon (*d.* 1292); and in 1570 Dr. Dee, in his preface to *Euclid's Elements*, suggests that a commander may reconnoitre a distant army by means of 'perspective glasses.' It was not, however, till about 1608 that the construction of the T. was effected; and three Dutchmen seem to have made the discovery independently about the same time, Lippersheim, Metius, and Jansen. Their claims are discussed by Humboldt in his *Cosmos* (vol. ii.). When the news of the discovery reached Italy, Galileo at once saw what the essential conditions of such an instrument must be, and setting to work soon completed a T. for his own use. It consisted of two lenses, a double-convex object-glass, and a double concave eye-glass of much shorter focus. The converging rays from the object-glass are received before they meet at the focus by the concave lens, which is set so as to make the rays continue in parallel lines. With such an instrument Galileo made all his great astronomical discoveries. Instead of the concave lens, a convex lens may be used as an eye-glass, if it is set on the *further* side of the focus, so as to reduce the now diverging rays to parallelness. This form of T. was described by Kepler, and first constructed by Scheiner in 1650. Its disadvantages as compared with the Galilean T. are that it is not so compact, and that the image is inverted and not so clear. It possesses certain advantages over the latter, however, such as offering a larger field of view and being more effectual in very faint light, advantages which have established it as the *astronomical T.* The Galilean T. is familiar in the binocular opera-glasses. The magnifying power of a simple astronomical or Galilean T. is equal to the ratio of the focal lengths of the lenses, and is increased if the focal distance of the object-glass is increased, or if that of the eye-glass is diminished. There is of course a practical limit to the latter operation; so that astronomers, in their attempts to increase the magnifying power of their telescopes, had to make the object-glass with as long a focal length as possible. Thus in 1672 Campani constructed one 136 feet long, Auzont used one of 600 feet (a tube in such a case was out of the question), while Huyghens' 123 feet long T. is still preserved by the Royal Society of London. Huyghens showed how to increase the distinctness of such a T. by using a particular form of eye-piece, hence called Huyghens' eye-piece. There were, however, defects in the object-glass which Huyghens was unable to eradicate—namely, spherical and chromatic aberration (see ABERRATION). Newton succeeded in eliminating the former by making the lens a particular form, but its elimination only brought into more prominent view the latter and worse defect. Since each lens acts as a prism to the rays passing through it, the image becomes fringed with colours, a defect very observable in long focussed lenses. This is a necessary consequence of the different refrangibilities of the different coloured rays of light, so that the focus, instead of being a single bright spot, is drawn out into a chromatic line with the violet end nearest the lens. The length of this focal line is called the dispersion, and from one experiment Newton hastily concluded that the dispersion was proportional to the deviation, and that therefore dispersion must always accompany refraction. This conclusion was subsequently disproved by Dollond, who showed that dispersive powers differed widely for different substances. Thus the dispersive powers of *crown* and *flint* glass are as 3:4, so that by combining a convex lens of the former of 3 feet focal distance, with a concave lens of the latter of 4 feet focal distance, the dispersion is reduced to zero, while the focal distance of the compound lens is 12 feet. In this way Dollond practically solved the problem of the achromatic telescope. All good refracting telescopes are made with achromatic object-glasses. For ordinary terrestrial purposes, two lenses, at least, must be added to the eye-piece, one to reinvert the inverted image formed in the usual way, the other to view this second image. Thus a direct image is obtained. Dollond's four-glass eye-piece combines this reinverting principle with the principle of the Huyghenian eye-piece.

When Newton, from his having accidentally experimented with two substances of the same dispersive power, failed in eliminating chromatic aberration, he turned his attention to the construction of the reflecting T.; and to him is due the honour of having first constructed a reflecting T., a form of which had already been proposed by Gregory. Instead of the convex object lens of the refractory T. a concave reflector is substituted; and since all rays of light obey the same law of reflection, there is no chromatic aberration. For spherical reflectors, however, spherical aberration exists as in ordinary lenses; and to eliminate this defect for parallel rays the surface should be made a paraboloid of revolution. Three modifications of the reflecting T. exist, namely, the Newtonian, Gregorian, and Cassegrainian. The Newtonian reflector (1666) is the simplest in construction. The reflected rays are received on an inclined-plane mirror before they come to a focus, and are reflected to the side of the tube where the focussed image is viewed by an eye-piece as in the ordinary refracting T. In Herschel's great reflector of 4 feet diameter and 40 feet focal distance (erected 1787, dismantled 1822), there was no second reflector. The great reflector was slightly inclined so as to throw the image to the side of the tube

where it was viewed directly by means of the eye-piece. This modification is sometimes distinguished as the Herschellian T. In the Gregorian (1663), the concave mirror is perforated at the centre, and the reflected rays after meeting and diverging are received by a small concave mirror which directs them back through the central hole in the speculum, where they form a second image, which is then viewed by an ordinary eye-piece. The Cassegrainian (1672) differs from this only in having instead of a small concave mirror a small convex mirror, which is set so as to receive the rays from the great reflector before they meet. Reflectors are usually constructed upon the Newtonian principle, and of these the largest in existence is Lord Rosse's T., erected at Parsonstown, Ireland, in 1842. The speculum, an alloy of copper and tin, is 6 feet in diameter, with a focal length of 55 feet. The Melbourne reflector (1868) is a Cassegrainian reflector. Its speculum (also of copper and tin) is 4 feet in diameter and 30 feet 6 inches focal length. Specula are now made of silvered glass—a form first suggested by Foucault. The largest silvered-glass reflector, that in the Paris Observatory, is 47½ inches in diameter and 23 feet in focal distance, and was the work of Martin and Eichens. Lord Rosse's, at Birr Castle, constructed by himself, has an aperture of 36 inches. The construction of a speculum, 7 or 8 feet in diameter, has been undertaken by Grubb for a Californian observatory]; but the difficulty of polishing and firmly fixing such large surfaces is extremely great. An achromatic lens of equal diameter would be far superior to the reflector, since there is less loss of light, but the difficulties attending the construction of even much smaller lenses are still insurmountable. The largest refractor in present use, the Washington equatorial, constructed by A. Clark & Sons in 1873, has a clear aperture of only 26 inches, and a focal length of 31 feet 6 inches. Newall's refractor, constructed by Cook & Sons, York, has an object-glass of 25 inches diameter and 29 feet focal length. Grubb of Dublin is constructing a 27-inch T. for the Austro-Hungarian Government, the focal length of which is to be 32 feet; and A. Clark & Sons are engaged on a 28-inch aperture T. for Yale College. See Lockyer's *Star-Gazing* (1878) for a description of the methods of construction.

Tel'ford, Thomas, a celebrated engineer, was the son of a Scotch shepherd, and was born at Westerkirk, Eskdale, Dumfriesshire, August 9, 1757. At the age of fourteen he was apprenticed to a stone-mason, and after spending two years in Edinburgh removed to London in 1782. Five years later he was employed by Sir William Pulteney to make some alterations on Shrewsbury Castle, whereupon he settled at Shrewsbury, and was soon after appointed county surveyor, in which capacity he superintended the construction of a considerable number of bridges. His first great work, however, was the Ellesmere Canal, 103 miles long, begun in 1795 and completed in 1805. The Caledonian Canal, opened 1823, was also constructed by him, as also the Glasgow, Paisley, and Ardrossan Canal, the Macclesfield Canal, the Birmingham and Liverpool Junction Canal, the completion of the Gloucester and Berkeley Canal, and the entire remodelling of the Birmingham Canal. For the construction of the Gotha Canal in Sweden he received a Swedish order of knighthood. As engineer to the Commissioners of Highland Roads and Bridges he introduced important improvements in roadmaking, and his system is most strikingly presented in the great highway from London to Holyhead, executed in 1815. The Menai Suspension Bridge (1819-26) and the St. Catherine Docks, London (1828), are monuments of his genius in design and his skill in execution. Among his bridges the most notable are the Broomielaw at Glasgow, the Dean at Edinburgh, the Conway in N. Wales, the Ober at Gloucester. T. contributed several valuable articles to Brewster's *Edinburgh Encyclopædia*, and was frequently consulted upon important schemes, not only by the British Government but also by foreign powers, especially Russia. He died September 2, 1834, and was buried in Westminster Abbey. See *The Life of T. T., Civil Engineer, written by Himself* (1838); also Smiles' *Lives of the Engineers* (new ed. 1875).

Tell, the strip of land in Algeria lying between the mountains and the sea. It has an average breadth of 47 miles, with an area of 5400 sq. miles. It is well watered and very fertile, producing cereals, beans, tobacco, cotton, and wine, has rich pastures and luxuriant forests of oak and cedar, and contains the principal cities of Algeria.

Tell, William, the national hero of Switzerland, according to popular belief, was a native of the canton of Uri, who flourished about the beginning of the 14th c., with a great local reputation as a crossbow-man. Refusing to uncover his head before the ducal hat of Austria erected on a pole in the market, place at Altorf, he was dragged before the bailiff Gessler and ordered, on pain of death, to shoot an apple from his son's head. He performed the feat successfully, but having by a bold answer still further enraged Gessler, he was seized, bound, and thrown into a boat on the Lake of Lucerne in order to be taken to the castle of Küssnacht. A storm having arisen, T. was released and permitted to take the helm, but he ran the boat to a rocky ledge, from which he suddenly sprang ashore and escaped. He now lay in wait and shot the bailiff through the heart as he passed on the road between Arth and Küssnacht. Tradition tells nothing further of T. than that he was drowned in 1350 in the river Schlächen. Of the story of T. there is no mention in the four extant chronicles written in the first half of the 14th c., nor until 1470, the date of the *Weisse Buch*, which was discovered in the monastery at Sarnen. The story here differs in essential respects from the later form of the legend, and illustrates the manner of its growth. The name Wilhelm Tell appears for the first time in the *Tellenlied*, a ballad of 1470, which is alluded to in the chronicle of Melchior Russ, town-clerk of Lucerne, written in 1480. In 1507 appeared the chronicle of Petermann Etterlin, in which the story is given verbatim from the *Weisse Buch*, showing that that chronicle, though unpublished, had not remained unread. In 1515 a Latin poem was published on T. by a native of Glarus, and in 1540 appeared a play entitled *Ein hübsch spyl gehalten zu Ury in der Eydgnossnschafft von dem Wilhelm Thellen ihrem landtmann und ersten eydtgenossen*. In 1546 the story is given by Johann Stumpff in his *Chronick*, but it took its present form in the hands of the famous Ægidius Tschudi of Glarus in his *Chronicon Helveticum*, and received its final embellishment from the patriotic historian Johannes von Müller. The earliest expression of a doubt of the historical character of the story was given in 1607 by Willimann in a letter to his friend Goldast (published 1688). In 1754 Voltaire pointed out its suspicious character in his *Annales de l'Empire*, and in 1760 appeared a pamphlet with the title *Guillaume T., fable danoise*, by the Pastor Freudenberger, in which it is pointed out that a similar story is told of Toko or Tokko, and Harold, son of Gormson, King of Denmark, by Saxo Grammaticus, who flourished during the 12th c. The story, however, is also given in the *Vilkinasaga*, which appeared in the 13th c., and in which the actors are the archer Eigil or Ægel and King Nidung, as well as in our own 'north country' ballad, *Adam Bell, Clym of the Clough*, and *William of Cloudesley*, which is printed in Percy's *Reliques*. The story of the 'master-shot,' however, is not the common property alone of the Aryan races, but is, says Dr. Dasent, 'common to the Turks and Mongolians, while a legend of the wild Samoyeds, who never heard of T. or saw a book in their lives, relates it chapter and verse of one of their famous marksmen.' Swiss patriotism took umbrage at this attempt to deprive their country of its popular hero, but was singularly unfortunate in its attempts to establish his existence. The anonymous pamphlet of Freudenberger was burned by the public hangman at Uri, while a reply appeared written by the Vicar Imhoff, in which an account of T. is given, as is alleged, from an old manuscript, but which is a mere repetition of the version of Etterlin and Tschudi, while statements are quoted from spurious documents, and full belief is attached 'to the testimony, apparently dated 1460, in which one Johann von Brunnen alleges that he had found in an old paper the statement that the chapel built on the spot of T.'s leap, on the Lake of Uri, was erected by virtue of a decree issued by the Landesgemeinde, held in 1388, where there were present upwards of 114 persons who had known T.' Misguided patriotism, however, went farther than giving easy belief to vague assertions, as was discovered by Professor Kopp, for in the parochial register of Schladdorf, the name Walter von Trullo was altered into Walter von Tello, Näll was changed three times into Täll, while a document was forged purporting to contain a decree of the Landesgemeinde at Altorf, issued on Sunday, May 7, 1387, ordering a sermon to be preached yearly at the house of T., 'the first founder of their liberty.' The *Apfelschuss* of the Swiss archer must be laid aside as having any claim to be considered as a genuine historical fact,

but it has been for ever enshrined in the noble drama of Schiller. See Dr. Ideler, *Die Sage von dem Schusz des T.* (Berl. 1826); Dr. Huber, *Die Waldstätte bis zur Begründung ihrer Eidgenossenschaft* (Innsbr. 1861); Dr. W. Vischer, *Die Sage von der Befreiung der Waldstatte* (Leips. 1867); and M. Albert Rilliet, *Les Origines de la Confédération Suisse, Histoire et Légende* (Gen. 1868, 2d ed. 1869), the most exhaustive work on the subject. See also the *Edinburgh Review* for January 1869, the Introductory Essay to Dr. Dasent's *Popular Tales from the Norse* (new ed. Lond. 1864), and the introduction to Professor Buchheim's edition of Schiller's *Wilhelm T.* (Oxf. Clar. Press, 1871).

Tellez', Ga'briel, or **Tir'so de Moli'na** (to give him his more illustrious pseudonym), was born at Madrid in 1585, and in 1613 took the monastic vows, becoming Prior of Soria (1643), where he died in 1648. Author of some 300 comedies, this clerkly playwright is known to us now by but 68; these are enough, however, to show his original and many-sided genius, his bold invention, and his masterly analysis of character. In the *Burlador de Sevilla* he created the first 'Don Juan;' little inferior are his *Don Gil de las calzas verdes, El Amor Médico*, or *Marta la piadosa*. T. further wrote novels, and, more in accordance with his sacred calling, some *autos sacramentales* and other religious plays, these under his proper name. The best edition of his works is that by Hartzenbusch (12 vols. Mad. 1839-42; 2d ed. 1850).

Tell'icherry, a town in the district of Malabar, Madras Presidency, British India, 325 miles E.S.E. of Madras, and 64 N. from the railway terminus at Beypore. An English factory was established here as early as 1708. T. is celebrated for an unsuccessful siege (1779-82) by the troops of Hyder Ali. It is now an active seaport, chiefly for the export of coffee, sandalwood, and cardamoms from the Wynaud, and the import of rice. In 1874-75 the exports were valued at £483,000; the imports at £504,000. Pop. (1871) 20,504.

Tell'ing For'tunes. See FORTUNE-TELLING, CHEIROMANCY, &c.

Tellin'idæ, a family of *Lamellibranchiate* mollusca, belonging to the section of that class in which large respiratory *siphons* are developed. They have an equivalve shell, with the ligament on the thickest side of the shell. The mantle is widely open in front, and the siphons are long, slender, and separate.

Tellu'rium (Te = 129), an element sometimes classed as a metal, but more closely resembling selenium and sulphur in its chemical properties. It is obtained chiefly from Transylvania, where it is found in a certain gold ore associated with selenium. It has been found native, but usually occurs as a telluride of a metal, as in *graphic T.*, a black mineral containing tellurides of lead, silver, and gold. T. has a pinkish metallic lustre, is crystalline and brittle, fuses below a red heat, and volatilises into a yellow vapour at a high temperature. It burns in air with a green and blue flame, emitting fumes of tellurous acid (TeO_2), which is a feeble acid, but acts as a base with some of the stronger acids, forming a sulphate ($Te(SO_4)_2$) and nitrate ($Te(NO_3)_4$). Telluric acid (TeO_3), corresponding in composition to sulphuric acid, is also a weak acid, forming unstable tellurates, which are converted into the tellurites when heated. T. forms two solid chlorides, $TeCl_2$ and $TeCl_4$, the former of which, the *tellurous* chloride, is decomposed by water into T. and the *telluric* chloride. Telluretted hydrogen (H_2Te) closely resembles sulphuretted hydrogen in smell and other properties, precipitating tellurides when passed into solutions of metallic salts.

Tembu', Amatembu', or, more generally, **Tambu'kies**, a leading tribe in Kaffraria, said to be the oldest branch of the Kaffir race. Their territory, which lies at the head-waters of the Kei, Bashee, Tsomo, and other streams, has an area of about 4325 sq. miles, and is a plateau of moderate elevation, well watered and grassed, and fairly wooded. After the war of 1851, when their power was shattered, the T. remained quiet and friendly until 1878, when a section of them rebelled. They have large flocks and herds, and raise wheat, oats, and Kaffir corn in considerable quantities. Missionaries have met with much success among them. In 1876 the district was virtually annexed to Cape Colony, whose government is represented by a resident agent. Pop. about 80,000.

Temesvar', a town of Hungary, on the river Temes, 187½ miles S.E. of Pesth by rail, and 118½ N.W. of Orsova by a line opened in June 1878. The inner town is parted from four suburbs by a broad *glacis*, partly converted into pleasure-grounds, and the buildings include a Roman Catholic and a Greek cathedral, a splendid synagogue, the castle, built by Hunyades in 1443, and now a house of correction, two seminaries, and a theatre. There are manufactures of cloth, silk, leather, &c., and a lively trade in colonial wares. Pop. (1870) 32,223. T. was seized by the Turks (1552), but recaptured by Prince Eugene (1716), and in 1849 was vainly besieged by the insurgent Magyars for fifteen weeks.

Tem'pe, a narrow valley of north-eastern Thessaly, 4½ miles long, which, set between Ossa and Olympus, follows the windings of the river Peneus. The scenery, uniting soft beauty with rugged grandeur, was celebrated by many of the classic poets, who speak of T. as one of Apollo's favourite haunts.

Tem'perament (Lat. *temperamentum*), in music, the division of the octave into a number of intervals suited for musical purposes, to secure which the notes in certain instruments, such as the piano and organ, require to be regulated and adjusted. In the theory of harmonies the interval of a tone is not always the same, that lying between the fourth and fifth of the scale, for example, containing nine small differences or commas, whereas the interval between the fifth and sixth contains only eight commas. The diatonic semitone, again, contains five commas, and the chromatic semitone a smaller number, according to the magnitude of the tone. To improve the relations of these intervals by a sort of compromise is the work of T., which entails practically a new division of the octave. On the pianoforte, which is tuned by equal T., there are twelve equal intervals or semitones in the octave. The difference which exists in theory between two such notes as C♯ and D♭ is no longer recognised, one note doing for both. The consequence of this is that all the intervals are mathematically slightly incorrect, but that the errors are less noticeable than if some of the intervals had been made perfect at the expense of others. This latter system of unequal T. was formerly usual on the organ. One or two notes in the scale were absolutely correct, and the whole burden of the T. was placed upon the remainder. The keys in common use worked well, but those with more than three sharps or flats were so harsh and out of tune as to be almost unbearable. By the system of equal T. the individuality of the different keys is to a great extent lost, indeed it would vanish altogether if the T. were absolutely equal. As it is, some slight shades of inequality are allowable. No fifths on the pianoforte or organ are perfect, although in theory they are supposed to be so.

The necessity for temperament arises on account of the imperfection of instruments. No instrument has ever been constructed capable of producing such absolute correctness of tone as the human voice, although stringed are much more accurate than keyed instruments. A singer or violinist with a finely correct ear and intonation will, if left to himself, and if not misguided by a tempered instrument, produce his notes in true relation to each other throughout the most intricate modulations. A habit of mal-intonation in singing is, on the other hand, acquired by learning singing with a pianoforte accompaniment.

One of the earliest writers on T. was Mersenne, who in his *Harmonie Universelle*, published in 1636, divided the octave into fifty-three equal parts. See Woolhouse's *Essay on Musical Intervals* (1835), and article by R. H. M. Bosanquet in Stainer and Barrett's *Dictionary of Musical Terms* (1876).

Tem'perance Movement. The 'Temperance Cause,' so recent in its birth, so rapid in its growth, may fairly claim to be regarded as a typical agency of modern times. With its noble aim—the preservation of the frail and the reduction of human misery—it is a manifestation of active Christianity, equalled perhaps only by the modern extension in the operations of charity. It has an organisation at once concentrated and far-reaching. Vigour and ability are shown in the management of its large corporate bodies and in the enterprise and ceaseless activity of its propaganda. To the support of the educated and the highly stationed it now adds the general sanction of society; it has survived the bitterest attacks of logic and ridicule, and can now count its membership by millions.

Temperance Arguments.—The question of abstinence from intoxicating liquors is of special interest in its physiological and social phases. (1) *Physiological.* That much indulgence in alcoholic drinks causes great injury to the health is now almost as widely admitted as that total abstinence under certain peculiar circumstances is injurious (see INTEMPERANCE). The real point in dispute is whether the regular consumption of a small amount of alcohol by persons of ordinary constitutions and in tolerably good health is beneficial or the reverse. Starting with the assertion that alcohol is not a direct product of nature, the teetotaller argues that by its interfering with the oxygenation of the body's tissues it vitiates the blood and lowers vitality. This, to some extent, is generally admitted, but recent experiment shows that alcohol to the extent of 1½ oz. acts as a highly nutritious food which is easily digested and rapid of production. Professor Hammond, a recent American authority, by experiments upon himself, found that under certain conditions alcohol increases the weight of the body, and maintains the system in a normal state, notwithstanding a diminished dietary. Its effects when taken *plus* sufficient food were, however, disturbance of general health, increased circulation, variable appetite, and physical and mental lassitude. Professor Fraser of Edinburgh University, in a lecture delivered 17th January 1879, says that 1½ oz. of alcohol are equivalent to a fourth part of food in an ordinary mixed diet. Again, the abstainer contends that while alcohol gives a certain stimulus to the nervous system, such stimulus is necessarily followed by relapse, and in order to keep up the stimulus there must be a constant increase in the 'dose.' The answer of the physiologists is that the so-called reaction is not greater than when the effect of ordinary food is exhausted, and against the idea that stimulation requires a regular increase of stimulant, that moderate drinking inevitably tends to excess, an appeal lies to the general experience of civilised society. After arguing that alcohol is a sedative, Dr. Wilkes says its effects on a healthy man would be 'the diminution of the energising wear of the nervous system, especially that employed in emotion and sensation.' In the same strain Dr. T. K. Chambers: 'Alcohol calmly arrests the energies of the nervous system which would fret the tissues to decay. . . . . Now, with years the replacement by nutrition of the tissues is much diminished' (*Diet in Health and Disease*). Sir W. Gull, in evidence given before the Lords' Committee on Intemperance (1878), says he regards it as unnecessary for the young, but 'must consider alcohol in respect of age and climate.' While admitting that out-door workers may take beer beneficially, he denies that intellectual work can be done better with alcohol than without it. Sir James Paget, the distinguished surgeon, thus sums up his unusually long experience: 'My study makes me as sure as I ever would venture to be of any such question, that there is not yet any evidence nearly sufficient to make it probable that a moderate use of alcoholic drinks is generally, or even to many persons, injurious, and that there are sufficient reasons for believing that such a moderate use is on the whole generally beneficial.' This view is supported by Dr. Moxon and Dr. Albert Bernays. On the other hand, Dr. Lauder Brunton, though not objecting to alcohol for those who are past middle age, thinks that a healthy man, eating and sleeping well, is as a rule better without it; while Dr. Murchison, who is more decided, says, 'Its occasional use will do him no harm; its habitual use, even in moderation, may and often does induce disease gradually.' Dr. Radcliffe, a very great authority on nervous diseases, holds that 'as yet there are no trustworthy statistics to show that abstinence is attended with unusual length of life or improvement in health,' while he lays it down as an absolute axiom that 'the majority of adults can take alcohol in some form or other not only with impunity but often with advantage.' The scientific experiments of the late Dr. Anstie and of Dr. Dupré proved that 1½ oz. of absolute alcohol was 'the limit to the food use of that substance in 24 or it may be even 12 hours.' This quantity corresponds, according to Dr. Kidd, to nearly six tablespoonfuls of brandy, to four small glasses of port or sherry, or nearly twice as much of claret, hock, or chablis. Dr. Garrod would allow 'half a bottle of claret' in 24 hours; and there would be about the same amount of alcohol in half an imperial pint of Champagne or Burgundy, in a quarter of a pint of port, sherry, or Madeira, and in three-quarters of a pint of pale ale or stout. Moderation, as defined by the doctors, absolutely forbids the use of alcohol beyond 'the first stage of its action—the quickened state of the nervous system, the livelier mental expression, the gentle warmth of the extremities.' Thus, though the majority of the above opinions (mostly culled from the Symposia in the *Contemporary Review*, Nov. and Dec. 1878) are favourable to temperance as opposed to abstinence, they hold forth not the slightest excuse for indulgence. It would be easier, indeed, for most men to forego alcohol entirely than to restrict themselves to such a modicum as temperance thus defined would allow. Science, at least, seems to condemn what has long been regarded as moderation as in reality excess.—(2) *Social.* The social pleas and counter-pleas, which trench on the one hand on morals, and on the other on politics, may be summarised more briefly. It is urged primarily that drinking is the great cause of all the evils to which the poorer classes are heir. It saps the strength of the artisan or labourer, converts his home into a den of misery, and draws him irresistibly into the current of pauperism and crime. The drunkard is the ready victim of disaster, and retaliates on society in the foulest deeds of violence. His existence imposes on a nation the burden of maintaining a greatly extended system of poorhouses, lunatic asylums, prisons, and police. Not only is his productive labour lost to the nation, which is taxed by the support of such institutions, but his large expenditure on drink places a premium on a business which is an economic anachronism, withdrawing labour as it does from vastly more productive industries, while it occupies 69,000 acres of English soil with hops, and diverts 12,000,000 bushels of the grain supply from its legitimate use, and so increases the price of bread. In 1878 the cost of spirituous liquors consumed in the United Kingdom was estimated at £149,772,610, and, according to Professor Leoni Levi, the working classes contribute, out of every pound paid in taxes to the national exchequer, as much as 13s. 5d. on liquors, as against 3s. 4d. contributed by the middle and upper classes. Nor does this adequately represent the expenditure which the habit of drinking brings upon the class that mainly supports the money-lender, the 'club-man,' and the pawnbroker. Addicted to a costly vice, which rapidly drains their slender means, the poor are notoriously cheated in the quality of liquors by the very publicans they befriend, and are provided with every facility for ruin by easy access to a false system of credit. Regarding the 'drink-curse' as the chief if not the only cause of misery and crime, the abstinence advocate demands the support of those to whom abstinence may not appear a necessary measure of personal precaution: 'If you are fond of wine, you ought to abstain for your own sake; if not, you ought to abstain for the sake of others.' And not pausing at the advocacy of abstinence as a duty to country and humanity, the majority of abstainers look upon legislative restriction as the only proper logical expression of their doctrines. The ordinary counter-pleas are that 'you cannot make people sober by Act of Parliament,' and that it is a fiscal as well as an economic error to regard as lost the large sum expended on Exchequer duties and on the liquor-trade. The misery of the lower classes, it is said, is not due to, but is only augmented by drinking, and any permanent improvement in their condition could only be effected by material and moral reforms. It is affirmed that destitution following a reduction of wages contributes more decidedly than drunkenness to an increase of crime. A prohibitory law would be an unjustifiable interference with liberty, likely to evoke chronic evasion, and certain to produce perpetual strife. It would defeat its own purpose, for abstinence to be valuable must be the result of moral conviction, and men compulsorily deprived of drink would fly to opium or other narcotics. Educate the people, say the opponents of permissive legislation—give them just moral and religious views, substitute for frothy declamation the earnest teaching of science, and the result will be a revolution greater than that which has been effected among the refined and the wealthy.

Legislation.—Accepting the dictum of J. S. Mill, that the liberty of one man ends where it becomes fatal and ruinous to another, the abstainer, with Archbishop Whately, would gladly curtail his liberty if thereby he could restrain another's licence. The legislature admits the exceptionally dangerous nature of the liquor-trade by placing it under strict limitations, why then not suppress it entirely? The amount of drinking is in direct proportion to the number of public-houses, therefore by reducing their number you will diminish intemperance. In the state of Maine, U.S., the liquor traffic was suppressed in 1846, although all

attempts have as yet failed to introduce a similar law in several other states. In Scotland a Sunday-closing law came into operation in 1854, and in Sweden a law (1855) imposing a tax on public-houses proportionate to the amount of spirits sold. Under the Gothenburg license system a responsible commercial company assumes entire control of the liquor trade, paying over to the town treasurer all profits on the drink sold, and these amounted to £35,000 in 1875. This system is only restrictive in so far as the trade is placed under the control of those who are in no way interested in its extension. A local prohibitory or Permissive Act was passed in Canada in 1878, and may be adopted in any county or city on a vote of 25 per cent. of the electors. The British Permissive Bill is designed to enable two-thirds of the ratepayers of a municipal borough or parish to suppress the public-houses within their bounds. It was defeated in 1878 by 288 to 86 votes. The Sunday Closing Act for Ireland (1878) met with determined opposition in the Commons, and was modified so as to exempt Dublin, Cork, Belfast, Limerick, and Waterford from the provisions of early closing. Sir Wilfrid Lawson has intimated (January 1879) that in place of his Permissive Bill he intends to move a resolution that the House gives its opinion in favour of entrusting to the inhabitants of a locality the power of restraining the issue and renewal of licences. The Right Hon. W. E. Forster, at Bradford (Feb. 1), volunteered his support to the modified measure, and his example, it is anticipated, will be followed by the party.

History of the Movement.—For the earliest beginnings as well as the greatest development of temperance organisation we must look to America. What is commonly regarded as the first temperance society was formed at Moreau, Saratoga county, New York, 13th April 1808, by Dr. B. J. Clarke, who expressed alarm at the progress of a vice that threatened to make America 'a nation of drunkards.' This society inflicted penalties of (1) 25 cents on any member who drank spirits or wine except in illness or 'at public dinners;' (2) 50 cents for being intoxicated; and (3) 25 cents for offering drink to others. Its influence was local, but it lived for fourteen years. Various societies, lay and clerical, were subsequently formed, but with little success, till the pamphlets of the Rev. Dr. Edwards arrested the attention of a wider public. On 13th February 1826 the American Temperance Society was organised at Boston, and the Rev. Dr. Hewitt made a series of powerful appeals on its behalf throughout the country. In the same year the *National Philanthropist* was started, and Dr. Lyman Beecher preached his famous 'Six Sermons.' At last fortune began to smile upon the cause, and by 1829 there were 1000 societies and 100,000 members. The same year saw the issue of the *Journal of Humanity*. The first National Temperance Convention was held in 1833, when a general union was formed, and it was reported that the societies numbered 5000, and the membership a million and a quarter. Under President Jackson a law was passed (1834) prohibiting the sale of liquor to the Indians, and in 1835 the Convention of Boston adopted the pledge of total abstinence from wine as well as spirits. Three years later the 'Fifteen-Gallon Law' was passed in Massachusetts prohibiting the sale of spirits in less than that quantity, and this was followed in 1839 by the 'One-Gallon Law' of Mississippi, and the 'Local Option Act' of Illinois. Subsequent restrictions were effected in Michigan, Ohio, &c., while the trade was completely ousted from Maine. The later organisations comprise the orders of Good Samaritans, Rechabites and Good Templars, the Sons of Temperance, &c. In America the cause is advocated in a specially aggressive spirit, and is made a political test by those who regard the licence system as an anomaly.

From America news of the movement early crossed the Atlantic, and in August 1829 a society was formed by the Rev. G. W. Carr at New Ross in Wexford, and another at Belfast by Dr. Edgar and others. Before a year had expired Ireland had 60 societies and 3500 members. In October 1829 the first Scottish society was organised at Greenock by Mr. John Dunlop, aided by Mr. William Collins, editor and publisher of *The Temperance Record* (1830-35). The Glasgow and West of Scotland Society, while forbidding ardent spirits, allowed the moderate use of other liquors. Its activity was remarkable, for by 1830 it had 5072 members in Glasgow alone, and had circulated 425,300 tracts and 20,250 pamphlets. A more stringent application of the temperance principle was introduced by Mr. John Davie, who in 1830 formed a society at Dunfermline pledged to abstinence from all liquors, 'small-beer excepted, and wine on sacramental occasions.' This was the precursor of the total abstinence societies which sprang up throughout the country. In England the movement, inaugurated by Mr. Henry Forbes at Bradford in February 1830, spread to Farrington in April, and to Manchester in May, and by the end of the year there were 30 societies with 10,000 members. The British and Foreign T. Society, formed in June 1831, was headed by the Bishop of London, and comprised several members of Parliament and various dignitaries. Its pledge was to abstain from distilled spirits and 'to discountenance the causes and practice of intemperance.' For many years as the leading society in England it represented the highest intelligence of the cause. At Preston in 1832 Mr. Joseph Livesey and others started the first English *teetotal* society. *Teetotal* is said to be a Lancashire accentuation of total; but its origin is also assigned to the climax of a stuttering philippic by one 'Dicky Turner,' when he declared, 'I'll be reet down tee-tee-total for ever and ever.' Founded in conformity with the stricter principle (1835), the British Teetotal T. Society was merged in 1836 in the New British and Foreign Society. The question of long and short pledges raised bitter discussion in England, but in the end the long pledge conquered everywhere. Meantime Father Mathew (q. v.) had enrolled in Ireland's Great National Total Abstinence Society as many as 1,800,000 members in two years. Among the various organisations that, with certain modifications of creed, carry on the T. crusade in Great Britain the chief are the British T. League, established 1835, with 1900 subscribers to the funds (organ, *British T. Advocate*); Western T. League, 1837, with 414 affiliated societies in 1878 (*The Herald*); National T. League, 1854, with an income (1878) of £4562, and branches on board 202 ships of the Royal Navy and in many regiments, its Indian Soldiers' Association having 9746 members (*Record* weekly, and *Medical Journal* quarterly); Midland League, 1856; North of England League, 1858, with 175 affiliated societies; Scottish League, 1844, with an income, 1878, of £7456, 10,569 members and 402 affiliated societies (*Journal* and *Adviser*); Glasgow Abstainers' Union, 1854; and United T. Association, 1873. There are several juvenile organisations, of which the chief is the United Kingdom Band of Hope Union, with 2305 unions in England, 98 in Scotland, and 133 in Ireland; its organ is the *Chronicle* (since 1877). This body held, in 1878, 2870 meetings, attended by 270,328 persons, and distributed 453,864 publications. Besides the influential Church of England T. Society, re-formed in 1874, there are distinct branches representing the Congregationalists, Methodists, Friends, and Roman Catholics. The principal political organisation is the United Kingdom Alliance, established in 1853, 'to procure the total and immediate legislative suppression of the traffic in intoxicating liquors as beverages.' The Independent Order of Good Templars (I.O.G.T.), the latest development of the cause, originated in New York in 1851, and reached England in 1868, Scotland in 1869, and Ireland in 1870. It is professedly a religious body, with an evangelical ritual, and takes its name from a fancied resemblance between its object and that of the Knights Templars, who warred with the Saracens in defence of the Holy Sepulchre. Making free use of social as well as strictly missionary means, it is characterised by the zeal of its members, the frequency of its meetings, as well as by a showy ceremonial, a lavish use of high-sounding titles, and a system of secret signs analogous to that of the Freemasons. The movement has spread with unprecedented rapidity, and already (1879) numbers in England and Wales 126,000 adults and 50,000 juveniles, and in Scotland 55,000 adults and 20,000 juveniles. In 1876 a split occurred between the American and European lodges on the question of the admission of coloured people, and the Order has since been divided into two nearly equal sections, the membership of both together amounting to some 700,000 adults. There are lodges in the African colonies, in Australia, India, and even in Japan and China. The organ in England is the *Watchword*. See the Rev. G. Gladstone's *Good Templarism* (Glasg. 1872), and the Hon. S. B. Chase's *Manual* (Edin. 1872).

A T. and General Life Assurance Co., London, founded in 1840, has issued 60,000 policies, and with an accumulated capital of £2,000,000, distributed a bonus of £348,458 in 1876. Its tables show a mortality in the five years 1871-75 of 723 among temperance and 1266 among general assurers. The London T. Hospital, founded in 1873, has been a singularly successful experiment in the non-alcoholic treatment of disease.

For information as to the whole T. M., see Graham's *Annual Guide* (Lond.), Evans' *Annual* (Lond.), *The Centennial Temperance Volume* (Philadel. 1877), the Evidence of the House of Lords' Committee on Intemperance (4 vols. 1878), and its Report, forthcoming; and Dr. Richardson's *Total Abstinence* (1879).

Tem'perature of a body is defined by Clerk Maxwell as 'its thermal state considered with reference to its power of communicating heat to other bodies.' If two bodies in thermal communication are observed the one to lose and the other to gain heat, the former is at a higher temperature than the latter; and if no such transfer of heat takes place the bodies are at the same T. The ordinary method for measuring T. is described under THERMOMETER. As a factor in meteorological phenomena, the careful measurement of T. is of the greatest importance; and the T. of any place depends first and foremost upon its position on the earth's surface relatively to the sun, which is our great storehouse of heat. The heat which is constantly being conducted from the earth's centre outwards and radiated from the earth's surface into surrounding space has little climatic influence except in limiting the minimum T. possible upon our globe in natural circumstances. The lowest natural T. ever observed was recorded by Hansteen in 55° N. lat., who observed it as low as 68°.3 C. below zero. Probably lower temperatures do exist in higher and unattainable latitudes; but at such low temperatures mercury freezes, and the spirit-of-wine thermometer is hardly trustworthy. The lowest artificial T. has been obtained by Cailletet when he solidified hydrogen by its own expansion (1878). To measure such a low T. is hopeless. The highest terrestrial T. with which we are acquainted is that of the electric light, which Becquerel estimates at 2070° C. Still higher is the T. of the sun, which, however, is probably far inferior to that of some of the brighter stars. Estimates of the T. of the space through which our system is passing have been made by Fourier, Pouillet, Hopkins, and others. The data, however, are insufficient, as proved by the discrepancy of their results; and not till we have measured the rate of radiation of the sun and planets, not to speak of other suns, can we hope to get even an approximation to the T. of space. The T. is probably very low, since there is evidence of very small absorptive power in circumplanetary space for radiant energy.

Tem'perature of the Body. The terms *cold-blooded* and *warm-blooded* animals serve roughly to indicate, the former, those animals which possess a temperature little raised above that of the surrounding medium; the latter, those with one considerably higher. Fishes, frogs, and reptiles are cold-blooded animals, whilst birds and quadrupeds are warm-blooded. Heat is produced through the combination of the oxygen of the atmosphere with the carbon and hydrogen of the blood and tissues. A much larger quantity of carbon and hydrogen is added to the blood from the food than the ordinary nutrition of the body demands; and the oxygen inhaled from the atmosphere, uniting with these elements, produces heat, carbonic acid, and water—the latter products representing the ashes of the bodily fire. Thus the temperature of the living body depends on chemical change. It is produced by the oxidation of combustible materials derived from the tissues and from the blood. The quantity of carbon and hydrogen which in any given period unite with oxygen in the body, may be accounted for by the quantity of heat generated in the same period. The temperature of an animal must thus be proportionate to its respiration, and to the activity and frequency of its breathing movements.

The circumstances which influence the temperature of the human body in health are very varied. The normal temperature of the internal parts varies from 98·5 to 99·5. The average temperature of the armpit is 98·6. In infant life the temperature is about 1° F. above that of the adult; and the temperature of old age resembles that of infancy. The temperature of the female slightly exceeds that of the male; and the temperature of the human body falls to its lowest level in the early morning. The *influence of disease* on temperature is very marked. In cases of fever and all diseases accompanied by increased oxidation of tissue and by abnormal tissue-waste, the temperature may rise to an almost unprecedented height. In typhus fever and pneumonia the temperature may rise to 106° F. or 107° F. Cases of malignant fever have been recorded in which the temperature of the armpit attained 111° F., and Wunderlich has placed a case of idiopathic tetanus on record in which the temperature was 112·5° F. at the time of death. On the side of *lowness* of temperature may be mentioned cases of *morbus cæruleus*, in which the blood is imperfectly ærated, when the temperature may sink to 77·5° F. In Asiatic cholera the mouth-temperature may be as low as 77° or 79° F., and Dr. Gee records a case of tubercular meningitis in which the temperature of the rectum remained for some hours at 79·4° F.

Tem'pering, in connection with metals, is a process similar to Annealing (q. v.), applied to metals and other substances. T. results in a molecular change in the structure of the body operated upon, and it is effected by a slow cooling of the substance from a heat varying according to the 'temper' desired (see STEEL). T. is a term almost exclusively employed in connection with iron and steel, cast iron being tempered in the same way as steel, and the production of what are now extensively used as 'malleable castings' being governed by a process partly of T. and partly of decarburation.

Tem'plars, Good. See TEMPERANCE MOVEMENT.

Tem'plars, Knights (*fratres milites templi*), one of the most remarkable of the orders of knights that flourished during the Middle Ages. Their origin is connected with the crusades. When a Christian kingdom was founded at Jerusalem, the enthusiasm of Western Christendom for the Holy Land reached its highest point, and crowds of pilgrims resorted thither. In 1119 several knights—of whom Hugo of Payens and Gottfried of Omer were the chief—formed themselves into a society to afford pilgrims help on their dangerous journey, and to keep the way clear of robbers and infidels. They received as dwelling a part of the Temple from Baldwin II., King of Jerusalem, and hence they were called poor knights, or brothers of the Temple. Their services were found of great value; they rose in the public estimation, and their number rapidly increased. At the Council of Troyes in 1128 Pope Honorius II. formally ratified the constitution of the order, confirmed Hugo of Payens in his post as grandmaster, and appointed as their distinguishing dress a white mantle, to which Eugenius III. added a simple red cross. The impression of their great seal was two knights on one horse, which signified either the original poverty of the order, or the mutual helpfulness of its members. In battle they displayed a black and white banner with the inscription 'Non nobis, Domine, non nobis, sed nomini tuo da gloriam.' After the council, Hugo with several companions travelled about on a recruiting expedition among the various courts of Europe. The grandmaster returned to the East with 300 knights, and this was only the beginning of a long course of prosperity and power, for the Templar was the embodiment of the two strongest desires of the Middle Ages —the desire for military renown and for a monk's life. The monk and the knight were the ideals of the period, and the Templar was both. As the order increased, the original and simple constitution drawn by Bernard of Clairvaux gradually became obsolete. Between 1247-66 the whole rules were revised and promulgated anew in an improved form. According to these, the K. T. consisted of three orders:—1. The knights, who were all of noble family. 2. The *fratres servientes* ('serving brothers'), who were from the citizen class, and were either (*a*) *armigeri*, or brothers-in-arms, who fought, voted, and were even eligible for some of the lower offices of the order; and the (*b*) *famuli*, or servants, who were craftsmen and performers of menial duties. 3. The *affiliati*, men in all conditions of life who attached themselves to the Templars in order to share their privileges. 4. A small number of dignified priests and chaplains who act as spiritual advisers to the order. The officers of the Templars were (1) the Grandmaster, who had the rank of a prince, (2) the Seneschal, (3) Marshal, (4) the Grand Preceptor, (5) the Draperer, (6) the Turkopolier, (7) the General Visitant. The affairs of the order in peace and war were divided among the officers, all of whom, except the last, were elected for life. The K. T. had numerous temporal and spiritual privileges, and in 150 years from their institution the order consisted of 20,000 knights, and had 9000 various kinds of possession in different parts of the East and West. When Jerusalem was retaken by the infidels they removed to Cyprus, and when this island also was lost they established their headquarters in France. But their wealth and luxury had raised up many enemies against them. Other orders were jealous of them, and the dignified clergy, with whose power their rights interfered, hated them. At last Philip II. of France, afraid of their power and

greedy of their wealth, resolved upon their suppression. He forced Clement IV., who then filled the Papal See, to assent to his plan, and on the 13th October 1306 all the K. T. who could be found in France were seized. It is unnecessary to detail the successive steps by which the order was fully suppressed; suffice it to say, that all the proceedings were characterised by the blackest injustice and the foulest cruelty, which may be said to have culminated in the murder of Jacques de Molay, the last grandmaster of the order, who perished at the stake, on an island in the Seine, 11th March 1314. The execution took place simply in virtue of the king's order, who was enraged that the grandmaster withdrew some false confession which the rack had extorted from him. The Knights of St. John obtained some of the property of the order, but the greater part fell to the share of the monarchs in whose kingdoms the Templars had flourished. See *Hist. Critique et Apologetique des Chevaliers de St. Jean de Jerusalem dits Templiers*, by Le R. P. M. J. (2 vols. Par. 1789); Wilcke, *Geschichte des Tempelherren-ordens* (2 vols. Leip. 1826-35; 2d ed. Halle, 1860); Haremann, *Gesch. des Ausgangs des Tempelherren-ordens* (Stuttg. 1846). In English, Addison's *Hist. of the Templars* (Lond. 1842); A. O. Haye's *Persecution of the Templars* (Edin. 1865).

Tem'plate, or **Tem'plet** (Lat. *templum*, 'a portion or piece cut off,' from Gr. *temno*, 'I cut'), a pattern in thin board or metal used by masons and bricklayers as a guide in forming ornaments, and by machinists, &c., in shaping teeth of wheels and other objects.

Tem'ple. The first T. at Jerusalem was erected by Solomon. His father David, who had intended building one, but had been prevented by the prophet Nathan (2 Sam. vii. 1-17; 1 Chron. xvii. 1-14, xxviii.), had still made certain preparations for the work by laying up treasure (2 Sam. viii. 7-12; *cf.* 1 Kings vii. 51) and collecting materials (1 Kings v.; 1 Chron. xxii.). The site was Mount Moriah (see JERUSALEM), the top of which, however, was insufficient, and had to be enlarged by masonry on the precipitous sides of the hill (Jos. *Bell. Jud.* v. 5). The building was begun four years after the death of David (about B.C. 1012; *cf.* 1 Kings vi. 1; 2 Chron. iii. 2). The stone and timber employed were brought from Phœnicia under a contract made by Solomon with Hiram, king of Tyre, who also supplied a large number of workmen for dressing the materials. The dimensions of the T. were exactly double those of the Tabernacle (q. v.), on the model of which it was constructed, with the exception of the height, which was 30 cubits, or three times that of the tabernacle. Only a third part of this would be the height of the sloping roof; at any rate, the inside of the holy of holies was a cube of 20 cubits (1 Kings vi. 20). The inside of the stone walls was lined with cedar-wood, which again was overlaid with gold. On the outside of the walls were a number of chambers, in three stories, which served as houses for the priests, magazines, bake-houses, and workshops (1 Kings vi. 5-10).

The first T. was destroyed by Nebuchadnezzar (B.C. 588), and a second was built on the same site by the Jews on their return from the Babylonian captivity (B.C. 536, Ezra i., vi.; begun 534, interrupted through the Samaritans till 520, and finished 516; Ezra v., vi. *cf.* Hagai i. 15). Pillaged and desecrated by Antiochus Epiphanes (B.C. 170), it afterwards became so desolate that it was overgrown with shrubs (1 Macc. iv. 38; 2 Macc. vi. 4); but it was purified and re-dedicated by Judas Maccabæus (B.C. 165). It was taken by Pompey, B.C. 63 (Jos. *Ant.* xiv. 4), and stormed and partially destroyed by Herod the Great, B.C. 37.

The third T. was that built by Herod, which was an entirely new structure, and the largest and most magnificent of the three (*cf.* Mark xiii. 1, 2). Begun about B.C. 20, the T. itself was finished in about a year and a half, and the outer buildings in eight years, although there were building operations carried on under Herod's successors (Jos. *Ant.* xv. 11; *Bell. Jud.* v. 5; *cf.* John ii. 20). This T. was completely destroyed at the capture of Jerusalem by the Romans, A.D. 70. A splendid mosque was built on the site by the Calif Omar after the conquest of Jerusalem by the Saracens (636). See Fergusson's *Temples of the Jews and other Buildings in the Haram Area at Jerusalem* (Lond. 1878).

Tem'ple. See INNS OF COURT.

Tem'ple, Frederick, born 30th November 1821, from Tiverton grammar-school gained a Balliol scholarship, and having taken a double first (1842), was elected fellow and mathematical tutor. Ordained in 1846, he became Principal of the Training College at Kneller Hall near Twickenham (1848-55), and head master of Rugby (1858-69). A Liberal in politics, a 'Broad Churchman' in theology, T. wrote one of the famous *Essays and Reviews* (1860), that on the 'Education of the World,' and his appointment to the see of Exeter in 1869 was met by strong though unavailing opposition. He has published *Sermons Preached in Rugby Chapel* (1858-60; new ed. Lond. 1867).

Tem'ple, Sir William, descendant of a Leicestershire family dating from the 13th c., proceeded from Eton to King's College, Cambridge, and early in Elizabeth's reign became master of Lincoln free school. A Latin essay (1581), dedicated to Sir Philip Sidney, brought him under the notice of that peerless knight, who made him his secretary, and dying in his arms at Arnheim, commended him to the Earl of Essex. Him T. followed to Ireland, where he rose to be provost of Trinity College, Dublin (1609), its representative in the Irish Parliament (1613), a knight and master in Chancery, and there he died in 1626.—His son, **Sir John**, born in London and bred in Dublin, was knighted (1640), under the Parliament became a commissioner in Munster, and after the Restoration a privy councillor, treasurer, and master of the rolls, and died in 1677. His *History of the Irish Rebellion* (1646, 3d ed. 1812) is truthful and scholarly, though written from an ultra-English point of view.—**Sir William T.**, son of the preceding, born in London in 1628, was educated at Penshurst, at Bishop Stortford, and under Cudworth at Emmanuel College, Cambridge. He then travelled in France, the Netherlands, and Germany, and marrying (1654), settled in Ireland. As member for Carlow (1661) he won the favour of Ormond, the lord-lieutenant, and introduced by him to Arlington, was sent to negotiate with the Bishop of Münster (1665). His success brought him a baronetcy and the post of resident at Brussels, and in 1668 he established his diplomatic fame by concluding with Holland and Sweden the celebrated Triple Alliance. At the Hague, where he now became ambassador, he made the friendship of De Witt and the Prince of Orange (whose marriage with Mary was T.'s work), and here he remained till 1670, when French and Cabal intrigues drove him from office. Withdrawing to Sheen, he gave himself up to gardening and writing his *Observations on the United Provinces* (1672), but in 1673 was summoned from his retreat to terminate the second Dutch war, resume his embassy, and carry through the negotiations that ended, but little to his liking, in the Peace of Nimeguen (1679). He shrank from the stormiest scenes of Charles's reign, refusing the proffered secretaryship of state, and on his scheme for a privy council falling through, abandoned politics for ever. At his Surrey seat, Moor Park, he passed his last years in epicurean ease, interrupted only by visits from William III. He died, January 27, 1699, leaving a younger brother, the father of the first Viscount Palmerston. Sir William's posthumous works were edited by Swift (q. v.), and a complete edition appeared at London (4 vols. 1814). See his Life by Courtenay (2 vols. 1836) and Macaulay's review of it, also Emmerton's *Sir W. T. und die Tripleallianz* (Berl. 1877).

Templemore' (Ir. Gael. 'the great temple' or 'church'), a town of Tipperary, Ireland, on the Suir, and a station on the Great Southern and Western Railway, 20 miles N. of Cashel and 80 from Dublin. T. has some trade in butter, cattle, &c. In the vicinity is the Priory, the mansion of Sir J. C. Carden, Bart., the beautiful grounds of which attract numerous visitors. Pop. (1871) 3443.

Tem'po, in music, the Italian word used to express time or the degree of rapidity at which a piece is to be played. The pace is usually indicated by certain words, such as *Grave* (very slow), *Lento* (slow), *Adagio* or *Largo* (leisurely), *Andante* (moving or walking pace), *Allegro* (gay or quick), *Presto* (rapid), *Prestissimo* (very rapid), &c. These terms are intensified by such words as *molto* (very), and modified by words like *non troppo* (not much). *Accelerando* denotes an increase of time, *Rallentando*, a slackening; *A Tempo*, a return to the original time. The exact length of each note may be still more precisely defined by a sign placed at the beginning of a work, such as ♩ = 124, which means that when the regulator of the metronome is placed at 124, each beat of the pendulum equals a crotchet, giving 124 crotchets to the minute. The word is most exten-

sively used in music, the following being a few examples:—*T. di ballo*, dance time; *T. di capella*, church-music time; *T. comodo*, easy time; *T. di marcia*, marching time; *T. primo*, first or original time; *T. reggiato*, time regulated to suit a solo performer; *T. rubato*, time varied for the sake of expression, what is taken from one note being given to another, or the pace being accelerated in one place and retarded in another; *T. di valse*, waltzing time.

Tena'city is the property which all bodies, but especially metals, possess of resisting a breaking stress. See COHESION and STRENGTH OF MATERIALS.

Tenaille', in fortification, is an outwork placed in front of the curtain, the postern and escarps of which it prevents being breached. See FORTIFICATION.

Ten'ancy at Will means that the tenancy is terminable at any time, by either party, under equitable circumstances. A tenant must be allowed reasonable time to remove, and to reap the fruits of crops which he has sown.

Ten'ancy in Common. See COMMON TENANCY.

Ten'ant for Life. The fruits of an estate may legally be given to any one, conditionally that the interest cease on the death of some one else; or, that on the grantee's own death the interest shall go to an individual, or in a manner specified. The immediate tenant is called in law a T. for L. Where no conditions as to the treatment of the subject are specified by the deed, the T. for L. will not be allowed to do any act tending materially to lessen its value or amenity. In Scotland a T. for L. is called a liferenter. See LIFERENT (q. v.).

Ten'ant in Fee Simple. See FEE SIMPLE.

Tenant-Right' is a term not unknown to English law, but has acquired prominence chiefly in connection with Ireland. According to the custom of Ulster, the tenant of a farm had (or claimed) a right of occupancy not subject to removal; fixity of rent; and also, in the event of his giving up his occupancy, a right to compensation for improvements effected. The origin of T.-R. is undoubtedly to be found in the old Celtic tenure of land, according to which ownership was vested not in the individual but in the tribe or clan. Practically throughout the North of Ireland this Ulster custom was conceded, though its non-recognition by the law was the cause of much angry and bitter disputation between landlords and tenants in individual cases. In other parts of Ireland, where the right had never been conceded by proprietors, the Celtic sentiment was equally strong; ejection from a holding was regarded as the worst of outrages, provoked the bitterest animosity, and was frequently followed by the assassination of the landlord or his agent. In 1870 the Gladstone ministry passed the 'Landlord and Tenant Act,' which gave to the Ulster custom and similar customs in Ireland the force of law, and where such did not exist made adequate provision for securing the rights of outgoing tenants. In Scotland and the North of England, where farms are let on leases of such length that tenants are supposed to be able to repay themselves for the improvements they make on the land, the question of T.-R. has not yet taken any practical shape, and perhaps never may.

Tenass'erim, a division of British Burmah, S. of Pegu, forming a strip of coast-line, intersected by rivers and fringed with islands, between the mountains of Siam and the Bay of Bengal. Area, 46,730 sq. miles; pop. (1872) 600,727. The inhabitants include the Burmese proper and the exiled Peguese, who are both Buddhists, and the hill-tribe of Karens (q. v.), of whom many have become Christians. This tract was only conquered from Siam in the middle of the last century by the founder of the present Burmese dynasty. In 1824, during the first Burmese war, it was occupied by the British, and formally made over to them by the treaty of 1826. It contains the fertile district of Amherst, with the flourishing port of Moulmein (q. v.), and is reckoned to possess the most healthy climate within the tropics. The products are rice, timber (especially teak and sappan), caoutchouc, iron, and tin. Coal has been found. Other towns are Mergui (q. v.), Tavoy (q. v.), and T., which is now of no importance.

Ten'by, a Pembrokeshire watering-place, on Caermarthen Bay, 9½ miles E. of Pembroke by rail. One side of its old town wall stands almost perfect, but the ruins crowning the peninsular Castle Hill are inconsiderable. Near them a colossal marble statue of the Prince Consort was erected (1865). The Church of St. Mary, with a spire 152 feet high, has been restored, and other buildings are the market-house (1829), fishmarket (1847), assembly rooms, baths, St. Catherine's Fort (1868), &c. T. publishes two weekly papers, and with Pembroke, Milford, and Winton returns one member to Parliament. Pop. (1871) 3996. T. (Cym. *Din-bach y Pysgod*, 'little fortress of fishes') was one of the Flemish colonies planted by Henry I. in Pembrokeshire (q. v.) See Mrs. Hall's *History of T.* (1864).

Tench (*Tinca vulgaris*), a species of Teleostean fishes, common in ponds and lakes, and attaining a length of from 10 to 12 inches. It is very sluggish, apparently inhabiting bottom-waters, and feeding on refuse vegetable matter. The colour is generally a greenish-olive above, a light tint predominating below. The flesh is somewhat coarse and insipid. The T. spawns in May and June. It is very tenacious of life, and may be conveyed in damp weeds for long distances. The T. is usually placed in ponds with Carp (q. v.).

Ten'da, Col de, a pass in the Maritime Alps, between the Italian province of Cuneo and the French department of Alpes-Maritimes, has a height of 6162 feet.

Ten'der of Money is, in many cases, a bar to legal action. A tender of bank-notes is good, unless objected to at the time. So is a tender of foreign coin made current by proclamation. It is sufficient if the tender be to an authorised agent, but a bailiff who makes out a distress cannot delegate his authority, therefore a tender to *his* agent is insufficient. A tender to one of several joint-creditors is a tender to all. In an action for damage, if the defendant make a tender which the plaintiff refuses, should the jury award a sum in excess of the tender, costs will be awarded to the plaintiff, otherwise to the defendant.

Ten'dons, the scientific name of the 'sinews,' or stout fibrous bands which bind and attach muscles to bones. They consist of bundles of white fibrous tissue fibres, are capable of resisting a very considerable strain, and serve by their firm attachment to bones to increase the contractile power of the muscles. Examples are the T. of the *extensor muscles* of the fingers, and the *Tendo Achillis*, which is inserted into the *os calcis* or heel-bone, and which serves as the attached point of the great muscles of the calf.

Diseases and Injuries of T.—T. and their sheaths are not unfrequently inflamed, more especially the sheaths of the long T. of the forearm, after excessive exercise, forming a long, sausage-shaped swelling, and accompanied with considerable pain, and a peculiar creaking sensation when the muscle acts, 'ténosinite crépitante' of French authors. The treatment consists in rest to the parts, and the local application of iodine. Rupture, the result of sudden and violent exertion, sometimes takes place, the usual seat being at the juncture of the muscle and tendon; but sometimes the T. are ruptured, especially the tendo Achilis, the flexor T. of the wrist, the T. of the rectus femoris, and the triceps humeri. The main point of treatment consists in keeping the injured part in a state of perfect rest and relaxation, so that the severed ends may be in close approximation until complete union has taken place. One of the most important diseases of T. is Whitlow (q. v.). For the process of union in divided T. see Adams *On the Reparative Process in Human T. after Division*, and Holmes' *System of Surgery*, vol. iii.

Ten'edos (Turk. *Bogdsha-Adassi*), a Turkish island in the Ægean, 17 miles E. of the Dardanelles, is 5 miles long by 2 broad, and is famed for its exquisite wine. Pop. 2000, partly Greeks.

Teneriffe' ('white mountain'), an island of the Canaries (q.v.), has an area of 1000 sq. miles, and its chief town, Santa Cruz (q. v.), is also the capital of the group. The celebrated Peak of T., locally called the Pico de Teyde, is a remarkable conical mountain, 12,182 feet high, with two summits, the higher of which is called El Piton, and is the peak proper. The other, called Chahorra, is 9880 feet high, and is connected with El Piton by a sharp ridge. Both rise from a circular plain 7000 feet high, 8 miles in diameter, composed of pumice-stone and blocks of lava, and surmounted by a ridge resembling the ramparts of a fortress. Snow lies on El Piton for four months of the year. The view

from the top is magnificent, when not interrupted by a thick layer of cloud which frequently skirts the mountain at a height of 3500–4500 feet, and the peak is visible 100 miles off. The craters on the summits of El Piton and Chahorra appear to be extinct, but smoke and sulphurous vapours constantly issue from vents lower down, and an eruption from orifices on the flanks of Chahorra took place in 1798.

Tenes, an Algerian seaport, 100 miles W. of Algiers. It has an artificial harbour, which is rather exposed to W. winds. T. formerly enjoyed a large export and transit trade, but this has been diverted since the construction of the Algiers-Oran railway, and T. is now steadily declining. Pop. (1877) 3000.

Tenes'mus (Gr. *teinō*, 'I strain') is the term employed in medicine to designate a continual inclination to void the contents of the bowels when no fœcal matter is present in the rectum, the straining being excited by some adjacent source of irritation of the muscles of the *sphincter ani*, produced generally by acrimonious substances. T. is a frequent symptom of dysentery, calculus, irritation of the bladder, stricture, &c. The treatment consists in the removal of the cause; and the local irritation may be relieved by the administration of an opiate enema, or a suppository containing morphia.

Ten'iers, David, 'the Elder,' a Flemish painter, was born at Antwerp in 1582, received his first artistic education from his father, Julian T., and in 1606 entered the famous guild of St. Luke in his native city. The statement that he was a pupil of Rubens is not borne out by his works, but he spent a considerable time at Rome, and there came under the influence of Adam Elzheimer. Familiar scenes from country life are his favourite themes, and when he ventures on great historical scenes he makes little allowance in his treatment for the difference of subject. He died at Antwerp in 1649.—**David T.**, 'the Younger,' son of the preceding, was born at Antwerp in 1610. About 1632–33 his father's influence procured him admission to the guild of St. Luke; but his first efforts appear to have met with indifferent success. By-and-by, however, his merit was recognised; he found a powerful patron in Leopold, Archduke of Austria, who appointed him his court painter and inspector of his gallery; the King of Spain became his ardent admirer; and Queen Christina of Sweden, the Prince of Orange, and lesser dignitaries without number, sought the favour of his pencil. His latter years were spent in his pleasant country seat of De Dry Toren, near Lerck. He died at Brussels, 25th April 1690. T. ranks as one of the very greatest of genre painters; but also produced historical works and landscapes. He painted in all about 1000 works. He has left behind him an immense number of works. Nowhere, perhaps, is he better represented than in the collections of Madrid, Antwerp, Paris, and St. Petersburg. M. Alphonse Wauters in *L'Art* 1877 suggests that there is probably a third David T., son of the second, who signs himself D. T., junior, and that his productions are not unfrequently confounded with those of his father.

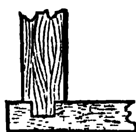
Tenn'ant, William, LL.D., a Scottish poet and linguist, was born at Anstruther, in Fife, May 15, 1784. Having studied two years at St. Andrew's University, and finding little satisfaction in his brother's business as a corn-merchant, he became a schoolmaster, first at Denino, near St. Andrews, next at Lasswade, near Edinburgh, and finally in the Academy at Dollar, where he remained fifteen years. In 1834 he was appointed Professor of Oriental Languages in the St. Andrews University, and he continued to hold the post till his death, October 15, 1848. T. is best remembered as the author of the humorous poem *Anster Fair* (1st ed. 1812), written in the then forgotten measure of the *ottava rima*. The rest of his poetical works—*Papistry Stormed; The Thane of Fife; Cardinal Beaton, a Tragedy; John Balliol, a Historical Drama; Hebrew Dramas*, &c.—were all more or less failures. He also published a *Syriac and Hebrew Grammar* (1840). See M. F. Conolly, *Life of W. T.* (1861).

Tenn'ent, Sir James Emerson, son of William Emerson, a rich Belfast merchant, was born at Belfast, 7th April 1794, graduated B.A. at Trinity College, and travelled through Europe and the Levant (1824–25). In Greece he met Byron, whom he emulated in enthusiasm for the Hellenic liberation. He wrote *A Picture of Greece* (1826); *Letters from the Ægean* (2 vols. 1829), and a *History of Modern Greece* (2 vols. 1830). In 1831 he was called to the bar, but never practised, as in the same year he married the daughter and heiress of Mr. W. Tennent, a rich Belfast banker, whose name and arms he assumed. Returned to Parliament by Belfast in 1832, he at first supported Lord Grey, but withdrawing from the Whigs with Lord Stanley and Sir James Graham in the Derby 'dilly,' he ever after followed Peel as a Liberal-Conservative. He was secretary to the Indian Board, 1841–45, to the Colonial Government of Ceylon, 1845–50, to the Poor-Law Board, 1852, and to the Board of Trade, 1852–67. On his retirement from official life in 1867 he was rewarded with a baronetcy. He died in London, 6th March 1869. His later works are *Travels in Belgium* (1841); *Christianity in Ceylon* (1850); *Wine, its Use and Taxation* (1856); *Ceylon, Physical, Historical, and Topographical* (2 vols. 1859); *Natural History of Ceylon* (1860); *The Story of the Guns* (1864), and *The Wild Elephant in Ceylon* (1867). The large general work on Ceylon, still the standard account of the island, went through three editions in 1859, and reached a fifth in 1860.

Tennessee', one of the United States of N. America, stretching E. and W. between the Appalachians and the Mississippi, and bounded N. by Kentucky and S. by Mississippi, Alabama, and Georgia. Area, 46,600 sq. miles, or 29,184,000 acres; pop. (1870) 1,258,520, of whom 936,119 were white and 322,331 coloured. T. is bordered on the E. by the Unaka Mountains, a portion of the Appalachians, and several other ranges parallel to these cross it from N. to S., the most westerly being the Cumberland Mountains. Between these ranges are fertile valleys, the chief being the valley of East T., immediately E. of the Cumberland Mountains. W. of that range the surface is crossed by several hill-ranges of moderate elevation to T. River, beyond which a vast plain stretches to the Mississippi. The geology of T. is very varied. In the E. are Metamorphic and Silurian formations, of which the Unaka Mountains are composed. Coal-measures extend over the Cumberland Mountains, while in the W. the formations are mostly Tertiary and Recent. The navigable rivers of T. are the Mississippi on its W. boundary, the Cumberland (q. v.), and T. (q. v.). In 1870, 19,581,214 acres of land were in farms, of which the value was £43,000,000, while that of the farm productions was £17,000,000. In 1874 T. produced 11,121,000 bushels of wheat (valued at £2,357,000), 238,000 of rye, 31,953,000 of Indian-corn, 3,816,000 of oats, 1,124,000 of Irish potatoes, 1,205,000 of sweet potatoes, 300,000 bales of cotton, and 114,300 tons of hay. T. is the third State in the Union for tobacco, of which 3,500,000 lbs. were raised in 1875. In that year it contained 318,000 horses, 107,300 mules and asses, 2,767,800 cattle, 325,500 sheep, and 1,193,500 swine. The 5317 factories in the State in 1870 were driven by 732 steam-engines and 1340 water-wheels, having an aggregate of 37,983 horse-power, and employing 19,412 hands. There were 216 flouring-mills, 349 saw-mills, 65 furnaces, 395 tanneries, 28 cotton-mills, 220 wheel and carriage works. In 1876 there were 1649 miles of railway opened. The chief town of T. is Nashville (q. v.). Knoxville (q. v.) and Memphis (q. v.) are the next most important. T. was admitted to the Union in 1796, and in the civil war sided with the Confederacy.

Tennessee', a river of T. State formed by the confluence of the Holston and French rivers at Kingston, in East T. It flows S. into Alabama, then W. through that State, and lastly N. through the State of T. into Kentucky, where it joins the Ohio. The T. is 800 miles long, drains 41,000 sq. miles, and is navigable up to Birchwood. There are 1100 miles of navigable waterway on the T. and its tributaries. Rapids interrupt the navigation 280 miles above its mouth.

Tenn'iel, John, an English artist, was born in London in 1820, and, while a mere boy, exhibited at the Gallery of British Artists in Suffolk Street. Self-taught in art, he was chosen in a competition to paint a fresco in Westminster Palace in 1845, and in 1851 was regularly engaged as a draughtsman for *Punch*, in which periodical for many years his bold, graceful cartoons have been a characteristic feature. He has also illustrated 'Æsop's Fables,' 'The Ingoldsby Legends,' 'Alice in Wonderland,' &c.



Tenn'is, a ball game played in a specially constructed court by two opponents who keep the ball continually in motion by striking it with a racket. Games of ball have a very remote

origin. The Greeks indulged in them, and considered Aristonicus worthy of a statue for his skilful play. Throughout the dark ages the ancient game seems to have undergone various modifications in different European countries. T. is supposed, from the terms still used in the game, to have originated in France prior to the 15th c. It became very fashionable in England during Charles II.'s reign, but is now superseded by rackets, for which there are courts at the universities and public schools. A racket-court measures 120 feet long and 45 broad, and is divided by a net across the centre into the *dedans* and *hazard* sides, in each of which a player is stationed. Each side is subdivided into *first gallery*, *door*, *second gallery*, and *last gallery;* on the dedans side, the last gallery has six compartments called *chaces*, and two like compartments occur in the second gallery of the hazard side. The play begins from the dedans side, hence it is also known as the *service* side, and the game is played in *sets* of six games of four strokes each. A marker is required to note the progress of the play. See *The Annals of T.*, by Julian Marshall (*Field* Office, 1878).

Tenn'yson, Alfred, Poet-Laureate, was born in 1809 at Somersby, Lincolnshire, of which parish his father, the Rev. George Clayton T., was rector, his mother being a daughter of the Rev. Stephen Fytche. His father, a man of strong character and wide acquirements, conducted his early education, as well as that of his two elder brothers, Charles (now the Rev. Charles T.-Turner) and Frederick, both of whom have likewise published poems, the former being especially well known for the grace and delicacy of his sonnets. It was in conjunction with his brother Charles that T., then an undergraduate of Trinity College, Cambridge, made his first poetical venture, in the shape of a small octavo volume of 228 pages, entitled *Poems by Two Brothers* (Louth 1827). These attracted very little attention, and are said indeed to have shown but slight promise. Two years afterwards (1829), T. gained the Chancellor's gold medal at Cambridge for a poem on the subject of *Timbuctoo*, when he had for one of his competitors the friend whom he has since immortalised, Arthur Henry Hallam. His next publication, *Poems, chiefly Lyrical* (Lond. 1830), was reviewed by Professor Wilson in *Blackwood's Magazine* (May 1832) so harshly as to call forth a so-called 'epigram' from the young poet, in which he repaid 'crusty Christopher' in his own coin. His third volume, *Poems by A. T.* (Lond. 1833), did little to increase his fame, though it contained some of his best-known shorter pieces, such as *The Dream of Fair Women*, *The Palace of Art*, *The May Queen*, and *Œnone*. With a wisdom rare in young writers, he now kept silence for ten years, allowing his genius to ripen until it burst upon the world fully matured in the *Poems by A. T.* (2 vols. Lond. 1842). These at once gave him a foremost place among English poets, and his subsequent works have almost invariably added to his reputation. A proof of his growing fame may be found in the fact that Bulwer Lytton considered it worth his while in 1846 to make a violent attack upon 'school-miss Alfred' in his *New Timon*. To this T. rejoined in some intensely scornful verses published in *Punch*. In 1847 appeared *The Princess*, but it was not until the third edition (1850) that the poem assumed the form in which we now know it, with the intercalated lyrics. Seventeen years after the death of the friend it commemorates, *In Memoriam* was published (1850), and in the following year T. succeeded Wordsworth in the laureateship. His first work in his new capacity was the *Ode on the Death of the Duke of Wellington* (1852). *Maud* followed in 1855, four of the *Idylls of the King* (*Enid*, *Vivien*, *Elaine*, and *Guinevere*) in 1859, *Enoch Arden* in 1864, the remaining *Idylls* at intervals between 1867 and 1872, and lastly the dramas of *Queen Mary* (1875), and *Harold* (1876). T. is said to be engaged at present on a third drama on the subject of Thomas-à-Becket. His shorter poems have appeared at intervals in different periodicals (the *Examiner*, *Macmillan's Magazine*, *Good Words*, the *Nineteenth Century*, &c.), but have almost all been collected in the numerous and ever-increasing editions of his works. One or two patriotic songs, notably one beautiful lyric entitled *Hands all Round*, which appeared in the *Examiner* and in the *Times* about 1852, have been generally attributed to T., but have not been acknowledged by him. T. married in 1851, and has a numerous family. He resides for the most part at Farringford, near Freshwater in the Isle of Wight, and at Aldworth in Surrey, leading a very retired life, and seldom or never appearing in public. So uneventful has his life been that his biography almost merges into bibliography, and the best authorities for both are R. H. Shepherd's *Tennysoniana* (Lond. 1866), and an article on *The Bibliography of T.* in the *Fortnightly Review* (October 1865). See also J. H. Smith's *Notes and Marginalia on A. T.* (Lond. 1873), and *Tennysoniana* (2d ed. revised and enlarged, Lond. Pickering & Co., 1879).

Few poets have been subjected to so searching a criticism as T., and it cannot be said that a final verdict has yet been pronounced. There was a time when T. was considered the rarest poet that England had ever produced; when men thought that no verse had ever before attained such glow of colour or music of sound, and that no poet had ever chosen such noble, refined, and suggestive themes. The finer life of the nation, the grace, sweetness, purity, and simplicity of English homes, breadth of intellectual sympathy, ardour of hope, faith in freedom, and religious reverence, all found so genuine an expression in his writings that the generosity of youth could put no bounds to its admiration. If the future insists on some abatement of the glowing estimates of the past, if it becomes conscious of defects and limitations, and learns to feel the art more than the inspiration, one can hardly suppose that it will ever cease to experience delight in the most exquisite literary workmanship of the 19th c. Among the most systematic critical studies are E. C. Tainsh's *Study of the Works of A. T.* (Lond. 1869), and H. Elsdale's *Studies in the Idylls* (Lond. 1878). See also Kingsley's *Miscellanies* (Lond. 1859), Bayne's *Essays* (Edin. 1859), J. H. Stirling's *Jerrold, T., and Macaulay* (Edin. 1868), A. H. Japp's *Three Great Teachers* (Lond. 1865), Essays by Professor Dowden and Professor Ingram in *Dublin Afternoon Lectures* (Lond. 1863, &c.), Taine's *English Literature* (book v., chap. vi., Edin. 1874), Robert Buchanan's *Master-Spirits* (Lond. 1873), R. H. Hutton's *Essays* (2d ed. Lond. 1877), H. B. Forman's *Our Living Poets* (Lond. 1871), E. C. Stedman's *Victorian Poets* (Lond. 1876). The late F. W. Robertson published an interesting *Analysis of In Memoriam* (5th ed. Lond. 1873), and on the subject of this poem reference should also be made to the paper on A. H. Hallam in Dr. John Brown's *Horæ Subsecivæ* (new ed. Edin. 1875). The *Remains of Verse and Prose* of A. H. Hallam, privately printed in 1834, were published in 1863 (Lond.). There have been many illustrated editions of T., the best known being Doré's *Idylls of the King* (Lond. 1868). In conclusion we must refer to Brightwell's *Concordance to the Works of A. T.* (Lond. 1869). Many of T.'s principal poems have been translated into French, German, Italian, and Danish.

Ten'on (Fr. *tenon*, from Lat. *tenere*, 'to hold'), a projection at the end of a piece of timber for insertion into a hole or mortice of a corresponding size in another piece of timber.

Tenon and Mortise.

Ten'or (from *teneo*, 'I hold;' Ital. *tenore*), the highest of the three divisions of male-chest voices. Its range lies between tenor C, which few tenors take with certainty, and treble A. To this quality of voice was assigned the leading or sustained part in old church music, counterpart being added above and below it; hence the derivation of the name. The T. voice is particularly suited for sentimental and emotional songs. The leading male part in an opera is, with few exceptions, designed for a T. A T.-singer with a light kind of voice is called a *tenore leggiero*, one possessing a voice of full and powerful quality a *tenore robusto*. T. voices are most common in the S. of Europe, especially Italy, but are not unusual in the N., particularly among Celtic nations. The instrument known as the viola is sometimes called the T. The T. clef is the C clef placed on the fourth line of the staff.

Ten'or, Proving of. See PROVING THE TENOR.

Tenot'omy, or the subcutaneous division of tendons, is a surgical operation now very extensively practised in the cure of club-foot and other deformities. The operation was first practised by Stromeyer, who divided the tendo Achillis, in 1831, by subcutaneous puncture. The operation consists in passing a small thin knife through a minute puncture close to the contracted tendon, dividing it, if possible, without injuring any part in its vicinity. The puncture is carefully closed, and the wound generally heals by the first intention. T. is generally employed in the case of club-foot; sometimes to facilitate the reduction of

a fractured bone or a dislocation; also for squint and wry-neck, and various deformities.

Ten'rec or **Tan'rec** (*Centetes*), a curious genus of insectivorous mammalia, the common species of which is often named the 'Madagascar Hedgehog.' The *C. ecaudatus*, the common species, attains the size of an ordinary hedgehog. The T. has a covering of spines, which are variegated with black and yellow, and are about an inch long. The under parts are covered with coarse hairs. The T. feeds on worms, snails, small reptiles, and like fare. Although a powerful odour of musk is exuded from the T., the natives of Madagascar esteem the animal when cooked a luxury. Other species are the Spiny T. (*C. spinosus*), and the Banded T. (*C. Madagascariensis*).

Tense. See CONJUGATION.

Tent, a movable dwelling formed by canvas supported by poles or a light framework, and stretched and held down by ropes secured to pegs driven into the ground. Tents have always been the dwellings of pastoral tribes who wander from one fertile spot to another. During patriarchal times the covering materials were made of animals' skins and spun goats'-hair. The form of the primitive structure is most probably preserved in the present Arabian T., which is oblong in plan and 8 or 10 feet high, with sloping sides. Considerable ingenuity has been expended in modern times in the construction of tents for the use of emigrants, travellers, missionaries, sportsmen, and soldiers; combining the essential qualities of portability, capability of being expeditiously 'pitched' or 'struck,' and of resisting high winds, good ventilation and dryness. The 'bell-T.' of the

Travelling or Military Tent.

British service is 40 feet in circumference, with one central pole, and it accommodates from 12 to 14 men, who at night lie radially around the pole, their feet being towards it. Mr. Benjamin Edgington of London has designed a military or travelling T. which is in every respect superior to the bell-T. It is pyramidal in form, and the angles are strengthened from the head by a stout rope to which the canvas is 'bolted,' and which is secured by strong iron pegs to the ground, thereby constituting the main support of the T. A porch sustained by a light pole is formed at each of two opposite sides, giving entrances to the dwelling and affording a thorough draught of air. Ventilating apertures are also provided at the top. The central pole and the smaller poles are divided into lengths for convenience of packing. A T. of this description, 15 feet square, is capable of comfortably accommodating 16 men with knapsacks and rifles. As shown in the 'cut,' an iron chimney, connected with a warming, ventilating, and cooking stove, may be substituted for the centre pole. The chimney is supported by a tripod stand, the legs of which rest on a rack which prevents them sinking in the ground, and admits of the T. being raised or lowered according to the action of the weather on the canvas. A very simple, compact, and portable hammock-T., admirably adapted for the soldier, sportsman, or pleasure-seeker, has lately been invented and patented by Mr. C. H. Leycester, Gwynfè, South Wales. The 'Gwynfè' T., which was exhibited at the Paris Exhibition (1878), and was awarded a prize medal, consists of a secure slender framework of six short lengths of bamboo or ash tipped with metal, two of these fitting together to form a horizontal stretcher from which a hammock is slung and over which a waterproof sheeting is thrown. It stands by itself on any kind of ground, and dispenses with ropes, pegs, or trees. When folded for carriage it forms a light portable parcel. A large field T., such as is erected for out-door fêtes, is known by the name of *marquée*.

Ten'tacles, the name given to the tactile appendages common in lower animals (*e.g.*, sea-anemones, corals, zoophytes, &c.), and which subserve prehension and touch, or both of these.

Tentac'ulites, a curious genus of fossils occurring in Lower Silurian to Devonian Rocks, and of which *T. ornatus* (*U. Silurian*) is a familiar species. T. was formerly regarded as a genus of Tubicolar or tube-forming worms, but it is now believed by most palæontologists to be an extinct genus of Pteropoda.

Ten'terden, a market-town in the Weald of Kent, 18 miles S.E. of Maidstone, was anciently only 2½ but now is 15 miles from the sea, and still possesses the privileges of a Cinque Port. The noble Perpendicular steeple of its church is said by Kentish folk-lore to have been the cause of the Goodwin Sands, a Bishop of Rochester having diverted to its erection funds destined for the maintenance of sea-walls. Other buildings are a town-hall (1792), a Benedictine Priory, and a market-house. Pop. (1871) 3557, mostly agricultural.

Ten'terden, Charles Abbot, Lord, a barber's son, was born at Canterbury, 7th October 1762, and from the King's School of his native city passed to Corpus Christi College, Oxford. Having gained a scholarship, a fellowship, and two chancellor's medals, he was called to the bar (1795), and on the Oxford circuit soon made a considerable fortune. Created a puisne judge in the Court of Common Pleas (1816), he was knighted in 1818, and in 1827 raised to the peerage. He died at Bristol, 4th November 1832. His *Treatise of the Law relative to Merchant Ships and Seamen* (1802) is a standard authority on the subject.

Tenuiros'tres ('slender-billed'), a group or section of the Insessorial or perching birds, characterised by a long and delicate beak, which tapers to a point. The toes, as a rule, are also slender, and the hinder toe is especially long. These birds feed upon insects, and many subsist on flower-juices. The chief families included in this group are the *Certhidæ* (creepers), *Trochilidæ* (humming-birds), *Meliphagidæ* (honey-eaters), *Promeropidæ* (sun-birds), and *Upupidæ* (hoopoes).

Te'nures of Land. Nearly all the real property of England is supposed to have been granted by a superior lord, and to be held from him in consideration of certain services to be rendered to him by the tenant. By 12 Car. 2, cap. 24, military T. were changed into *Socage* (q. v.). See also BURGAGE TENURE; BOROUGH, ENGLISH; GAVELKIND; COPYHOLD. Under COMMON, COMMON TENANCY, FREEHOLD ESTATE, FEE SIMPLE. In Scotch law, see FEU HOLDING.

Teocall'i (= 'house of God') or **Teopan** (= 'place of God') were the names of the temples of the native Mexicans. They were generally solid, quadrilateral, truncated pyramids, built of earth cased with brick. On the upper surface were several large towers, forming the temple proper, and containing the images of the gods. The pyramid was surrounded by several slightly spiral terraces. A staircase ascended at one of the angles to the first terrace, which went round the building with a slight ascent till it came directly above the top of the stair; from this point another stair led up to the second terrace, and so on. Thus it was necessary to go round the building several times before reaching the platform at the top. On this platform a fire burned always, and was visible at a great distance. Human and other sacrifices were offered here. The T. were very numerous; every large town had several hundred. The best preserved are those at Cholula and Palenque.

Tep'litz. See TÖPLITZ.

Terai' or **Turrye'** (*tarai* from *tar*, Pers. for 'moist'), the name for the narrow strip of swampy jungle which uniformly underlies the lowest ridge of the Himalaya Mountains in the N. of India, continuously from Kumaon to Assam. This is about 15 miles wide, and is kept perpetually moist by rivulets, and by infiltration from a peculiar bed of boulders and sand, called *bahbur*, which immediately adjoins it above. It is overgrown with jungle and enormous grasses, the home of tigers and other wild beasts. At no time can it be healthy, and at certain seasons of the year the malaria is absolutely fatal to strangers, though the aboriginal tribe of Therus seem to flourish. Proceeding from the W., the first portion lies in the Rohilcund division of the N.W. Provinces, forming the *district* of T., with an area of 920 sq. miles, and a pop. (1872) of 185,658; the chief town is Kashipur. The next portion, bordering Oudh and Behar, lies chiefly within Nepaul territory. The third piece was annexed from Bhotan after the war of 1864, and is known as the E. and W. Duars.

Tera'mo (anc. *Interamna*), a town of S. Italy, province of Abruzzo Ultra I., on the left bank of the Tordino, 35 miles S. of Fermo, with manufactures of wax, cream-of-tartar, liquorice, leather, earthenware, straw-hats, and art-furniture. Pop. (1877) 20,138.

Ter'aphim (Heb., properly a plural, but used also, like Elohim, for a single object), as appears from a consideration of all the passages of the Old Testament in which the name occurs, seem to have been larger or smaller *images* which were perhaps worshipped as household gods by the Israelites from the earliest periods of their history (*cf.* Gen. xxxi. 19, 34, 35), till at least after the Captivity (Hos. iii. 4; Zech. x. 2, 'idols'). Not only was the prosperity of a family believed to depend on their possession (*cf.* Gen. xxxi. 35), but they were used as oracles, like the Ephod (q. v.), and consulted regarding the future (*cf.* Jud. xvii. 5, xviii. 3-6; Ezek. xxi. 21, 'images'; Zech. x. 2).

Teratol'ogy. See MONSTER, MONSTROSITY.

Ter'burgh, Gerhard, a Dutch painter, was born of good family at Zwolle in 1608. He travelled in Germany, Italy, Spain, and England, and wherever he went acquired a great reputation. He finally settled at Deventer, and there filled the office of burgomaster. His death took place in 1681. Among his paintings may be mentioned the portrait of William of Orange, the 'Father's Advice' celebrated by Goethe in his *Wahlverwandschaften*, and the 'Congress of Munster in 1648,' which was sold at the Demidoff sale for £7280, and was presented by Sir William Wallace to the national collection (see *Athenæum*, 1871). T. is remarkably successful in representing silks and satins, and many of his paintings have been evidently designed to show off his technical skill. Constantine T., his daughter, was an excellent copier of her father's works. T. is well represented in English private collections, and also in the galleries of Dresden, Munich, Vienna, Berlin, Amsterdam, and the Louvre.

Terce is one of the two *legal* liferents in the law of Scotland, being a real right constituted without covenant, or sasine. By it a widow, who has not accepted any special provision, is entitled to the liferent of one-third of her husband's heritable (real) estate, provided the marriage has lasted for a year and a day, or has produced a living child. If special provision is granted by a husband to his wife by any antenuptial or postnuptial contract or other deed, the wife shall be thereby excluded from her T., unless the contrary be provided in the same deed. The liferent bears its proportion of burdens affecting the estate. The mansion-house, if there be only one, feu-duties, rights of reversion, superiority, and patronage, are not subject to the right of T. For English law see DOWER.

Tercei'ra ('third,' so called from the order of its discovery), the second largest of the Azores, has an area of 220 sq. miles, with a pop. of 50,000. The coast is precipitous, and fortified where accessible, and the land rises so as to form a lofty central plateau, on which great numbers of cattle are reared. Maize, wheat, oranges, timber, and orchil are exported, but the wine produced is poor. The chief town, Angra (q. v.), is also the capital of the group.

Terebran'tia, a group or division of *Hymenopterous* insects which have a boring apparatus as the terminal appendage of the abdomen. By means of this they bore into the bark of trees for the purpose of inserting their eggs.

Terebrat'ula, a genus of *Brachiopodous* mollusca, forming the type of the family *Terebratulidæ*, in which the shell is minutely punctated, and the ventral or lower valve has a prominent beak, which is perforated by an aperture for the transmission of a muscular stalk or *peduncle*, by means of which the animal attaches itself to fixed objects. The arms are supported by a 'carriage-spring apparatus' of living loops, contained within the dorsal or upper valve. The loops are very short. T. is a genus, including several living species, of which *T. Australis* is familiar. Fossil species of T. commence in the Devonian Rocks, and are well represented onwards to the present day.

Tere'do or **Ship'worm** (*Teredo navalis*), a very peculiar species of *Lamellibranchiate* mollusca, belonging to the family *Pholadidæ*. Linnæus styled it '*calamitas navium*,' from the ravages it works on the timber of ships. It has at its anterior extremity two small shelly valves, the long wormlike body being formed by the *siphons* or breathing tubes, which are inclosed within a lining, covering, or encrustation. The shell is globular in shape, and is open in front, its valves being three-lobed. The ravages of the T. annually cost the British Government many thousands of pounds for repairs of timber at seaports. Holland has been more than once threatened with destruction from the attacks made by the T. on the wooden piles which support the *dykes* or mounds of that kingdom. The only certain preventive of T. attack is to drive large-headed nails into the exposed piles. A large species of T. (*T. gigantea*) occurs in tropic seas, and does good service in disintegrating and breaking up floating timber and driftwood.

Terek' (Armen. *Terchyk*), a river in Russian Caucasia, rises near Mount Kasbec, flows in an easterly direction, and enters the Caspian by many branches after a course of 350 miles. It has a descent, after reaching the plain (Mosdok), of 40 centimetres to the kilometre, and is utilised for irrigation in the district to which it gives name, and which is specially noted for its warm springs and petroleum-wells. The *district*, lying between the government of Stavropol and the highlands of Daghestan, has an area of 34,637 sq. miles, and a pop. (1876) of 485,237, mostly Mohammedans and Cossack settlers.

Teren'tius Afer, Publius, was born at Carthage, whence his surname *Afer*, B.C. 185 (*Teuffel*). Some authorities place him ten years earlier. Following immediately after Cæcilius, the most popular representative of Roman comedy after Plautus, he was the last of the comic dramatists of Rome of whom we have anything remaining. The extant records of the life of T. are more than apocryphal. His history, so far as it seems worthy of acceptance, may be briefly given. T. was either taken prisoner in war or sold in the slave-market. His purchaser, or at all events the Roman into whose hands he fell, was a senator, Lucanus Terentius. On obtaining his freedom he took his patron's name. A liberal education followed, and we soon find him the friend and associate of the great and noble. T. was gifted with dramatic genius. Whether his plays were his unaided productions, or were amended by his patrons Lælius and the younger Scipio, matters but little. The works that bear his name are as much his genuine compositions as are the plays of our own Colman, Cumberland, or Gay, whose dramas were admittedly combed and corrected by competent hands before representation. T. was beyond question the chief dramatist of his time. He used, moreover, the Latin tongue with singular grace and elegance. Critics have denied to him the possession of lively humour (*vis comica*). Ancients and moderns, however, are agreed that, although a freedman and a foreigner, he divides with Cæsar and Cicero the palm of pure Latinity. T. was the interpreter of Menander; but he was more than a mere translator. His six comedies that remain belong to the *Fabula Palliata*. It is said that T. went to Greece, and translated 108 of Menander's plays. Whether he was lost on his homeward voyage, as some say, or lost his transcripts and died of grief in consequence, we have no means of deciding. Probably his stock consisted of little more than notes: translations could hardly have been produced during his brief sojourn. T. died in his twenty-sixth year, 159 B.C. He owned an estate of twenty *jugera* contiguous to the Appian Way, and after his death his only daughter married a Roman knight. The following are his comedies, with the years of their production:—(1) *Andria*, 'The Woman of Andros,' B.C. 166; (2) *Hecyra*, 'The Stepmother,' B.C. 165; (3) *Hautontimoroumenos*, 'The Self-

Tormentor,' B.C. 163; (4) *Eunuchus*, 'The Eunuch,' B.C. 162; (5) *Phormio*, B.C. 162; (6) *Adelphi*, 'The Brothers,' B.C. 160.

The *editio princeps* of T. was published at Strassburg in 1470. Other noteworthy editions are those of Muretus (Ven. 1555), Madame Dacier (Par. 1688), Bentley (Camb. and Lond. 1726), A. Fleckeisen (Leips. 1857), Parry (Lond. 1857), W. Wagner (Camb. 1869). See Dunlop's *Rom. Lit.*, vol. i. p. 110, *et seq.*; Dryden's *Essay on Dramatic Poesie*; *Plautus and T.*, by the Rev. W. L. Collins in Blackwood's *Ancient Classics for English Readers* (Edinb. 1873); and Francke, *T. und die lateinische Schulkomödie in Deutschland* (Weim. 1877). The works of T. have been translated into almost every European tongue.

Tere'sa, St., Spain's patroness, was born of the noble Cepeda family at Avila, in Old Castile, 28th March 1515. Losing her mother at the age of twelve, she gave herself up to reading tales of chivalry and to girlish coquetry, till in 1531 her father placed her in an Augustinian convent. Here the desire seized her of entering the religious life; during an illness she sought her father's leave, and, though he withheld it, was received as novice by the Carmelites of her native town, 2d November 1533. 'Her passionate nature,' to quote George Eliot's *Middlemarch*, 'demanded an epic life. What were many-volumed romances of chivalry and the social conquests of a brilliant girl to her? Her flame quickly burnt up that light fuel, and, fed from within, soared after some illimitable satisfaction, some object which would never justify weariness, which would reconcile self-despair with the rapturous consciousness of life beyond self. She found her epos in the reform of a religious order.' Yet was she long in finding it—nigh thirty years, passed under the Mitigated Carmelite Rule, being chiefly marked by T.'s frequent illnesses, her father's death (1541), her yearnings towards the world, and her perusal of the *Confessions of St. Augustine*. Then came two years and a half of 'intellectual visions' (1559-61), during which she conceived the notion of restoring the original severe Rule of her order. Good and learned men regarded her inspirations as satanic delusions, her seeking after a stricter life as presumptuous, but in 1562 she obtained from Pius IV. a bull allowing her to found the little convent of St. Joseph, where with twelve nuns she gave herself up to rigid asceticism. Her reforms were extended during her lifetime to 17 convents and 16 monasteries, but T. herself remained a simple nun till 1581, when she was chosen prioress of the convent of Avila. She died at Alba de Tormés, in Leon, 4th October 1582; and in 1621 she was canonised by Gregory XV. Founder of the Spanish mystic school, T. yet was ever saved from fanaticism by her excellent commonsense. Her classic *Obras* (Sal. 1588; 2 vols. Mad. 1861-62), containing her autobiography, letters, *El Camino de perfeccion*, *Las Fundacionnes de las Conventos de las Carmelitas*, &c., enshrine the genius, candour, and fascination of the only woman on whom has been conferred the title of 'Doctor of the Church.' See M. Trench's *Life of St. T.* (Lond. 1875).

Terliz'zi, a thriving town of Italy, in Apulia, province of Barri della Puglie, 8 miles S.W. of Molfesta, with mediæval remains, and exports of wine, oil, and fruits. Pop. (1874) 18,261.

Term. The terms for the sitting of the law courts in England are Hilary, Easter, Trinity, and Michaelmas. The terms for paying rent in England and Ireland are Lady-day (March 25), Midsummer-day (June 24), Michaelmas-day (September 25), Christmas-day (December 25). In Scotland the money terms are Whitsunday (May 15) and Martinmas (November 11). Houses in Scotland are usually let from 26th May for a year or a period of years.

Ter'mini Imere'se, a thriving seaport on the N. coast of Sicily, on a promontory at the mouth of a river of the same name, 23 miles E.S.E. of Palermo by rail. It has considerable fisheries of tunny and anchovies, and its macaroni (*pasta*) is considered the best in Sicily. Pop. (1877) 21,389. T., the ancient *Thermæ Himærenses*, was founded by the Carthaginians in 407 B.C., and fell into the hands of the Romans in 252. Many Roman remains exist, and a fine collection of antiquities is preserved in the Liceo.

Ter'minus, a Roman divinity, identical, according to Ovid (*Fasti* ii. 639 *et seq.*), with Jupiter, was reverenced from the earliest times as the protector of the boundaries of property both public and private. His festival, the *Terminalia*, was celebrated with bloodless sacrifices at the *termini* or boundary-stones.

Ter'mites, the scientific appellation of the 'White Ants,' insects belonging to the order *Neuroptera* (q. v.). The head in the T. is short, and the antennæ are 20-jointed. The abdomen is ovate, and the mandibles are small and triangular. In *Termes* itself the head is large and rounded. White ants occur in tropical climates. In Africa, for instance, they construct large nests, and live in social colonies which exhibit a high degree of organisation. The male and female are winged, and resemble each other. The *neuters* or *workers* are divided into *ordinary workers* which perform all the duties of the colony, and *soldiers*, provided with large mandibles, by means of which the defence of the colony is secured. Some of the workers (*Nasuti*) have a long protuberance in front of the head. The wingless T. are asexual, the work of reproduction being performed by the winged and sexual forms. The nest occasionally attains a large size. It is divided internally into chambers and galleries, and contains apartments set apart as nurseries and as feeding-places for the young. The nest of some species (such as *Termes fatale*) may resemble conical hillocks, and often attain a height of 12 feet. After impregnation, the females become wingless. Their bodies swell enormously as they become gravid with eggs, the abdomen sometimes measuring 2 inches, and the eggs being often deposited to the number of 80,000 per day. The common termite, or white ant of America, is the *Termes flavipes*. It occurs under stones and wood, and is of a chestnut colour, the head and prothorax being blackish brown. The workers are white, with yellowish heads. *Termes lucifugus* is a French species, the young or pupæ of which were found by Latreille to be provided in the spring with four wing-pads. This latter species is destructive to wood; while *Termes flavicolus* injures the Spanish olive-trees.

Tern or **Sea Swallow** (*Sterna*), a genus of birds belonging to the order *Natatores*, or swimmers, and to the family *Sternidæ*. The bill is long, slender, and straight; the wings are long, powerful, and pointed; the tail is forked; and the first quill is the longest. The hinder toe is short, and not united to the other toes by membrane, and the legs are also short. The *Sterna hirundo*, or common T., is a familiar sea-bird, flying abroad with great activity in the stormiest weather. It attains a length of from 12 to 15 inches, and is black above mixed with ashy grey, and white beneath. The legs, beak, and feet are red. An allied species is Wilson's T. (*Sterna Wilsonii*).

Terna'te, one of the Moluccas (q. v.), to the W. of Gilolo, has a volcano 4925 feet high, is covered with tropical vegetation, and produces great variety of spices. The town of T. (pop. 6000), the seat of a Dutch resident, is defended by Fort Oranien. The *Dalem*, or palace of the sultan, is a grand building.

Ter'ni, a town of Central Italy, province of Perugia, between two arms of the Nera (*Nar*), 50 miles N.N.E. of Rome by rail. The seat of a bishop, it has a cathedral, several palaces, ruins of an amphitheatre, an institute for mechanics, &c. There are cloth, silk, and leather industries, and considerable culture of oranges, olives, and the mulberry. Pop. (1875) 15,500. The ancient *Interamna*, it is the supposed birthplace of Tacitus. In the vicinity is the famous waterfall of Velino. At T. the Neapolitans were defeated by the French, 27th November 1798.

Ternstrœmia'ceæ, a natural order of thalamifloral *Polypetalæ* containing about 300 species found round the world in the tropics. Of these the beautiful cultivated Camellia (q. v.) is perhaps the best known, and the Tea Shrub (q. v.) is the most important. *Gordonia lasianthus*, the loblolly bay of America, is a handsome tree growing to a height of 60 feet, and bearing snowy-white flowers; its bark is extensively used for tanning in the Southern States. *Kielmeyeria speciosa* of Brazil has flowers resembling the mallow, and possesses mucilaginous properties, a decoction being employed for fomentations. The leaves of *Freziera theoides*, a common W. India species, are astringent, and have a taste like tea, for which they are locally made a substitute.

Terpsi'chore (Gr. 'the dance-enjoying') appears in the *Theogony* of Hesiod as one of the nine Muses (q. v.). In later times she especially presided over choral song and dancing.

Terraci'na (the *Anxur* of the ancient Volsci and the *Tarracina* of the Romans), a town of Italy, in the province of Rome and district of Velletri, on the sea-coast, at the S.E. extremity of the Pontine Marshes, 11 miles S.W. of Fondi. Its harbour, anciently a Roman naval station, is now filled up. T. is an epis-

copal seat, and has a cathedral of S. Pietro built on the site of an ancient temple of Jupiter Auxurus, while on the summit of the promontory and overlooking the town is the palace of Theodoric, afterwards converted into a castle. T. was important in ancient times as commanding the pass on the Appian Way between the mountains and the sea. Pop. (1874) 7376.

Terr'a Cott'a (It. 'baked clay') is simply a superior variety of brickwork made with a fine clay, and often modelled or worked into highly artistic forms, or used in architectural or decorative structure. From classical times T. C. was a favourite substance for statuary figures and statuettes, as well as for ornaments *en relief;* and during the Middle Ages it was extensively employed in architecture, especially in Italy. Recently T. C. has come into great favour in London as a decorative building material, and in the pottery of Doulton & Watts at Lambeth, groups, statuary figures, and relief works have been produced which show extraordinary skill and energy of modelling, and great technical dexterity in dealing with the material. T. C. should be close and smooth in texture, and ought to keep a fine bright colour under exposure to a smoke and acid-laden atmosphere.

Terr'a Firm'a (Span. *terra firme*), a term sometimes used to denote the 'Spanish Main' or the N.W. coast of S. America; or the part of the Italian mainland once subject to Venice, and more popularly to denote land as opposed to water.

Terr'a Japon'ica. See CATECHU.

Terrano'va (anc. *Gela*), a town on the S. coast of Sicily, 41½ miles S.E. of Girgenti, stands on a hill. In 1874 there entered 172 vessels of 14,931 tons, and cleared 190 of 10,882 tons, the exports (cotton, fruit, sulphur, &c.) amounting to £105,811, the imports to £74,893. It was founded by the Emperor Friedrich II. Pop. (1874) 14,686. T. is also the name of a small town on the N.E. of Sicily. Pop. 3500.

Terr'apin, a general name applied to various species of freshwater tortoises belonging to the family *Emydidæ*. The group includes the river and marsh tortoises, in which the jaws are horny and have cutting edges, the tympanum of the ear is exposed, and the limbs have each 5 toes united by a web. In the T. or 'Terrapenes' proper the pelvis is free, and the neck is capable of being bent in a vertical plane. The head is almost entirely hidden by the carapace when retracted. The principal genera of T. are *Emys* (q. v.), *Cistudo,* and *Chelydra.*

Terre Haute, capital of Vigo county, Indiana, U.S., on the Wabash River, about 150 miles W. of Cincinnati, and 170 N.E. of St. Louis by rail. The surrounding district (known as Harrison Prairie) is one of the most fertile in the States, and at the same time well provided with coal, hence T. H. has grown with a rapidity unusual even in American cities. It is an important railway centre, has fine churches and public buildings, and supports several newspapers. Pop. (1876) 25,000.

Terres'trial Mag'netism. At every point on the earth's surface a magnetic force acts, having a definite direction and magnitude. To completely fix this force three co-ordinates must be given; and these are usually the *declination* or azimuth of the force, the *dip* or inclination to the horizon, and the total *intensity.* These so-called magnetic *constants* vary from place to place upon the earth's surface, and their experimental determination is now an important item in meteorological science, and should be made at as many stations as possible. It is not enough, however, to make one determination, for observation has established that the declination and dip not only vary from place to place, but vary from hour to hour and day to day at any one place. The declination, which is measured by means of a delicately-suspended magnet free to rotate round a vertical axis, is always measured as so many degrees E. or W. of north. Thus at Greenwich the declination is at present 18° 45' W. of N., in 1850 it was 22° 29'·5 W. of N. It appears, then, that for this place the declination is subject to a gradual secular variation, and the same has been established for every place at which observations have been made. Not only so, however, but the declination is subject to a periodic *annual* variation and a periodic *diurnal* variation, which are subject to a greater variation whose period is about 10½ years. At certain times, when so-called magnetic storms are raging, these oscillatory variations are very marked, and their connection with auroræ boreales and sun-spots may be regarded as now thoroughly established. The declination has been observed as much as 43° 14' W. of N. at Reykavik, Iceland, and 31° 38' E. of N. at Port Etchez, N. America. The declination is very small for places in the S. of Asia. A line drawn through points which have the same declination is called a magnetic meridian or isogonic line, and all such lines meet in two regions on the earth's surface known as the magnetic poles, which, however, are not diametrically opposite each other. There are corresponding lines, called *isoclinic lines,* connecting places which have the same *dip.* The determination of the dip or angle of inclination which a magnet, set in the magnetic meridian and suspended so as to have free rotation round a horizontal axis through its centre of mass, is a much more difficult investigation. It is effected by means of the Dipping Needle (q. v.). The isoclinic line, for which the dip is zero, is called the magnetic equator, and at the magnetic poles the dip is 90°. South of this magnetic equator, the dip is *negative, i.e.,* the S. pole of the magnet dips down and the N. pole points up. The declination and dip for a given place determine the direction of the lines of magnetic force, to fix which completely requires the total intensity of the force in this direction. This intensity is not usually given, but only its horizontal component, the measurement of which is more easily effected experimentally. It is measured by observing the time of oscillation of a small magnet whose magnetic moment is known (see MAGNETISM). According to Airy, the locality of greatest horizontal magnetic intensity is in latitude 0°, longitude 259° E., where its value is ·3733, expressed in centimetre, gramme, and second (see UNITS). At Greenwich the mean horizontal intensity is ·1794; and the total intensity, taking the dip (67° 35') into account, ·4704. The greatest total intensity is in South Victoria, where its value is ·7898; and the least total intensity is near St. Helena, where its value is ·2828. The theory of T. M. has occupied the attention of some of our greatest mathematicians and physicists. Gilbert, and, following him, Euler, regarded the earth as a bar magnet with two poles; Halley and later Hansteen claimed two magnets and four poles as giving results agreeing better with observation. The first to place the theory in a satisfactory state, however, was Gauss, who, freeing himself from all speculation as to the *origin* of the earth's magnetic force, and assuming only a *polarity* characterised by repulsions and attractions acting according to the inverse square, developed a mathematical expression called the Potential Function (see POTENTIAL), upon which the distribution of magnetism throughout the earth depended. This function, though quite indeterminate on account of our ignorance of this distribution, must have certain properties from which Gauss deduced several wonderful results. Thus he proved that there was only *one* N. pole and *one* S. pole, and that given the N. component of the horizontal intensity for all places on the earth's surface, the E. or W. component follows. See Gauss's *Atlas des Erdmagnetismus,* and Clerk Maxwell's *Electricity and Magnetism.*

Terre-Plein, in Fortification (q. v.), is the platform upon which the guns are placed and worked.

Terr'ier, a name widely applied to certain breeds of dogs, usually of small size, but exhibiting very great variations in colour, hair, and general conformation. The name, indeed, has little or no special significance, but indicates any small breed of dog, and perhaps most specifically the rough-haired varieties used in killing vermin. The chief varieties of T. are the Scotch, Skye, and English T., the latter being a smooth-haired breed, of which the purest colour is black-and-tan. The Fox T. is more properly called a Foxhound (q. v.), and the Bull T. is a cross between the T. and Bull Dog (q. v.).

Terschell'ing, the third in the chain of islands stretching N. from the peninsula of N. Holland, lies near the entrance to the Zuider Zee. Area, 45 sq. miles; pop. (1876) 3128, mostly engaged in shipbuilding, fishing, and pilotage. Its fertile meadow-lands are protected by dykes, and there is a good harbour at Westerschelling. William Barentz was born here.

Ter'tian Fe'ver. See AGUE.

Ter'tiary Sys'tem, the whole series of stratified rocks intervening between the Cretaceous epoch and the period of the glacial drift. It is divided into three groups, known as the

Eocene, Miocene, and Pliocene formations, which as they approach nearer to the present time show evidences of gradually increasing similarity in the conditions of things, and a greater resemblance in their fauna and flora to those of our own age. Thus, taking for example the species of shells, we find, according to M. Deshayes, that in the Eocene rocks 3 or 4 per cent. only are identical with living forms; that this percentage in the Miocene is about 17, and finally attains 90 per cent. in the Newer Pliocene. The fauna of the Tertiary epoch is especially remarkable for the increasing development of mammals, and the flora for the great preponderance of dicotyledonous plants. In Britain the greatest exhibition of Tertiary strata is to be found in the south-eastern counties of England; for example, the London clay, and the 'Crag' formations of Norfolk and Suffolk.

Tertullia'nus, Quin'tus Septim'ius Flor'ens, first of the extant Latin fathers, was born about 160 A.D. at Carthage, the son of a proconsular centurion. Brought up a pagan, he was carefully educated in Roman law, more carefully still in Roman rhetoric; and probably he practised as an advocate in Rome itself. After his conversion, whenever that may have taken place, he is said to have been ordained a presbyter, and to have married a Christian wife; but he only continued orthodox till he had reached the middle term of life, going over then to the heresy of the Montanists (q. v.). This defection St. Jerome ascribes to the envy and ill-treatment which T. experienced from the Roman clergy; Maurice, on the other hand, regards it as 'a submission of the intellect, a voluntary abdication of his own judgment.' Be this as it may, a Montanist T. died, at an extreme old age, somewhere between 220 and 240 A.D. His was no lovable character, as shown to us in his works. These savour too much of the law—the law, not of an impartial judge, but of a special pleader. His adversaries, whether pagans, or the Orthodox whom he had lately quitted, or the heretics to whom he should soon desert, could look for no fairness or mercy at his hands. Thus in his *De Spectaculis* he says of the Day of Doom, 'How I shall laugh, rejoice, exult to behold so many sage philosophers blushing in red-hot flames!' in the treatise *De Anima* he argues that since nothing could be known regarding immortality but what God chose to reveal, therefore Socrates was more devil-inspired than ordinary heathens; the peroration of his *Libri Adversus Marcionem* is a singular instance of thieves—here heretics—falling out. Conversely his client for the time being he loaded with fulsome flattery, in the same *De Anima* contrasting Socrates with a Christian martyr, 'who did not swallow the cup with a sort of luxurious enjoyment, but endured to be burnt alive.' Such are some of the defects of T.'s matter; they are not redeemed by his fantastic style, bristling with barbarous terms, uncouth expressions, and far-fetched metaphors. The value of T.'s writings lies in their liveliness and vigorous force, the stubborn conviction that T. alone can be right, and especially in the large store of information they furnish respecting the doctrine and discipline of the Early Church. We have in all 31 of his works extant, some of which may with tolerable certainty be assigned to his Orthodox and others to his Montanist period, *e.g.* to the former the *De Baptismo*, *De Pœnitentia*, and *De Præscriptione Hæreticorum*; to the latter, the *Adversus Marcionem*, *De Carne Christi*, and *Adversus Praxeam*. When, however, his celebrated *Apologia* was written will probably never be determined. Of the numerous editions published since 1521 the best are those by Leopold (4 vols. Leip. 1839-41) and Oehler (3 vols. Leip. 1853); and there is a good English translation in the *Ante-Nicene Library* (4 vols. 1868-70). See Maurice's *Lectures on the Ecclesiastical History of the 1st and 2d centuries* (Camb. 1854), Böhringer's *T.* (Stuttg. 1873), Hauck's *Tertullians Leben und Schriften* (Erlang. 1877), and Bonwetsch's *Die Schriften Tertullians, nach der Zeit ihrer Abfassung untersucht* (Bonn. 1878).

Tesch'en (Slav. *Cieszyn*), a town of Austrian Silesia, and the capital of the duchy of the same name, on the river Olsa, 18 miles S.E. of Oderburg by rail. It has two gymnasia with libraries (one Roman Catholic and the other Protestant), manufactures of cloth, leather, &c., one large flax-work and spinning-mill. Pop. (1870) 9779. The treaty between Maria Theresa and Friedrich II., which put an end to the War of the Bavarian Succession, was concluded here, May 13, 1779.

Tess'elated Pave'ment, a mosaic pavement composed of coloured Tesseræ (q. v.) arranged to form a regular pattern or a picture. T. P. was made by the ancients. Many examples of Roman workmanship have been brought to light in England and other localities. Theatrical and battle scenes exquisitely executed with coloured stones have been discovered at Pompeii.

Tess'eræ (plur. of Lat. *tessera*, 'a die or token') are small earthenware, marble, or glass tiles of geometrical form, used for tesselated pavements, ornamenting walls, &c.

Test Acts, the name given to two statutes of Car. II. which imposed certain oaths on the holders of public offices; the object being to ascertain if the person taking them was loyal, and of the Protestant religion. They were modified by 9 Geo. IV. cap. 17. The T. A. are now superseded by the oath of Abjuration (q. v.).

Tes'tament. See BIBLE.

Tes'tament (in law). See WILL.

Tes'ticle or **Tes'tis**, the name applied to the essential organ of the male reproductive apparatus. In higher animals the T. number two, and are enclosed in a *scrotum*, or sac of loose tissue, covered with skin. In some forms (*e.g.* whales and elephants) the T. are permanently retained within the abdomen, as indeed is the case with all animals below mammals; while in other mammals (*e.g.* Rodentia), again, the T. pass periodically at the breeding season from the abdomen into a temporary scrotum. In man the testicles are two oval bodies, suspended in the scrotum by the *spermatic cords*, which are attached to the hinder border of these organs. The average length of a T. is about 1½ or 2 inches, its weight averaging from 6 to 8 drachms. The left T. is larger than the right. The serous membrane covering the T. is the *tunica vaginalis*, the *tunica albuginea* is its fibrous investment, and the *tunica vasculosa*, consisting of a network of bloodvessels, serves as its vascular layer. The *structure* of the T. exhibits numerous *lobules*, variously estimated as existing to the number of 200 to 400 in each organ. The lobules consist of delicate *tubes* (*tubuli seminiferi*), which end in the *vasa recta*, a series of straight tubes, and these again terminate in from 12 to 20 small ducts, the *vasa efferentia*. The latter ducts end in the *epididymis*, which in its turn is continued to form the *vas deferens*, or excretory duct of the T., which opens into the urethra. The *seminal fluid* of the T. is secreted in the *tubules* of the T., and stored in the *seminal vesicles* situated at the base of the bladder.

Diseases of the T.—The most common disease of the testicle is *Hydrocele* (q. v.), a collection of fluid in the tunica vaginalis, the result of over-secretion or passive dropsy. *Encysted hydrocele* of the testicle consists in the formation of a cyst in contact with the testicle itself, and not with the cord, usually situated in the head of the epididymis, and containing a milky secretion. Mr. S. Osborn traces the development of these cysts to the 'hydatid of Morgagni,' a small cystic body which is always found between the testis and the globus major, and is the remnant of the Müllerian duct. The treatment is the same as that of common hydrocele. *Hæmatocele* (q. v.) is a collection of blood in the cavity of the tunica vaginalis which may be caused by a sprain or injury, or by spontaneous rupture of or exudation from some vessel in the lining of the sac. Hæmatocele has a more rounded shape than hydrocele, is heavier, less homogeneous, opaque, and is often accompanied by a dark colour of the scrotum. The treatment consists in laying open the tumour by a free crucial incision, removing the clots, arresting hæmorrhage by ligatures, and allowing the cavity to heal by granulation. *Orchitis* (q. v.) may be acute or chronic, and is frequently associated with tuberculosis. *Cystic* disease of the testicle is usually malignant, with one or more cysts in it; but there are cases of innocent tumour formed by a number of cysts. *Congenital tumours* may contain portions of bone and cartilage, and are probably cases of scrotal *inclusion*, or dermoid cystic tumours. Dr. M'Ewan, of Glasgow, removed a tumour of this kind in the Royal Infirmary, in 1877, containing hair, skin, fibrous tissue, cartilage, and bone, the structure consisting essentially of an independent development inclosed, and leading a parasitic life in the scrotum of the patient. *Enchondroma* of the testicle is generally associated with cystic disease, the cysts being dilatations of the tubuli seminiferi, depending on deposits therein. *Cancer* of the testicle is generally of the encephaloid variety, begins in the body of the gland, and contains large cysts and masses of cartilage. Cancer tends to spread up the cord, and

into the glands which lie around the aorta and common iliac arteries. Death then ensues either from pressure of the mass in the abdomen, or from its interference with digestion. See Curling's *Diseases of the Testis*, &c. (1878).

Testimo'nium is the clause of Attestation (q. v.), beginning 'In witness whereof.'

Tes'ting Clause, in a Scotch deed, is the clause by which its execution is authenticated. The name and designation of the writer, mention of the number of pages in the deed, and the names and designation of the witnesses, are statutory requisites to all deeds, unless Holograph (q. v.). In English law, see ATTESTATION, SIGNING, SEALING, and DELIVERY.

Testu'do (Lat. *testudo*, 'a tortoise'), in Roman warfare, an unbroken scale-like covering formed by foot-soldiers holding their shields horizontally over their heads, and designed as a protection from darts and other missiles. In an attack on a besieged fortress, a T. sloping gently from the first down to the last rank was invariably formed, and over this inclined platform other soldiers advanced to engage the enemy on the walls. A wheeled and covered machine which sheltered soldiers while working under the walls of a city was also known as a T.

Testu'do. See TORTOISE.

Tet'anus (Gr. *teinein*, 'to stretch'), or **Locked Jaw**, is an affection characterised by tonic spasms of the muscles, especially of the jaw, neck, back, and lower extremities, and is never attended by loss of consciousness. T. may be idiopathic or traumatic, and may be a condition at birth called *trismus nascentium*. The symptoms of T. may be ushered in by general discomfort, the patient being unable to masticate or swallow his food as usual; but the first decided symptoms noticed are stiffness of the neck, soreness of the throat, and a contraction of the jaws, which may become more complete within the fourth or fifth day of the affection. The features become pinched and set; the corners of the mouth are drawn upwards; the eyes are prominent, the brows are knit, and the hair and eyebrows are bristling, the whole constituting the *risus sardonicus*. The closure of the jaws is often so complete as to render it necessary to give food through small tubes or quills; and sometimes spasms of the pharyngeal muscles render swallowing impossible. The muscles of the back and lower extremities are convulsed, giving rise to *opisthotonos*, so that the patient's body describes an arc, the head and heels touching the surface on which he is lying, and the middle of the back being raised for some distance therefrom. Sometimes *emprosthotonos* ensues, the body being bent in the opposite direction; and, at other times, *pleurosthotonos*, when the muscles upon one side of the body are contracted. The pulse throughout is rapid and fluttering, the respiratory movements are irregular and catching; the dyspnœa is very distressing; the skin is dark; the face is haggard and depressed; there is profuse perspiration and a very marked elevation of temperature, which may rise as high as 110°. Death generally results from spasmodic closure of the glottis, or from exhaustion. Infantile T., or *trismus nascentium*, may appear from the first to the fifth day after birth, the symptoms being restlessness, trembling of the lower jaw, followed by spasms and rigidity of the muscles of the jaw, and the other symptoms of T. already described. The causes of T. are, exposure to damp and cold; accidents during parturition; punctured wounds; injuries in which there are crushing and mangling, such as railway accidents, and, occasionally, surgical operations. In certain regions there are apparently endemic influences, or modes of life, which seem to favour the origin of T., which is much more common in tropical than in temperate climates.

The morbid anatomy and pathology of T. is very obscure, and our knowledge is based almost entirely upon the experiments of physiologists. Dr. Lockhart Clark, however, in 1865 found, in six cases of T., that there was degeneration of the grey substance of the spinal cord; and Dr. James Tyson, in 1877, described two cases in which softening of the posterior columns occurred. In one of these cases there was extravasation of blood in the posterior columns; and, in the other, venous congestion. T. bears some resemblance to strychnine poisoning. The cases of death in cases of T., in the British army during the Crimean war, was 91 per cent., nearly the same as occurred in the French army under the first Napoleon. Dr. Joseph Jones, of New Orleans, in 1876 collected 480 cases of T., all of traumatic origin, and found that 213 recovered under treatment, the mortality being 49·2 per cent., or one death in 2·02.

Treatment.—The most efficacious remedial agents in the treatment of T. are chloroform, chloral hydrate, Indian hemp, Calabar bean, and conium. Calabar bean has been used with great success, and may be given in doses of from ¼ to ½ of a grain of the extract every two hours. The chloral treatment has been still more successful, and the chloral may be combined with Cannabis Indica and bromide of potassium. Chloroform subdues the symptoms temporarily, but is not curative. Cold to the spine, applied by the ether spray, has been recommended by Carpenter, and is probably the best mode of treatment.

Tête de Pont ('head of a bridge'), in fortification, a fieldwork, generally open at the gorge, with its flanks on the banks of a river. It is designed to cover one or more bridges.

Tetrago'neæ, a sub-order of *Ficoideæ*, including the apetalous plants of that order. Professor Lindley placed the same as a separate order near to *Chenopodiaceæ* under the name *Tetragoniaceæ*. The large type-genus *Tetragona* is chiefly S. African, with a few Japanese, Australian, New Zealand, and American species. *T. expansa* is a useful culinary vegetable known as New Zealand Spinach (q. v.), and *T. implexicoma* is serviceable in like manner.

Tetrahe'dron (Gr. *tetra*, from *tessera*, 'four,' and *hědra*, 'a side'), in geometry, is a regular solid, bounded by four equilateral triangles, so that when set upon any side it has the appearance of a triangular pyramid. In crystallography, the T. is regarded as a secondary form of the octahedron, from which it is derived by cutting away the alternate angles or edges.

Tet'rao. See GROUSE.

Te'trarch (Gr.), literally, the ruler of the fourth part of a country, in the later days of the Roman republic and under the empire, denoted, like ethnarch and phylarch, petty tributary kings. Thus the title was given to Herod the Great and his brother Phasael (Jos. *Ant.*, xiv. 13, 1), without reference to territorial divisions; although Herod's sons, Antipas and Philip, to whom the title is also applied (Luke iii. 1), did receive a fourth part of their father's possessions, and Archelaus as ethnarch got a half (Jos. *Ant.* xvii. 11, 4; *Bell. Jud.* ii. 6, 3).

Tetuan', a Spanish possession on the Mediterranean coast of Morocco, having an area of 914 sq. miles, and a pop. of 18,000. The town lies on the river Martil, four miles from its mouth, and is strongly fortified. Though accessible only to vessels of small size, T. has an active coasting and foreign trade in wool, silk, cotton, leather, oranges, and live stock. In 1877 there entered 181 vessels with cargoes of £29,630 value, and cleared 187 with cargoes of £10,244 value. T. was taken by Spain in 1860, and confirmed to that country by the Treaty of Madrid in 1861.

Tetz'el, Johann, preacher and seller of indulgences, was born about 1455 in Leipzig. He studied with some distinction at the university of his native town, and in 1489 entered the Dominican cloister of St. Paul there. He soon acquired a wide renown as a popular preacher, and in 1502 was commissioned from Rome to vend indulgences, a work so congenial to him that he made it the pursuit of his life. In 1516 he was appointed one of the officials to collect money by this means for the building of St. Peter's at Rome. His boldness and effrontery, his extravagant and immoral life, soon made his name notorious over the whole of central Europe, and there can be no doubt that the conduct of this accredited official of the Church did much to hasten the Reformation. It called Luther into the field. At last his ecclesiastical superiors became convinced of the harm he was doing. He was summoned before Miltitz, the papal legate, who severely condemned his conduct, and threatened him with punishment from Rome. In fear and dismay T. retired to his native town, where he died, as Luther has remarked, 'probably from the reproaches of his conscience and the Pope,' in July 1519. Lives of T. have been written by Gottfried Hechtius (Witt. 1717), Vogel (Leip. 1717-27), F. G. Hofmann (Leip. 1844). See Kayser, *Geschichtsquellen über T.* (Annab. 1877).

Teuth'idæ. See SQUID.

Teu'toburger Wald', a mountain-chain of Prussia, in the districts of Minden and Lippe-Detmold, which, beginning on the left bank of the Diemel, between Warburg and Stadberge (where it is named *Egge*), runs first N. then N.W., forming first the watershed between the Rhine and Weser, then between the Ems and Weser, and after reaching a total length of 110 miles, and a height of 1400 feet, ends at Bevergern, near the Ems, in Westphalia. The T. W. is noted for the destruction of the legions of Varus by Hermann in 10 A.D.

Teu'toni (Cicero, Livius, and Mela) or **Teu'tones** (Pliny), a German tribe, which, according to the accounts of Pytheas (q. v.), about 350 B.C. bought amber from the natives of the isle of 'Abalus,' and traded with the Greek colonies in S. Gaul. After this they settled on the Lower Elbe. They first appear in history after their migration to the Seine and alliance with the Cimbri, returning from Spain (103 B.C.). While the T. were proceeding to Italy along with the Keltic Ambrones, they were almost annihilated at Aquæ Sextæ by Marius (102), their king, Teutobod, being taken prisoner. See Müllenhof, *Deutsche Alterthumskunde* (vol. i. Berl. 1870).

Teuton'ic Knights', the last of the three great orders of religious knights which were founded in the Holy Land at the time of the Crusades, the two others being the Templars and the Knights of St. John. The full form of their title is the Order of the German (or Teutonic) Knights of the Hospital of St. Mary in Jerusalem; but they are often briefly designated as Kreuzherren or Knights of the Cross, and Marianer or Knights of St. Mary. It was at the siege of Acre in 1190 that the brotherhood took its rise under the patronage of Friedrich V., Duke of Swabia, as a brigade for the care of the sick and wounded, and it received papal sanction from Clement III. in 1191. The first master, Hermann (not Heinrich) Walpot of Bassenheim, built a church and hospital at Acre, and obtained from Pope Celestine the same privileges as were enjoyed by the two older orders; the third master, Hermann Barth, received considerable possessions in Hessia, and thus laid the basis of the German branch of the corporation; and under his great successor, Hermann of Salza, who was raised to the rank of prince of the empire, the wealth of the knights was enormously increased by donations of property in Austria, Thuringia, Treves, and elsewhere. The failure of the crusaders in Egypt turned the attention of the T. K. to Europe. At first they were invited by Andreas of Hungary to undertake the defence of the district of Burza in Transylvania against the Cumanians, but the king grew dissatisfied and expelled them again. The real field of their activity was destined to be in the N. On condition that they should be the bulwarks of Christendom against the still heathen Prussians, the country of Lobau and Kulm was bestowed upon them; and for the rest of their existence as a real confederation of warriors they were engaged in reclaiming the lands along the Baltic from the possession of Prussians, Poles, and Lithuanians. In 1237 they were strengthened by the incorporation of the Brethren of the Sword. On the loss of their possessions in Palestine by the fall of Acre in 1291, the central seat of their order was transferred to Venice, and in 1309, under the reign of the grandmaster Siegfried of Feuchtwangen, it was wisely removed to the castle of Marienburg, which had been founded in 1278. The purchase of the duchy of Pomerania, inclusive of Danzig, from the Markgrafs of Brandenburg in 1308, greatly advanced the prestige of the order, its wealth and influence continuing to increase during the following century. But in 1410 Ulrich of Jungingen, with an army of 80,000 men, suffered a terrible overthrow, in the battle of Tannenberg, at the hands of the Polish king Vratislav V., and from the blow thus struck the T. K. never recovered. Internal dissensions contributed to their decay, and at last, in 1525, Albrecht of Brandenburg, the grandmaster, not only agreed to recognise the superiority of the Polish crown over the Prussian territory of the order, but obtained from his new overlord the title of hereditary duke. It was in vain that the malcontents appealed to the empire, and secured the appointment of Walter of Kronberg to the office of grandmaster, and the removal of the seat of government to Mergentheim. The dissolution of the order was begun, and in the course of the century it rapidly advanced. In 1561 Gotthard of Kittler, the master of the Livonian province, surrendered Livonia to the King of Poland, and in the following year was rewarded with the title of Duke of Courland and Samgallen. The history of the T. K. had practically closed, for their German possessions were too small and scattered to secure them much political influence. The weak and wizened corporation was finally abolished in Germany by Napoleon in 1809; but it still exists with renovated vigour in Austria, where it received new statutes from Ferdinand I. in 1840, and has returned to the original task of taking care of the sick and wounded in war. A Netherland branch also still survives; for though it too was abolished by Napoleon, it was restored in 1815 by King William. The T. K. did invaluable service in the civilisation of N.-eastern Europe, for they not only knew how to subdue by the sword, but also how to discipline and educate the people under their sway. They founded cities, reclaimed much land from the sea and the wilderness, encouraged agriculture, suppressed piracy, and protected commerce. While they were at the height of their power they acted as the fathers of their subjects, and it was only when they were in sore straits themselves that they became reckless of the sufferings of others. The vast extent of the organisation rendered an elaborate system of subordination necessary. Every province was governed by a provincial master or commendator. Besides the grand master there were five great officials for the whole order—the grand commendator or treasurer, who also acted as vice grand master, the marshal-in-chief or head of the purely military department, the chief hospitaler or overseer of the sick, the chief master of the robes who looked after the supply of clothing, and the tressler or head of the financial department. There was summoned annually a general chapter of the order, and a special chapter in each province. See Voigt, *Geschichte des Deutschen Ritterordens* (Berl. 1857-59); Pfeiffer, *Deutsch Ordens Chronik* (Stutt. 1854), and Prutz, *Die Besitzungen des D. O. im Heiligen Lande* (Leip. 1877).

Teuton'ic Lan'guages, a subdivision of the great Indo-European or Aryan (q. v.) family of languages. The name Teutonic is derived from the Teutones, after whose conquest by Marius it came to be applied to all German-speaking people. Its origin is found in the Old High German *diot*, 'people, *duit-isc*, 'national,' the Old Eng. *theod* and *theodisc* (comp. Umbrian Lat. *tuticus*, from *tuta*, 'city'), of which the words *Deut-sch* and *Dutch* are modern forms. The T. L. are divided into three groups—(1) the Scandinavian (q. v.); (2) the Low German; (3) the High German (see GERMAN LANGUAGE). The Low German embraces Gothic (q. v.), the most primitive known Teutonic language, Platt-Deutsch (q. v.), Frisian (q. v.), Dutch (see NETHERLANDS), Flemish (q. v.), Old Saxon —spoken between the Rhine and Elbe, a specimen of which is extant in the *Heljand* (Old Eng. *Heiland*), '*Healer*' or 'Saviour,' a work of the 9th c.—and English (q. v.). See Jacob Grimm, *Deutsche Grammatik* (Gött. 1819 40); Max Müller's *Lectures* (1861-64); Schleicher, *Compendium der Vergleichenden Grammatik der Indo-German-Sprachen* (Weim. 1866); Helfenstein, *Comparative Grammar of the T. L.* (Lond. 1870).

Tewkes'bury, an old town of Gloucestershire, in the vale of Evesham, on the Avon, near its confluence with the Severn, 9 miles N.N.W. of Cheltenham by rail. It has a fine abbey church, founded by Robert Earl of Gloucester (died 1107), consecrated 1121, and restored 1875-77. The W. end and arches and the tower are in the Norman style of the period, but the pinnacles are regarded as later additions. T. has considerable trade in grain and live-stock, and the navigation hither has been improved of late years. Formerly noted for its mustard, T. now produces nails, hosiery, shoes, leather, &c. It returns one member to Parliament (two previous to 1867), and publishes two weekly newspapers. Pop. (1871) 5409. Although a place of great antiquity, T. is almost unknown in history before the foundation of the abbey. In its vicinity the Yorkists under Edward IV. and the Duke of Gloucester (afterwards Richard III.) gained a memorable victory over the Lancastrians, 4th May 1471. See Blunt's *T. Abbey* (Lond. 1877).

Tex'as (Ind. 'the hunting-ground'), a S.-western state of the American Union, more than twice the extent of the British Isles. Of very irregular outline, it is bounded N. by the Indian territory, from which it is partly separated by the Red River, on the E. by Louisiana and Arkansas, on the W. by the territory of New Mexico, in the S.E. by the Gulf of Mexico, and in the S. and S.W. by the Mexican republic, from which it is parted throughout by the Rio Grande. Area, 274,356 sq. miles; pop. (1870) 818,579,

of whom 564,700 were free coloured, and 724 Indians and Chinese. The state authorities estimated the pop. at 1,500,000 in 1875. T. is 800 miles in length from S.E. to N.W., and 750 in breadth, while its low, sandy coast-line, lined with sand-spits and lagoons, is nearly 400 miles long. The chief rivers, which all flow in a S.E. direction to the Gulf, are the Rio Grande, its affluent the Pecos, the Nueces, the Colorado, Brazos, Trinidad, and Sabine. The Red River leaves T. after following the northern boundary. The 'coast belt,' an alluvial strip from 40 to 60 miles wide, is partly barren waste, partly covered with thickets of cactus and chaparrals. Rich, rolling prairie extends further inland for upwards of 150 miles, covered here and there with forests of live-oak, pine, ash, elm, walnut, butternut, pecan, box, elder, and, towards the coast, magnolia, cypress, palmetto, &c. E. of Trinidad river T. is heavily timbered, but there are tracts cleared and cultivated, while the river-bottoms yield fine crops of cane, corn, cotton, &c. Beyond the prairie belt the land rises to about 1000 feet, has a rough broken surface, and affords excellent pasturage. Between the Colorado and Rio Grande there are many extensive sheepwalks and ranchos, where horses, mules, and cattle are raised in great numbers. In 1877 Captain King had 102,400 acres fenced in, and 50,000 head of cattle; to the W. of Corpus Cristo, Mr. Kennedy had an enclosed 'run' of 150,000 acres, containing a stock herd of 70,000. To the W. and N.W. the land rises to the *mesas* or arid plateaux of the Llano Estacado, where vegetation is scant and the only tree is the mesquite. Yet even here there is pasture enough for wild horses, buffaloes, &c. Further W. spurs of the Rocky Mountains enter T.—the Apache group, the Guadalupe Mountains, and other. The formations are chiefly Tertiary, Cretaceous, and Carboniferous; and the minerals comprise copper, iron, coal, galena, manganese, cobalt, nickel, bismuth, asphalt, gypsum, salt, saltpetre, antimony, potter's clay, mineral oils, soapstone, &c. The great bituminous coalfield, an outlying part of the Missouri field, has an area of 6000 sq. miles. The chief wild animals are the mustang, wolf, black bear, puma, jaguar, lynx, racoon, opossum, and peccary. The streams abound with fish, including black bass; and among the birds are the wild turkey, pheasant, quail, snipe, wild duck, vulture, pelican, heron, flamingo, and kingfisher. In 1875 there were 2,964,836 acres of improved land, and the value of live-stock (429,504 horses, 61,332 mules and asses, 3,182,904 cattle, 1,632,071 sheep, 1,202,445 hogs) was $38,888,734. The yield of wheat was 1,474,000 bushels; rye, 40,521; Indian corn, 28,016,000; oats, 1,118,000; barley, 63,000; sweet potatoes, 2,325,000; rice, 63,884 lbs.; tobacco, 59,706; cotton, 350,628 bales; wool, 1,251,318 lbs.; wine, 6216 gallons; cane molasses, 246,062 gallons; and honey, 275,164 lbs. The quality of cattle in T. is every year improving, and their price has nearly doubled since the exportation of beef to England began. Sheep-rearing is also on the increase, and of late many English and Scotch as well as American breeders have entered the business. The principal industries are lumbering, meat-packing, and cotton-making; and there are also coal and copper mines, smelting-furnaces, and salt-works. In 1875, T. had 1540 miles of railways; and in the year ending May 31, 1878, the T. and Pacific Railway brought into T. 5674 first-class passengers and 27,718 immigrants. Austin is the capital, and Galveston (q. v.) the chief seaport; larger towns yet are Houston and San Antonio. T. belonged to Mexico till 1835, when the settlers under Sam Houston (q. v.) formed it into an independent republic, which was defended successfully against Santa Anna (q. v.) in the battle of San Jacinto (21st April). It was voluntarily annexed to the United States in 1845, and its invasion by the Mexicans led to the war of 1846-47. In the Secession war it joined the Confederacy, and was the last state to surrender. It was under military command till 1869, and adopted a new constitution in 1876. See Baker's *History of T.* (New York 1873), and a Report on T., contributed to the *Times* of 3d January 1878.

Tex'el, an island of N. Holland, at the entrance to the Zuider Zee, is separated from the Helder by the Marsdiep, which is defended by a fort (Oude Schan). Area, 83 sq. miles; pop. (1876) 6260. It is partly girt with dykes, partly with dunes, and its rich pasture supports some 34,000 sheep, which yield, besides about 200,000 lbs. yearly of fine wool, the famous green cheese known as Texeler Schafkäse. Eijerland ('egg land') in the N. is visited by myriads of sea-fowl for the purpose of breeding. T. has two harbours. Along its coast have taken place many famous sea-fights.

Tezcu'co ('place of detention'), a lake of Mexico, the largest of four which cover a considerable part of the circular valley that contains the city of Mexico. Area, 77 sq. miles. It occasionally overflows its banks and inundates the streets of Mexico, which are only 3½ feet above its ordinary level. The town of T. stands on the shores of this lake 16 miles N.E. of Mexico. It is now much decayed, and its pop. is only about 5000.

Thackeray, William Makepeace, great-grandson of Archdeacon T., head-master of Harrow (1746-60), and grandson of a member of the E. Indian Council, was born at Calcutta, 12th August 1811. His father, Richmond T., also a civil servant, died in 1815, and two years later the boy was sent home to England; the ship touched at St. Helena, and he saw the Corsican ogre, who ate three sheep a day, and as many children as he could catch. At Charterhouse (1822-28) the battle and bravo sketches of T. ranked higher than those of his younger schoolmate Leech; at Trinity College, Cambridge, he was the friend of Tennyson, Kemble, John Sterling, and Monckton Milnes, and edited the motley, short-lived *Snob* (1829). Cambridge he left without a degree, and thinking to make art his calling, studied in 1831 at Weimar, 'the dear little Saxon town where Goethe lived,' anon at Rome, lastly at Paris under Bonington. Exchanging brush for pen, he furnished as editor the weekly *National Standard* (1833-34) with stories, verses, and woodcuts, published *Flore et Zephyr, Ballet Mythologique* (Lond. and Par. 1836), and sunk what was left out of Richmond T.'s savings in his stepfather's daily, the *Constitutional and Public Ledger* (1836-37). This loss and his marriage with a dowerless wife made letters thenceforth a hard necessity, and besides writing for the *Examiner, Times*, and *Westminster*, he contributed to *Fraser* (1837-44) the *Yellowplush Correspondence, Catherine, Shabby Genteel Story* (broken off by a heavy domestic sorrow), *Great Hoggarty Diamond, Fitz Boodle Papers, Little Travels*, and *Barry Lyndon*. The *Bedford Row Conspiracy* and *Major Gahagan* appeared in the *New Monthly* (1838-40), in *Punch* (1841-50) the *Ballads of Policeman X, Snob Papers, Jeames's Diary*, and *Novels by Eminent Hands*; while the *Paris Sketch-Book* (1840), *Irish Sketch-Book* (1843), *Journey from Cornhill to Grand Cairo* (1846), and *Mrs. Perkins's Ball* (Christmas 1846), were issued as independent works. Now we can mark the steady growth of T.'s powers, and even in 1841 Sterling pronounced his *Hoggarty Diamond* as good as anything in Fielding or Goldsmith; but the world at large was just inquiring who 'Michael Angelo Titmarsh' might be, when *Vanity Fair*, rejected of magazines, came forth in monthly parts (1847-48), and before its close established its author's name. His brilliant success in London, the provinces, and America as lecturer on the *English Humorists of the 18th c.* (1851-52), and the *Four Georges* (1855-56), his defeat at the Oxford elections as Cardwell's Radical opponent (1857), the starting and editorship of the *Cornhill Magazine* (1860-62)—these were the chief events of T.'s prosperous years. Their fruits were five more of his *Christmas Books* (1847-55), *Pendennis* (1850), *Esmond* (1852), *The Newcomes* (1855), *Virginians* (1859), *Lovel the Widower* (1861), *Philip* (1862), *Roundabout Papers* (1862), and *Denis Duval*, the fragment written, like its three predecessors, for the *Cornhill's* pages. A rich man now, he had lately removed to his favourite 'Old Court Suburb' near Kensington Palace, when on the Christmas Eve of 1863 the Master at midnight called, and T. answered *Adsum*. He is buried at Kensal Green; Poets' Corner contains his bust. The sterling merit of T.'s novels lies in their absolute truth to nature. He wrote of nothing that he did not know, and in the 'Grey Friars' and 'Oxbridge' of Clive and Pendennis we see his own school and university, in 'Pumpernickel' the Weimar court, in 'Clavering' his stepfather's Devonshire residence, Ottery St. Mary; just as his pictures of Anglo-Indian and literary life, his delineations of last century presented in *Esmond* and the *Virginians*, in the *Lectures* and *Denis Duval*, are the outcome of keen personal observation or of loving, laborious study. His heroes and heroines are often weak, his scoundrels never without redeeming qualities, the reason being that T. recognised no race of Admirable Creightons, had met no villains wholly villanous. Of plot there is just so much or little as in everyday life; the events and characters evolve themselves. The reappearance of Beatrix, beautiful as heartless, as the Baroness

Bernstein, fat and worldly, is perfectly consistent and intelligible; while Esmond's marriage with Lady Castlewood is justified by the author's answer to a friend's remonstrance: 'I didn't make him do it; they did it themselves.' So true himself, he hated all lying, pretence, and shams; and snobbery, alike of high and low, was mirrored by him in all its loathliness. And we, offended by the too-faithful mirror, have likened it to the hob-goblins in Andersen's story, and branded T. with the name of cynic. He a cynic, the creator of Esmond and Warrington, of Helen and Colonel Newcome, the tender monitor of Philip and Pendennis, of all his brother men! we his accusers, fearing ourselves the charge—'Thou art the man, not Steyne, or Becky, or Barnes'! Interpret these books by their author's life, its ceaseless charity and boundless faith, and he stands revealed as the great Humorist Preacher, in genius equal, in largeness of soul superior, to Fielding. His drawings, too hasty to be faultless, but vigorous always, often beautiful, have been in part collected by his daughter in the *Orphan of Pimlico and Other Sketches* (Lond. 1876); for his Life we have only brief monographs by Hannay (Lond. 1864) and Theodore Taylor (Lond. 1864), with articles in the *North British* (February 1864), *Edinburgh* (January 1873), &c. A Life, however, by Anthony Trollope, is announced for publication in the *Men of Letters* series (February 1879).—**Anne Isabella T.**, born about 1839, ranks high among living novelists by her contributions to the *Cornhill.* These, as republished, include the *Story of Elizabeth* (1863), *Village on the Cliff* (1867), *Five Old Friends and a Young Prince* (1868), *To Esther, and Other Sketches* (1869), *Old Kensington* (1873), *Bluebeard's Keys* (1874), *Toilers and Spinsters* (1874), and *Miss Angel* (1875), the last being founded on Angelica Kaufmann's life. Tender and harmonious, her stories—and specially the recasts of world-old folktales—remind one of Birket Foster's pictures, with their exquisite backgrounds; like her father's, they depend not for interest on intricate plot, and through them flows a quiet undercurrent of subtle, subjective thought.

Thalamiflo'ræ, a subdivision of dicotyledonous plants, including all those orders in which the majority of genera have distinct petals, inserted with the stamens on the receptacle under or around the ovary.

Thalassicollida, a group of *Protozoa* (q. v.) belonging to the order *Radiolaria* (q. v.), and closely allied to Foraminifera and other *Rhizopoda*. They have structureless cysts, and give off processes resembling rays, and which may unite so as to form a network. The T. exist as simple or compound organisms.

Thal'berg, Sigismund, a composer and a great master of the pianoforte, was born at Geneva, January 7, 1812. He studied under Hummel at Vienna, Pixis at Paris, and Moscheles at London, after which he devoted himself entirely to the pianoforte. Probably no performer ever produced such orchestra-like effects as characterised T.'s style of playing. He had extraordinary power in his wrists and flexibility in his fingers, which enabled him to produce results equal to those obtained by four ordinary hands, and his style was remarkable for brilliancy and elasticity. He composed numerous compositions for the pianoforte, the most popular of which is perhaps his well-known variations on *Home, Sweet Home.* He died 27th April 1871. T. married a daughter of Lablache, and his own daughter, Mademoiselle Zare T., has appeared with success during the last few seasons at the Royal Italian Opera, Covent Garden.

Thalei'a (Gr. 'blooming'), one of the nine Muses (q. v.), who in later times was regarded as the patroness of comedy and banquets.

Thal'er, a German coin worth about three shillings of English money. It is going out of use. See DOLLAR, and MARK.

Tha'les, of Miletus, an early Greek philosopher, and one of the Seven Wise Men (q.v.), was born about 640 and died about 546 B.C. His theory of the universe was—Water is the cause and first or original ground of all things; everything comes from it; to it everything returns. T. was the first Greek who, as Aristotle remarked, sought a reasoned explanation of the universe. He was celebrated in antiquity, not only as a philosopher, but as an astronomer and politician.

Thall'ium (Tl = 204), a metallic element, was discovered by Crookes in 1861. While examining the spectrum obtained by holding in the flame of a Bunsen burner the residue of the iron pyrites which are deposited in the flues of a sulphuric-acid chamber, he observed a green line which was not referable to any known substance, and which he then traced to its source. T. occurs most abundantly in copper and iron pyrites, and is a soft nearly white metal tarnishing quickly in the air. It closely resembles lead in its physical properties, melts at 294° C., and volatilises at a red heat. It forms two oxides the thallous (Tl_2O) and thallic (Tl_2O_3), the former of which is very soluble in water, is distinctly alkaline, and reacts in the same manner as caustic potash. The thallic oxide is a dark-red insoluble powder, and is reduced by heats to thallous oxide. Both these oxides give rise to a series of salts, the thallous salts being the more stable. The salts of T., like those of lead, are poisonous.

Thallo'genous Plants, Thall'ogens, or **Thall'ophy'tes**, are names applied to leafless cellular cryptogams, *i.e.*, to plants which have no flowers, no leaves, no axis, no vascular tissue, but are constructed of cells only. To this division belong Algæ, Fungi, and Lichens. It is impossible to draw strict lines of demarcation between these three classes. Hepaticæ (q. v.) form a transition from T. to Acrogens (q. v.).

Thall'us (Gr. 'a frond'), in botany, implies the fusion of root, stem, and leaves into one general mass. The term is used to express that part of Thallogenous Plants (q. v.) immediately bearing the fructification, but is more especially applied to the whole vegetative system of Lichens (q. v.), in which three types of structure of T. may be distinguished—the stratified, the pictorial, and the gelatinous. The T. in fungi consists of two principal parts, the mycelium and the receptacle or stroma, the latter being as a rule the conspicuous part, and in the mushroom, for instance, popularly regarded as the whole fungus. In ferns and some mosses the spore on germinating gives rise to a thalloid leaf-like structure called the *prothallium* or pro-embryo.

Thames (Celtic *Tamh*, 'quiet'), the longest river in England, and perhaps the most important and picturesque in Great Britain, has a length of 210 miles, and a drainage area of over 6000 sq. miles. It is formed at Lechlade in Gloucestershire, by the confluence of the Churn (with its tributaries the T. Head and Key), Leach, Colne, &c., from the Cotswold Hills, and the Cole from the S. After flowing E. for 12 miles, it takes a northerly bend, receiving on the left the Windrush and Evenlode. Turning to the S. E. it passes Oxford, and is joined by the Cherwell, the Ock (at Abingdon), the Thame and the Kennet (at Reading), then keeping more directly to the E., by the Loddon, Wey, Mole, Wandle, Darrent, and Medway from the S., and by the Coln, Brent, New River, Lea, and Roding from the N. The chief places on its lower course are Windsor, Eton, Richmond, London, Greenwich, Woolwich, and Gravesend, below which the river expands into an estuary, widening till it enters the North Sea at the Nore (q.v.), opposite Sheerness. Alone of the larger English rivers, the T. forms nearly throughout its course a boundary between counties—Wilts, Oxford, Buckingham, Middlesex, and Essex; Kent, Surrey, and Berks. It is tidal to Teddington, 19 miles above London Bridge, and at this point 380,000,000 gallons flow over the weir every 24 hours. At high tide the T. is 250 feet wide here, while at London Bridge, 45 miles from the Nore, it is 800 feet wide and 30 feet deep. Its width at Woolwich is 490 yards, at Gravesend 800 yards, and at the Nore Light 6 miles. It is navigable for barges to Lechlade (200 miles), for ships of 800 tons to St. Catharine's Docks, near London Bridge, and for vessels of 1400 tons to Blackwall, below the Isle of Dogs. At London (q. v.) the T. is crossed by 15 bridges, and it is lined by magnificent Embankments, extending on the N. from Blackfriars to Westminster, and from Albert Bridge to Chelsea Hospital; and on the S. from Westminster to Lambeth. These Embankments, together with the splendid new approaches from Charing Cross and the City, were constructed at a cost of over £4,000,000. Although the T. does not form a true delta, it carries down large quantities of mud, which in its lower 'reaches' or bends give it a proverbial turpidity. This mud is systematically dredged and removed to prevent obstruction. See Mrs. Hall's *Book of the T.* (Lond. 1869), and Huxley's *Physiography* (Lond. 1877).

Thane, or **Thegn** (Old Eng. *thegnian*, 'to serve;' *cf.* Ger. *dienen*), the title originally of the servants of kings and ealdormen, who, as a new kind of nobility attached to their order, gradually superseded the older eorls. The 'dish-T.', 'horse-T.', and 'bower-T.' became great officers of state; the name of T.

was used synonymously with 'gentle,' and with the growth of the kingly power the king's thegns rose to the highest rank of gentry, those of ealdormen and bishops forming an inferior class. In its turn the native thegnhood was thrust down at the Conquest to a secondary place, and the title was displaced by those of tenant-in-chief, of knight, and gentleman. See NOBILITY; also Freeman's *Comparative Politics* (1873), and *History of the Norman Conquest* (1870-76).

Than'et, the N.E. portion of the county of Kent, England, is separated from the rest of the county by the Stour, and is bounded on the N. and E. by the German Ocean. The length is 10 miles, its breadth increasing from 3 in the W. to 8 in the E. The geological formations are mostly recent; chalk abounds, and forms cliffs around the coast. Of the 26,600 acres 93 per cent. are under cultivation. Margate and Westgate on the N., Ramsgate and Broadstairs on the E., are favourite watering-places with the Londoners. The N.E. corner forms the N. Foreland, with a famous lighthouse. Pop. (1871) 42,129. A few marshes are all that now represent the Wantsum or waterway which at one time separated T. from the mainland. It is still easy to discover, in the misty level of Minster Marsh, traces of the channel by which the first English invaders of Britain approached the gravel-spit of Ebbsfleet.

Thann, a town of Elsass-Lothringen, on the Thur, at the entrance of the St. Amarinthal, 11½ miles N.W. of Mulhausen by rail. The church of St. Theobald (1455-1516), with an elegant pierced spire 266 feet high, is richly and tastefully decorated. T. contains several thriving cotton and silk factories, machine-works, foundries, &c. Pop. (1875) 7532.

Tha'sos, a Turkish island in the Ægean Sea, off the coast of Thrace, 3½ miles from the mouth of the Karasu or Mesta. Area 85 sq. miles; pop. about 7000, mostly Greeks. It is covered with mountains, the highest of which, Mount Ips-ario, rises to a height of 3428 feet. Cultivated spots of extraordinary fertility occur near the seashore, and wine, oil, honey, maize, and timber are largely exported. In ancient times productive gold mines were worked in the island.

The'a. See TEA.

The'atines were a religious order which was founded in the Roman Catholic Church in the 16th c., in the attempt to introduce among the regular clergy that reform which was universally felt to be deeply needed in all the institutions of the hierarchy, of which feeling the Protestant Reformation was only a peculiar outcome. The society was founded by John Peter Caraffa, afterwards Pope Paul IV., then Bishop of Chieti or Theate (whence the name T.), and Cajetan de Thiene, who, along with other two friends, assumed the usual vows of poverty, chastity, and obedience, September 14, 1524. Being properly only regular clergy with the vows of monks, they did not adopt any peculiar dress. Their intention was to establish a seminary for the priesthood, and their prescribed clerical duties were preaching, administration of the sacraments, and care of the sick. As the founders were of noble birth, the T. came to be considered the order of priests peculiar to the nobility. The order soon spread over Italy, then into Spain, Poland, and Germany, and in the 17th c. into France. See Helyot, *Hist. des Ordres Religieuses*.

The'atre (Gr. *theatron*, from *theaomai* = 'I see') means literally any building used for purposes of public exhibition, but is now commonly restricted to buildings approaching more or less nearly to a semicircular form, whether used for lectures, anatomical or chemical demonstrations, or dramatic performances. In general conversation the word is applied almost exclusively to the last-mentioned class. The T. of the Greeks and Romans differed in many important respects from the modern T. The nature of the Greek drama (see DRAMA) as a universally popular, semi-religious institution, led to the construction of theatres immensely larger than any which have been attempted in modern times. It is calculated that the T. at Epidaurus contained seats for 16,000 spectators, that of Syracuse for 22,000, and that of Megalopolis for 44,000. The enormous size of the auditoriums, combined with the tendencies derived from its religious origin, gave to the Greek tragedy a statuesque and almost operatic character, which reacted on the form and arrangements of the stage, making it much simpler than the complicated structure of elaborate mechanism which the modern drama demands. The Greek T., then, was composed of three parts—the *theatron* or *koilon* (*i.e.*, the auditorium); the *orchestra*, analogous in position to our stalls and pit, but occupied not by spectators but by the *choros*; and the *skēnē* or stage, where the actual performances were conducted. The *theatron* was composed of concentric rows of semicircular stone seats rising above each other like a flight of stairs. In some of the Greek theatres the arc was larger than a semicircle. It was never roofed, but in some of the later theatres arrangements were made by which an awning could be drawn over in case of need. The Greek T. was almost invariably placed in some natural hollow, where the architect was assisted by the form of the ground. The Romans, on the other hand, generally built their theatres on flat ground. An inner semicircle concentric with the curve of the *theatron*, and making, as it were, the bottom of the basin, formed the *orchestra*. In it, probably at the exact centre of the whole building, was situated the *thymelē*, or altar of Dionysus. In it, too, were the 'Charonic steps' by which spirits ascended. Two *parodoi* or passages, one on each side, led into the *orchestra* from the exterior of the building, and separated the *skēnē* from the *theatron*. By these, messengers and persons supposed to come from abroad arrived, and ascended the *skēnē* from the *orchestra* by means of steps. In the Roman theatres the spectators encroached upon the *orchestra*, which became the place of honour. The *skēnē* in the Greek T. never occupied the full diameter of the semicircle, as it did in the modified Roman form, but left open a space at each side through which the spectators could command a view of the surrounding scenery, which was always taken into account in the selection of a site. The *skēnē* consisted of a flat two or three storied building, with a wing projecting at each side, and thus enclosing an open platform, the *logeion* (Lat. *pulpitum*) or stage proper, raised considerably above the *orchestra*. The *logeion* and its back wall, which was pierced by three entrance-doors, were called the *proskēnion*, and the wings, in each of which there was also an entrance-door, were called *paraskēnia*, forming the green-rooms, dressing-rooms, property-rooms, &c., of the T. In some Greek and most Roman theatres the stage could be screened by a curtain, which, however, rose from below instead of falling from above the *proskēnion*. Though there was little need for changes of scene in the Greek drama, the *skēnē* probably afforded greater facilities for variety of decoration than is sometimes supposed. At either side of the *logeion* was a three-sided revolving pillar—a prism—on each face of which was represented a different decoration, so that provision was made for three different 'wings,' as they would be called in a modern T. The *proskēnion*, too, could be made to represent a palace, temple, or other building at will, and the machinery by which the *Deus ex machinâ* made his descent, or the hero was wafted to Olympus, though its construction has not been thoroughly ascertained, must have been elaborate. Acoustic properties were necessarily thoroughly studied, and the resonance given to the actors' voices by their brazen masks was assisted by arrangements which, in the absence of a precise knowledge of their nature, we may call sounding-boards, fixed in the seats throughout the auditorium. The theatres at Aspendus, Egesta, and Patara are among the finest existing examples of the Greek T., and those of Orange in the S. of France, of Pompeii, and of Herculaneum, are perhaps the best examples of the Roman T. See Genelli's *Das T. zu Athen* (Ber. 1818); Ferrario's *Storia e Descrizione de principali Teatri antichi e moderni* (Milan 1830); Donaldson's *T. of the Greeks* (7th ed. Lond. 1860); Geppert's *Die Altgriechische Bühne* (Leip. 1843); Schonborn's *Die Skene der Hellenen* (Berl. 1861); Becker's *Charicles* (2d ed. Lond. 1854); Strack's *Das Altgriechische Theatergebäude* (Potsdam 1843); and Arnold's *Altrömische Theatergebäude* (Leip. 1873).

Throughout the Middle Ages, the drama, such as it was, had for its sole machinery two or three storied scaffolds erected in cathedrals, monasteries, or baronial halls, to represent heaven, earth, and the regions below, as required by the popular mysteries and moralities of the day. With the revival of learning came a revival of the drama, and specially-constructed buildings began to be set apart for dramatic representations. The earliest Italian theatres—those by Bramante in the Vatican, by Palladio at Vicenza (1580), and by Alcotti at Parma (1618)—were designed on the ancient model, though on a much smaller scale. In England, France, and Germany, the earliest dramatic representations, properly so called, took place either in booths, or in

tennis-courts and inn-yards. The form of the theatres with which we are now familiar, with from two to five or six tiers of seats, was perhaps suggested by the old inn-courtyard with its galleries. To give an idea of a T. of Shakespeare's time we cannot do better than condense the description given by Mr. W. Lloyd of the Globe in Bankside :—'The internal galleries were protected by a roof of which the eaves sloped outwards only, while the central pit or yard was open to the sky, and the portion of the octagon that was occupied by the stage and tiring-rooms was covered. The foppish custom of privileged spectators sitting on the stage on stools, with pages attendant, was a source of standing annoyance to the general audience. The curtains in front of the stage ran upon a rod and opened in the centre, and the stage itself seems to have had an enclosure or arras, answering the purpose of our side-scenes; towards the back, where they were called traverses, they could be drawn and undrawn as required. In the centre of the stage at the back was a secondary stage, more or less permanent. The break of level was supposed to account for any distance of perspective, and thus a double action might proceed on the stage at once. [This secondary stage formed indifferently the ramparts of a castle or the heights of a battle-field, Mark Antony's rostrum, Juliet's balcony, or the stage for Hamlet's players.] In the way of scenery, the utmost that was attempted seems to have been to put such fixed properties on and about the stage as would suggest the scene required. Tombs, rocks, hell-mouths, steeples, beacons, and trees are found in lists of properties. There were devices for counterfeiting thunder and lightning, for exhibiting the sun breaking through a cloud, &c. Graves and trap-doors, ascents to and descents from heaven, were also provided for. The stage was strewn with rushes, and on occasion, by excess of refinement, it was matted. The band of eight or ten performers is supposed to have sat in an upper balcony over what is now called the stage-box.' It remains to be said that changes of scene were generally effected simply by putting up a placard announcing what the stage was supposed to represent; that the dresses were rich and often extravagant; and that until the Restoration female parts were uniformly taken by boys or young men.

Movable scenery, first introduced in Italy by Balthazar Sienna in 1553, and to some extent perfected by Bibbiena in Italy so early as 1657, led to a revolution alike in dramatic literature and in theatrical construction. Inigo Jones, in the masques which he invented along with Jonson, Carew, and Davenant, seems to have carried stage mechanism to considerable perfection; but it was not until after the Restoration that movable scenery, as we at present know it, was practically utilised upon the stage. Since then, scenic art has become more and more elaborate, until at several periods, and perhaps never more than at the present day, it has threatened to swallow up dramatic art and to make of the T. an exaggerated panorama. Theatrical construction has attracted the attention of almost all the greatest architects of the last two centuries, but except in details of comfort it can scarcely be said that much progress has been made since the first elliptical or horse-shoe theatres with ascending tiers were constructed in Italy early in the 17th c. The desiderata of a perfect T. are four in number—(1) That the whole stage shall be seen from all parts of the auditorium; (2) that what passes on the stage shall be distinctly heard throughout the auditorium; (3) that the ventilation of the auditorium shall be perfect; (4) that there shall be adequate provision for comfortable ingress and rapid egress. In no single T., it is probable, have all these conditions been fulfilled. An elongated form of auditorium is said to be the most advantageous acoustically speaking, and it has therefore been generally adopted in opera-houses. On the other hand, there can be no doubt that, for seeing, a form approaching as nearly as possible to a semicircle is the best, but this can, of course, only be adopted in moderate-sized theatres, where the width of the stage may bear a large proportion to the curve of the auditorium. The theatres and opera-houses of the Continent, where the drama is state-supported, stand, as a rule, on open spaces of ground, and have handsome corridors, staircases, crush-rooms, *foyers*, *loggias*, &c., while their external architecture is often extremely handsome. In England, on the other hand, theatres are generally squeezed in between the houses of crowded thoroughfares upon small plots of extremely valuable ground, greatly to the detriment not only of their beauty but of their convenience and safety.

The stage of a great modern T. is a huge piece of mechanism, inconceivable to those who have not seen it, incomprehensible to those who have not practically studied it. Let us imagine ourselves standing close to the *footlights*, now generally sunk in a deep groove and provided with movable screens of different coloured glass so as to represent moonlight and other atmospheric effects. The curtain is up, and we are looking towards the back of the great sloping platform. It may be that almost the whole stage is shut off by a *flat* scene, placed in the foremost grooves, or by a *cloth*, a great piece of painted canvas let down from above. In the angle of the proscenium, probably to our right, sits the *prompter* at his little table, his *scene-plot* before him, and his apparatus of bells and gas-regulating cranks close at his hand. The opposite side of the stage is called the *O P*, and both are lighted by spiral lines of gas jets called *gas wings* or *ladders*, while the rows of gas jets suspended above the proscenium, and lighting the stage from above as the footlights do from below, are called the *gas battens*. At a sound of the prompter's bell the cloth rises or the flat is slid off, and we find behind it a great *set-scene*. It may be a carpeted room, with walls, doors, windows, handsome furniture, a modern fire-place, a painted ceiling, &c., as complete and apparently as real as in the most luxurious dwelling-house; or it may be a landscape, the background filled up with a great painted *frame*, and the sides occupied by narrow scenes called *wings*, representing trees, houses, &c., while the top of the stage is draped with slips of canvas called *soffits* and *borders*, which may either represent the sky or a mass of overhanging foliage. Looking up, we can see the scene-shifters and gas-men among their wildernesses of ropes and pullies in the great lateral galleries called *flies*, but we cannot see the *barrel loft* in which are placed the drums and windlasses by which the curtains, cloths, and heavy pieces of scenery are worked. The stage, we may note, is covered with marks which show the situation of the *square traps* and *star-traps* by which performers can descend into regions below—technically the *well*—or be shot up from the depths by means of an elaborate system of weights and pulleys. Whole pieces of scenery, too, can be raised and lowered through the stage by means of the *bridges* working in great transverse openings. If we penetrate behind the frame at the back we shall probably find ourselves in the *scene dock*, or place for storing scenery when not in use. Above this in many theatres is the *painting room*, the domain of the scenic artist, while on every side is a labyrinth of dressing-rooms, property-rooms, and offices of every description up to the green-room and the sanctum of the manager himself. The reader who wishes to be initiated into all the mysteries of scenic effect in their most recent developments may study M. Moynet's elaborate treatise, *L'Envers du T.*, *Machines et Décorations* (Par. 1875).

Among the most famous, architecturally speaking, of Continental theatres are the San Carlo at Naples, the Scala at Milan, the Fenice at Venice, the Vienna and Berlin opera-houses, the court theatres of München and Dresden, the Town T. of Frankfurt, the Royal T. of Copenhagen, and the Bourdeaux T. Unquestionably the most magnificent T. the world has ever seen is the Nouvel Opéra of Paris, on which over a million pounds have been lavished. It covers 2·65 acres of ground, while Covent Garden covers only 0·70, La Scala and the San Carlo 0·90 each, and the Carlo Felice, Genoa, 1 acre. On the other hand, its auditorium will only seat 2156 persons, while Covent Garden seats 2500, La Scala and the San Carlo 3000 each, and Drury Lane 3060. Its artistic merits have been severely criticised, but of its gorgeousness there can be no doubt. A novelty in theatrical construction is the great Opera-T. at Bayreuth, built (1877) under the direction of the composer Wagner, specially for the performance of his operas. The scheme for a great National Opera House in London has apparently fallen through, as was indeed only to be expected of such a gigantic private enterprise. The following is a list of some of the principal theatres which have been erected in London since the beginning of the English drama in the reign of Elizabeth :—The T. in Shoreditch (1576-1598); the Curtain, also in Shoreditch (1577-1623); the Blackfriars* (1576-1647); Paris Garden, Southwark, also used for bear-baiting (1544-1647); the Whitefriars (1580-1612), rebuilt as the Salisbury Court T. (1629), called in 1660 the Dorset Court T.;

* Some very recent researches by Mr. Halliwell-Phillips tend to show that the Blackfriars T. was not founded until several years later than the date given above.

the Fortune, in Golden Lane (built 1599, burnt 1621, rebuilt 1623, pulled down 1661); the Globe (1593–1647, burnt 1613), in Bankside (where were also the Rose, Hope, Swan, and Newington Butts Theatres); the Cockpit or Phœnix in Drury Lane (1616–1662); Drury Lane T. (opened 1663, burnt 1672, rebuilt by Sir Christopher Wren 1674, again rebuilt 1794, burnt 1809, rebuilt by Wyatt 1812); the Haymarket T. (built 1702, rebuilt 1767, again rebuilt 1821); Covent Garden T. (opened 1732, burnt 1808, again burnt 1856, rebuilt by Barry 1858); Italian Opera House, Haymarket (opened 1705, burnt 1789, again burnt 1867, reopened as Her Majesty's T. 1878); Lyceum T. (built as English Opera House 1795, burnt 1830, rebuilt 1834), Adelphi T. (1806), Olympic T. (1806, burnt 1849), Strand (1831), Princess's T. (1840), Royalty T. (1863), Prince of Wales T. (1865), Globe T. (1868), Gaiety T. (1868), Charing Cross T., now Folly T. (1869), Vaudeville T. (1870), Court T. (1871), Criterion T. (1874). London possesses in all (1879) 57 theatres capable of seating 126,100 persons, but among the largest of these are the Transpontine and East-End theatres, where melodrama and pantomime furnish almost the whole repertoire. The first T. in Dublin was built in 1635, and the first Edinburgh T. in 1672. The theatres of many provincial towns—such as Liverpool, Manchester, Birmingham, and Glasgow—now rival the metropolitan houses both in size and splendour of decoration. There has of late years been a marked revival of interest in theatrical amusements on the part of the British public, accompanied by an improvement, slight, but still noticeable, in dramatic art itself. Still the state of things cannot be regarded as in any respect satisfactory. Public taste is undoubtedly low, and it will necessarily remain so as long as there is no single T. which can afford, for however short a time, to disregard it, or rather to attempt to raise it. We have no school of dramatic training. Our actors pick up their professional education at hap-hazard. The preference of the public too often tempts them to follow the worst rather than the best models. The system of long runs seems carefully calculated to ruin even the most promising artists. And finally the conditions of dramatic enterprise are such that our native playwrights have scarcely a chance to develop their talents, and the stage is overrun with adaptations from the French, in which unquestionable dramatic skill is too often combined with very questionable morality. The proposal to remedy this state of affairs by means of an endowed T.—whether endowed by Government or by private generosity—is generally met with ridicule, and is certainly not likely to be soon adopted. In it, however, lies the sole remedy for the evil. If it is impracticable, the evil is irremediable. The immeasurable superiority of French acting—a superiority which no one disputes—is often attributed to a greater natural aptitude for dramatic art on the part of the French as a people. The nation which can set Garrick, Kean, and Mrs. Siddons against Lekain, Talma, and Rachel, should be slow to admit any such natural advantage. A more rational explanation lies ready to hand in the fact that the French possess a T.—the Théâtre Français—which is, and has been for nearly two centuries, independent of immediate popular favour, which can afford to educate public taste, which provides for dramatic aspirants adequate and systematic training, which attracts to itself the very highest dramatic talent of the country by assuring to its *sociétaires* a handsome competence while at work and a handsome pension on retirement, and which affords to the other theatres of Paris a standard of dramatic excellence. The Comédie Française is, in fact, financially so successful that it costs the Government very little, but it is only by being able to support temporary pecuniary failure that it or any other T. can ensure permanent artistic success. To establish in England a T. precisely on the model of the Maison de Molière, would of course be impossible, but in some more or less similar institution lies the only chance for a revival of true dramatic excellence. We have no lack of talent either among authors or actors, but it is frittered away in catchpenny enterprises. The manager of a T. is too often possessed of about as much taste and culture as his own scene-shifters. His sole desire is to obtain an immediate return for his capital. He buys pieces and engages actors who will please the mob. While the causes of this state of things remain untouched, no real and abiding improvement can be hoped for.

Theatrical literature is of almost unlimited extent. On the construction of theatres see Ferrario's work already mentioned; Wyatt's *Observations on the Principles of Design for a T.* (Lond. 1811); the *Transactions of the Royal Institute of British Architects for* 1860 and 1864; a series of papers by Percy Fitzgerald in the *Art Journal* for 1876; E. M. Shaw's *Fires in Theatres* (Lond. 1876); E. Trélat's *Le Théâtre et l'Architecte* (Par. 1860); C. Garnier's *Le Théâtre* (Par. 1871); C. Nuitter's *Le Nouvel Opéra* (Par. 1875), condensed in *Scribner's Magazine* for the same year. On theatrical history in general see Riccoboni's *General History of the Stage* (Lond. 1754); Dunlop's *Life of G. F. Cooke* (Lond. 1815); Collier's *History of Dramatic Poetry* (Lond. 1831); Geneste's *History of the English Stage* (10 vols. Bath 1832); Mrs. Mathews' *Memoirs of C. Mathews, Comedian* (Lond. 1839; new ed. 1860); Luccas's *Histoire Philosophique et Littéraire du Théâtre-Français* (Par. 1847-63); Ricord's *Fastes de la Comédie Française* (Par. 1821); E. Devrient's *Geschichte der Deutschen Schauspielkunst* (Leip. 1848-61); P. Fitzgerald's *Life of David Garrick* (Lond. 1868); the same author's *Kembles* (Lond. 1871), *Principles of Comedy and Dramatic Effect* (Lond. 1870), and *Romance of the English Stage* (Lond. 1874); Dr. Doran's *Their Majesties' Servants* (2d ed. Lond. 1865); C. M. Young's *Memoir* (Lond. 1871); Planché's *Recollections and Reflections* (Lond. 1872); *Macready's Reminiscences*, edited by Sir F. Pollock (Lond. 1875); G. H. Lewes' *Actors and Acting* (Lond. 1875); Dutton Cook's *A Book of the Play* (Lond. 1876); H. Barton Baker's *Our Old Actors* (Lond. 1878).

Laws as to Theatres.—In the United Kingdom, 6 and 7 Vic., c. 68, provides that no house shall be kept for the performance of stage plays without authority by letters patent, or by license of the lord chamberlain, or of the justices of the peace. The lord chamberlain and the justices, within their jurisdictions, may suspend any license in case of riot or misbehaviour, or they may order the theatres to be closed on any public occasion. No new play, or old play altered, to be acted or recited till seven days after copies have been sent to the lord chamberlain with a fee not exceeding two guineas. The lord chamberlain may disallow the whole of the play or part of it. Infraction of his order subjects the offender to a penalty of £50, and the license of the theatre in which the offence is committed becomes void.

Thebai'a, or **Thebaine',** one of the active principles of Opium (q. v.), produces in all the lower animals powerful convulsions resembling those resulting from strychnine. T. has been employed in physiological experiments only.

Thebes (Gr. *Thebai*), the chief city, at least in historical times, of Boetia, was situated in the southern part of the country nearly midway between the Corinthian Gulf and the Euboean Sea, at the foot of Mount Teumessus, which rises about 150 feet above the plain, and between the two streams Ismenus and Dirce. Owing to the total destruction of T. by Alexander, the various localities are very difficult of identification, though the site itself is still occupied by the village of Thivi. The plan given by Forchhammer divides the city into two parts, a W. and E., separated by the little stream Strophia, the W. or upper part containing the Cadmeia or citadel on the S. and the Agora on the N., while the E. or lower city had the Ismenus on the S. and the Ampheion on the N. Of the celebrated seven gates he places the Homoloides, Electra, and Hypsistæ on the S., the Krenaiai on the W. between the Citadel and the Agora, and the others on the N. With these points fixed, there is no further difficulty in identifying all the buildings mentioned by Pausanias (ix. 8-25). T. is peculiar among Grecian cities, in that, though only for one brief period rising above the rank of third in importance, she occupies as prominent a position in the legendary as in the historical portions of the annals of the country, while her traditional connection with Phœnicia has of late turned the eyes of scholars to her with a new interest. Of her legendary heroes, Cadmus, Amphion, and Œdipus with his fated house are the most celebrated; in Greek history none surpass in greatness of achievement or nobility of character Epaminondas and Pelopidas. For the part played by T. in the general history of Greece, see *Hellas*. Besides the histories of Thirlwall, Grote, and Curtius, see Sankey's *Spartan and Theban Supremacies* (Lond. 1877); and for topography, Leake, *Northern Greece*; Ulrichs, in *Abhandl. der Bayer. Akad.* for 1841; and Forchhammer, *Topographia Thebarum Heptapylarum* (Kiliæ 1854).

Thebes (the *Taabe* of the hieroglyphics, *No* or *No-Ammon* of the Scriptures, and *Diospolis* of classic writers), the former

capital of Upper Egypt, extended along both sides of the Nile over a plain some 12 miles square, in lat. 25° 41′ N. Of unknown antiquity, it reached its zenith under the 18th dynasty, and for nigh eight centuries continued to flourish (1600–800 B.C.), its decay being hastened by the rise of Memphis. Cambyses sacked it in 525, and Ptolemy Lathyrus in 86 B.C., but its ruins still attest its former grandeur. Four villages partly occupy the ancient site, Luxor and Karnak on the eastern, and Gourneh and Medinet Abu on the western bank of the Nile. The eastern half contained the great body of the population, the two obelisks of Rameses III., one of which now stands in the Place de la Concorde at Paris, and the Palace of the Kings, with its great hall 329 feet long by 179 feet broad. In the western portion, besides the two famous statues of Memnon (q. v.), were the Menephthium, Memnonium, Thothmesium, and other temples and palaces, rising in terraces one above the other, and connected by avenues of colossal sphinxes, which led to the Necropolis, extending for 5 miles along the Libyan Hills. See Captain Abney's *T. and its Five Greater Temples* (Lond. 1877), Miss Edwards' *One Thousand Miles up the Nile* (Lond. 1876), and Baedeker's *Egypt* (new ed. 1878).

Thecodon'tia, an order of extinct *Reptilia*, regarded by Owen as crocodilian in character, but by Huxley and others as resembling the *Deinosauria* (q. v.) more closely than Crocodilia. Owen defines Thecodont reptiles as having biconcave vertebræ, with the ribs of the trunk long and bent, the front ribs having a divided head. The sacrum consists of three vertebræ, and the femur or thigh has a third trochanter. The limbs are adapted for walking. The teeth have compressed crowns, are pointed with serrated margins, and arise from distinct *alveoli* or sockets. The T. belong to the Triassic age. *Belodon*, *Palæosaurus*, and *Thecodontosaurus* are three notable genera.

Theft. See LARCENY OR THEFT.

Theiss (Mag. *Tisza*), the largest river of Hungary and the principal tributary of the Danube, is formed by the Black T. from Czorna and the White T. from Rusky in the Carpathian mountains. It flows first N.W., then S.W. and S., past Szigeth, Tokay, Szolnok, Csongrad, Szentes, and Szegedin, until it joins the Danube 5 miles below the town of Titel, after receiving from the right the Borsova, Bodrog, and Hernad, and from the left the Visso, Szamos, Korös, and Maros. The T. is 840 miles in length, and its basin has an area of 80,000 sq. miles. It is navigable for large vessels at Szolnok, and has at Tokay a breadth of 200 feet, at Szegedin 400 feet, and at Titel 740 feet.

Thel'wall, John, born in London, 27th July 1764, after a brief apprenticeship to a tailor, studied law, but refusing from conscientious scruples to be called to the bar, entered on a literary career (1785). His *Poems on Several Occasions* (1787) were followed by *Poems written in the Tower and Newgate*, whither his bold harangues in favour of the French Revolution brought him in 1794. With Horne Tooke and Hardy he was tried for high treason but acquitted, after which he became a public lecturer on politics, and in 1801 on elocution, as such distinguishing himself by his treatment of stammering. He published several works upon this and kindred subjects, and died at Bath, 17th February 1834. See his Life, by his widow (1837).

Them'is (Gr. 'law established by old usage'), daughter of Uranus and Gaia, is in the Homeric poems the embodiment of law and order, convoking the council of the gods at the command of Zeus. The worship of T. was established at Olympia, Thebes, Athens, Tanagra, and Trœzene. On coins T. is figured like Athena, and has a cornucopia and pair of scales.

Themis'tocles, an eminent Athenian general, was born at Athens about 514 B.C. His youth was wild and stormy, yet from an early age he showed a strong inclination towards politics, in which his great talents soon began to exhibit themselves. He attached himself to the democratic party in the state, and during the enforced exile of his rival Aristides he ruled the state with almost absolute sway. His great object was to make Athens a naval power. To this end he persuaded the citizens to spend part of the revenues of the city on ships instead of dividing them. In 480 B.C. Xerxes invaded Greece, and the wisdom of the council of T. became apparent. At the battle of Salamis (480) the combined Greek fleet defeated the Persians and destroyed the majority of their vessels. It was recognised that this victory was largely due to T., and all Greece showered thanks and honours upon him. By his advice the Athenians restored their walls, which the Persians had pulled down. The ungenerous opposition which the Spartans made to this necessary work of self-defence was defeated by the skilful diplomacy of T., who at this time was at the summit of his power. A change soon came. He was accused of dishonourable conduct, the Spartans banded themselves with his enemies in the city against him, and in 471 the fickle populace ostracised the man who had saved Greece. T. went first to Argos, and remained there till in 466 the Athenians, instigated by the Spartans, sent to arrest him on a charge of treason. He then fled to Corcyra, and from thence to Epirus, but the vengeance of his foes still pursued him, and he was forced in 465 to take refuge at the court of Artaxerxes the successor of Xerxes. He was warmly welcomed, for the king believed he might yet conquer Greece by the help of the man who had saved her. T. encouraged these hopes, indeed they were his only passport to favour at the Persian court, but he died in 449 without having done anything to realise them. He was a man of brilliant and versatile genius, but destitute of fixed moral principles. To some extent he was patriotic, but his country always stood second to himself. Of that higher patriotism which moves the truly heroic soul to love and serve an ungrateful fatherland he was entirely destitute.

Thénard, Louis Jacques, a French chemist, was born at La Louptière (Aube), 4th May 1777; studied chemistry at Paris under Bauquelin, was appointed (1810) Professor at the College de France, and later at the Polytechnic School and in the philosophical faculty of the University; in 1825 was created Baron, and in 1852 peer of France. In 1837 T. resigned his professorship at the Polytechnic School, and in 1840 that at the University. In 1842, however, he became grand officer of the legion of honour, and in 1850 member of the Council of Public Instruction. He died at Paris, June 21, 1857. T.'s chief work is *Traite de Chimie Élémentaire* (5 vols. Paris 1813–17; 6th ed. 1833–36). Along with Gay-Lussac he published in 1816 *Recherches Physico-Chemiques*, and for several years was co-editor of the *Annales de Chimie* and *Annales de Physique et Chimie*.

Thenard's Blue is a mixture of the phosphates of cobalt and alumina, and is prepared by calcining in a covered crucible phosphate of cobalt with precipitated alumina.

The'obald, Lewis, the son of a Kentish attorney, was born at Sittingbourne, in the latter part of the 17th c. Educated for the law, he turned aside to literature, and in 1714 published a translation of the *Electra* of Sophocles, followed in 1715 by translations of the *Œdipus*, the *Plutus*, and *Clouds* of Aristophanes, and an original tragedy entitled *The Persian Princess*. To these were subsequently added contributions in opera, melodrama, and pantomime, besides the tragedies of *The Perfidious Brother* (1716) and *The Double Falsehood, or, the Distrest Lovers* (1727), the latter of which was brought out at Drury Lane as a play of Shakespeare's. None of these efforts, however, would have preserved T.'s name. He owes his unhappy immortality to a quarrel with Pope. In 1726 he put forth a pamphlet called *Shakespeare Restored, or, Specimens of Blunders Committed and Unamended in Pope's Edition of this Poet.* Pope revenged himself by making T. the hero of the *Dunciad*; but when T.'s own edition of Shakespeare was published (Lond. 7 vols. 1733) he in turn enjoyed a triumph. Thirteen thousand copies of it were sold, and the reputation of Pope's edition was ruined. T. died September 18, 1744.

Theobro'mine ($C_7H_8N_4O_2$), a feeble base present in cocoa and chocolate, is extracted from cacao-beans in much the same way in which caffeine is extracted from coffee. When pure it is a colourless, crystalline powder, sparingly soluble in boiling water, and still less so in alcohol and ether. It gives crystalline salts with certain acids. From theobromide of silver, Caffeine (q. v.) may be prepared along with iodide of silver by treatment with iodide of methyl, so that caffeine ($C_7H_7CH_3N_4O_2$) may be regarded as methyl T.—a hydrogen molecule being replaced by a methyl molecule.

Theoc'racy (Gr. 'government by God') is a form of government in which the national deity is also regarded as the king of the nation; in other words, a stage of civilisation and religion in which political power is exercised by a sacerdotal caste. The most notable instance of a T. is found among the Israelites previous to the election of Saul as king.

Theoc'ritus, the most celebrated of the Greek bucolic poets, was, according to an epigram in the Greek Anthology (Brunck, *Anal.* vol. i. p. 263; Jacob's *Anth. Græca*, vol. i. p. 194; vol. vi. p. 490), a native of Syracuse and son of Praxagoras and Philina. Suidas, however, adds that some made him the son of Simichus or Simachidas, and that he was a native of Cos and only a *metoikos* at Syracuse. This statement vanishes on investigation. The use of the term *Simichidas* in a verse of the *Syrinx* carries nothing with it. We might as well conclude that the real name of Virgil was *Tityrus*, from the pseudonym adopted by him in the first of his Eclogues. The whole of the averment regarding Cos seems to have arisen out of his connection with Philetas, whose pupil he was (*vid. Schol. ad Id.* vii. 40). T. seems to have been intimately associated with the poet Aratus, author of the *Phænomena.* This is not strange, since the court of the Ptolemies was the mart of intellect then; and we know for certain that T. at least once in his life visited that great centre of poetry and philosophy. More than one of his idylls may have been written there; there can be no doubt left in the mind of a careful reader that he was at Alexandria and enjoyed for a time the friendship and patronage of Ptolemy Philadelphus (*vid. Idyl.* xiv. xv. xvii.). His 16th Idyll was unquestionably written at Syracuse, after the accession of Hiero (270 B.C.). The inference from all that can be gleaned from the poet himself as to his period, is that he flourished 284–262 B.C. It is impossible to discuss here the question of T.'s intimacy with Philetas, or the influence of the works of that poet on his mind. It is at least certain that T. was at Syracuse during the reign of Hiero II., and it is extremely probable that his 16th Idyll was written after that monarch's alliance with the Romans, B.C. 263 (*vid. Id.* xvi. 76, 77). T. was far from being satisfied with his treatment at the court of Hiero, or with the state of affairs generally (*vid. Id.* xvi. *passim*). How he spent his later years is wholly unknown, yet we may well suppose that the closing period of his life was devoted to the contemplation and enjoyment of rural life, the praise of which has made his name so famous and won for him the foremost place among bucolic bards. The genuineness of some of the idylls is disputed. This could hardly be otherwise. But the chief glory of T. lies in his being the founder of a fresh and fertile school of poetry. Bion and Moschus, a little later, achieved distinction in the same walk. Virgil drawing from the same sweet well enriched Roman literature with poems of marvellous beauty, however inferior to those of his prototype. Legends that blossomed into birth in the popular myths sung aforetime by Stesichorus and Sophron, assumed under the master-hand of T. a freshness which never failed to charm. For his idylls are the very quintessence of natural delights—whispering pines, shepherd-loves, and mildly-moaning waves. His idylls might have been written yesterday. In character they are mimetic and dramatic. Yet they are in the strict sense of the term *Eidullia.* Innocence, simplicity, fidelity—the characteristics of the early Sicilian race—constitute his objective theme. The *Adoniazusæ*, a masterpiece of depiction of female character, is characterised throughout by genuine dramatic force and spirit. Language and rhythm, symmetry and proportion, with the rare faculty of easy transition, were with T. natural gifts. Above all, he had a thorough knowledge of his art and of its limits. Incongruities of style and subject may occasionally be detected in his idylls, but in the writings of what poet is it otherwise? It may be mentioned that the pieces, the genuineness of which is disputed, are the 12th, 17th, 18th, 19th, 20th, 26th, 27th, 29th, 30th. For full information on the integrity of the poems, the reader is referred to the works of Eichstädt, *De Carm. Theoc. ad sua genera revocat.*, &c. (4to. Leip. 1794); E. Rheinhold, *De genuinis Theocr. Carm. et suppositis* (Jena 1819); and A. Wissova, *T. Theocriteus* (Wratislaw 1828), with the prefaces of Warton, Meineke, and Wüstemann, in their editions of T. The *editio princeps* of the idylls without place or date is supposed to have been printed at Venice, 1481. The next is the Aldine (fol. Ven. 1495). More recent editions are those of Warton (2 vols. 4to. with notes 1770); Brunck (4to. 1772); Gaisford, in his *Poetæ Minores* (8vo. Oxon. 1816, 1820–23); Meineke (12mo. Leip. 1825); Wüstemann in Jacobs' and Rosts' *Bibliotheca Græca*—a most useful edition (8vo. Gothæ 1830); Wordsworth (8vo. Cantab. 1844); Paley (8vo. Cantab. 1863); and Snow (Oxf. Clar. Press 1869). The edition of H. L. Ahrens (Leip. 2 vols. 1655–59) is the most critical and in some respects the best of all; but the unceremonious way in which he has dealt with the text in poems of acknowledged genuineness is a fatal blot on a work of singular scholarship and ability. T. has been done into most of the tongues of Europe. Some of the German renderings are exceptionally good. English translations are numerous. Those of Creech, Hoyland, Fawkes, Polwhele, Chapman, and Calverly are the most notable.

Theod'icy (Gr. 'the judgment of God') is any theory professing to reconcile the attributes of God with the present order of things in the world; or, more specially, an explanation of the existence of evil. According to the Christian doctrine of Divine Providence, man is the great end of creation, and the whole economy of nature is made subservient to the education of mankind. But Christian writers from the first felt a difficulty in avoiding anthropomorphic language in expressing the idea that God takes care of individuals, and in reconciling the liberty of man with the love and justice of God. In opposition to Dualism (q. v.), the evils existing in the world were regarded either as the necessary consequences of sin, or as phenomena which, good in themselves, assumed the appearance of evil in consequence of our limited knowledge, the corrupt state of our mind, or the abuse of our moral freedom. The keynote of every T. was expressed by Chrysostom, 'Christians rise above all trials by love to God.' This theory was elevated into a philosophical science by Leibnitz in his work *Essais de Theodicée sur la Bonté de Dieu, la Liberté de l'Homme, et l'Origine du Mal* (1710).

Theod'olite (derivation uncertain), an important instrument for measuring angles in geodetic operations. As now constructed, the instrument consists of a telescope, mounted so as to be able to measure altitude and azimuth angles. There are two concentric horizontal circles, the one fixed and graduated, the other capable of rotation round a vertical axis, and working upon the fixed circle with an attached vernier for reading the angle of rotation indicated on the latter. On this upper movable circle a vertical circle is fixed, to the centre of which the telescope is pivoted. The instrument is set upon a tripod stand, and is adjusted by screws and levels.

Theodo'rus belonged to a wealthy family of Antioch, where he was born in the first half of the 4th c. In 393 he was made Bishop of Mopsuestia in Cilicia, and is thought to have died in the year 429. He was the most eminent exegetical writer of the Syrian school of his time. Like his contemporaries, Jerome (q. v.) and Chrysostom (q. v.), he held a liberal view of the inspiration of the Scriptures, and applied the grammatico-logical method to its interpretation, as opposed to the allegorical method of Origen (q. v.). In theology he contended against the current of popular opinion of the time on several points. 1. He denied that the Spirit owed his existence to the Son (see FILIOQUE). 2. He was the Father of the Nestorians (q. v.), in making a clear distinction between the divine and the human nature in the person of Christ, holding that the latter was developed into the former by a gradual process. His writings, most of which are lost, were anathematised after his death in an edict of Justinian (544), called 'of the three chapters' (*i.e.* articles). See Fritzche, *De Theodori Mopsuestiani Vita et Scriptis* (Halle 1837).

Theodore'tus, born at Antioch towards the end of the 4th c., and ordained Bishop of Cyrus, a small town near the Euphrates, 420, was a disciple of Theodore of Mopsuestia (q. v.), with whose opinions generally he agreed, and with whom he joined in defending those opinions in opposition to Cyril of Alexandria and the Fathers of the Council of Ephesus. Dioscorus, Patriarch of Alexandria, procured the condemnation of T. for Nestorianism in the second Council of Ephesus (449). But this sentence was reversed at the Council of Chalcedon (451), at which Dioscorus was condemned along with Eutychianism (q. v.); and T., who had been banished, was restored to his see, in which he remained in peace till his death about 457. T. wrote a number of valuable commentaries on the Scriptures, a Church History, which is a continuation of Eusebius, a history of heresies, various controversial writings, &c. The best edition of what are extant is by Schulze and Nösselt (Halle, 10 vols., 1768–74).

Theod'oric (Goth. *Thiudareiks*, 'king of the people;' Ger. *Theuderich*, later *Dietrich*) **the Great**, King of the East Goths, was the son of the Amal Theodemir by his favourite Erleva, and was born near Vienna, 455 A.D. The Byzantine Emperors Marcian and Leo I., having failed to pay the annual 300 pounds of

gold guaranteed to the E. Goths, the latter, pressed forward by hunger and the Huns, entered Illyria, and after a new treaty (462) sent T. as a hostage to the court of Constantinople. At eighteen he was restored to his father, whom he soon after joined in a new incursion into the Byzantine territory, and after whose death in 475 he extorted from the imperial government a grant of fertile lands in Upper Mœsia. Zeno, seeking his friendship, gave him the title of 'Patrician,' but continued to intrigue secretly against him, till T. suddenly took up arms, and seized the district of Pataulia in Illyria. The emperor soon made peace with a new treaty that gave to T. part of Dacia and lower Mœsia, with the title of general and consul, in return for which he quelled the rebellion of Johannes in Asia Minor. The Rugians, hard pressed by Odoacer, now called on T. for help. The Byzantine court was glad to avail itself of the opportunity of turning the ambition of its formidable neighbour in the direction of Italy. T. proceeded thither in 488, defeated Odoacer in three great battles, on the Isonzo (August 28, 489), at Verona (September 27, 489), and on the Adda (August 11, 490), and after a protracted siege took Ravenna, his last refuge. A treaty struck by the two leaders, dividing between themselves the government of Italy, was soon set aside through the murder of Odoacer by T. during a drinking-bout (March 5, 493). The Empire of the E. Goths now included Italy, Sicily, Dalmatia, Istria, and part of Pannonia, and T. was the most powerful of all the German rulers. His internal administration was wise and orderly. To his Goths he gave the third part of the lands and the defence of his empire, while to the Italians he confirmed the Roman constitution and law. Yet he could not bring about a true union of the two alien peoples, nor reconcile the Roman clergy to the Arian heresy of the Goths. He favoured art and learning, and adorned with fine buildings his residence cities, Ravenna and Verona. Though Thierry attributes to T. 'instincts the most violent, cruelty, cunning, and pitiless egotism,' it cannot be denied that for three-and-thirty years his reign was marked by wisdom, justice, and prosperity without a parallel from the days of the Antonines to the time of Karl the Great. A dark blot on his later reign is the execution of the philosophers Boëthius and Symmachus, whom he had held in high honour, on suspicion of complicity in a conspiracy. T. died August 30, 526, leaving no son. His crown passed to his grandson Athalaric, a boy of seven years, the son of his daughter Amalasmintha. T. lives in song and legend as Dietrich (q. v.) of Bern (Verona). See Gibbon, *Decline and Fall of the Roman Empire*, chap. xxxix.; Kingsley, *The Roman and the Teuton* (1864); Deltuf, *Théodoric, Roi des Ostrogoths* (Par. 1869).

Theodo'sius the Great, Roman Emperor, was born at Cauca in Galicia, Spain, about 346. At an early age he became a soldier, and continued in successful military service till the execution in 376 of his father, a distinguished Roman general, on some unknown charge. He then retired to Spain, but in two years was appointed by Gratian administrative head of the empire in the East. The empire was at that time threatened by the Goths, but T., by two decisive victories over the invaders, succeeded in repelling the danger. A new peril soon threatened the state. In 383 Maximus, a native of Spain then resident in Britain, raised a revolt against Gratian. In the war that followed he was successful; Gratian was slain and Maximus became emperor of a considerable part of the West. A hollow peace was made between T. and the successful rebel, but when the latter in 387 made an attack on Italy, then under the rule of Valentinian, brother of Gratian, T. at once declared war against him. In the ensuing contest he was completely successful; Maximus was killed, Valentinian reinstated, and the conqueror entered Rome in triumph. T. was now at the height of his greatness, but he had yet to learn that there was a power on earth—though it claimed to be not of the earth—that was greater than his. The imperial officer at Thessalonica, with some soldiers, had been murdered in a mob riot. T. inveigled the defenceless populace into the circus, and then let loose upon them a horde of barbarians. At least 7000 persons are said to have perished. St. Ambrose, Archbishop of Milan, received information of the massacre, and shortly after, as the emperor was about to enter the cathedral, the courageous prelate confronted him, taxed him with his crime, and refused him admittance. T. acknowledged his sin, but it was not till eight months had elapsed, and many humiliating penances had been performed, that the Church again restored him to full communion. In 391 T. returned to Constantinople, but next year he was again obliged to begin war against Arbogastes and Eugenius, who had dethroned and killed Valentinian, and seized the empire of the West. T. was once more successful. The usurpers were defeated and slain, but the conqueror did not live to enjoy the fruits of his victory. He died at Milan, 17th January 395, immediately on the conclusion of the war. T. was zealously orthodox, and prosecuted heathens and heretics with equal ardour. By severe enactments he finally destroyed Paganism, and it is largely due to him that the 'Arian Heresy' did not become the creed of Christendom. He was an able general and a sincere man, though violent bursts of passion marred his character. See Fléchier, *Histoire de Theodose*; Gibbon, *Decline and Fall of the Roman Empire*; Müller, *De Ævo Theodosiano* (1797–98), and Dr. A. Güldenpenning and Dr. J. Ifland, *Der Kaiser T. der Grosse* (Halle 1878).—**T. II.**, Emperor of the East (408–450), was the son of the Emperor Arcadius, whom he succeeded, and grandson of T. the Great. During his reign he was engaged in war with the Persians and Huns. His reign was inglorious, his character unkingly. Yet in a private station, the pious, temperate, and lettered T. might have found a better field for the exercise of his virtues. He died in 450, and was succeeded by his sister Pulcheria, who had long really ruled the state. During his reign the *Codex Theodosianus* was published (see CODE). See Gerlach, *De Theodosio Juniore* (Zittau 1751), and Gibbon's *Decline and Fall of the Roman Empire*.

Theodo'tion, a native of Sinope or Ephesus, is the author of a Greek version of the Old Testament. He flourished in the latter half of the 2d c.; was first a disciple of Tatian, then a Marcionite, and finally an Ebionite. His version is simply a [illegible] of the Septuagint disfigured and accommodated to his Ebionitish opinions. Singular to say, in spite of its heretical origin, it was not rejected by the Church, and was even in some parts, *e.g.* the Book of Daniel, a special favourite.

Theog'ony (Gr. 'the genealogy of the gods') is the [illegible]al name given to that part of classic mythology which treats of the descent of the gods. Hesiod (q. v.) is the author of a poem on the subject.

Theol'ogy (Gr.) means literally a discourse about the gods, and Orpheus, Hesiod, and Homer were called 'theologians' among the Greeks because their poems treated so much of the gods. Aristotle classed the sciences under the heads of Physics, Mathematics, and T.; and the Christian Fathers called St. John The Theologian, because the divinity of Christ is rendered so prominent by him. Other definitions of T. are 'the science of the supernatural,' 'of divine things' (Hooker), and 'of religion;' but in all those there is involved a certain ambiguity, owing to the difficulty of agreeing on what these terms precisely denote. T. is accordingly defined as 'the science which is concerned with the facts of divine revelation contained in the Bible, so far as they concern the nature of God and our relation to Him as His creatures, as sinners, and as the subjects of redemption.' But as some of those facts are revealed in the works of God, a distinction is made between Natural T. and Christian T. proper. See Hodge, *Syst. Theol.* (Edin. 1873).

Theophras'tus, a Greek philosopher of the peripatetic school, was born at Eresus, in Lesbos, about 371 B.C. He studied at Athens under Plato and Aristotle. On the death of the latter, T. succeeded him as head of the Academy, and spent a long and honourable career in explaining and expounding his predecessor's doctrines. The date of his death is quite uncertain. It seems not to have been earlier than 285 B.C. T., like his master, wrote works on a variety of subjects. Many of them are lost, but we still possess—1, *The Characters*, a sketch of the most common human vices; 2, part of a work on Metaphysics; 3, a treatise on Sensation; 4, a History of Plants in ten books; 5, a work on the Causes of Plants, in ten books, some of which are yet extant; 6, a work on Stones; 7, a treatise on Fire, in two books, one of which remains. We have besides a host of fragments on kindred topics. The best edition of T. is by J. G. Schneider (5 vols. Leip. 1818–21). See Kirchner, *Die botanischen Schriften des T.* (Leip. 1874).

The'ory (Gr. *theōreō*, 'I look at,' or 'I contemplate') is a philosophical and scientific term of somewhat loose application. Generally it is used in opposition to 'practice,' as science is opposed to art. It is thus a general body of truth on any subject.

Sometimes it means the same as hypothesis, and in this sense may denote something false, as when we say, 'this T. of the relations of capital and labour is quite erroneous.' At other times it is used to mean a definite principle scientifically ascertained to be true, as the T. of gravitation.

Theos'ophy (Gr. 'divine wisdom') is a general name given to those systems of philosophy which profess to attain to a knowledge of the Divine Being by spiritual ecstasy, direct intuition, or special individual relations. Neoplatonism (q. v.) is a typical example of such a system. See MYSTICISM.

Therapeu'tæ (Gr. 'physicians') were a sect of ascetics mentioned in a writing ascribed to Philo (q. v.)—*De Vita Contemplativa*—who, seized with a longing for a divine life, forsook home and goods, relations and friends, and settled in the solitude of the country. The greater number lived near Lake Mareotis, to the S. of Alexandria, each in his own cell, in which he lived alone for the whole week, not even looking out. They prayed at the dawn and at twilight, and in the intervals studied their sacred books. None ate till night, while many fasted altogether for several days, and some for the whole week. Sabbath was the day for meeting in their common sanctuary. From the description given by Philo, the T. were always supposed to be a branch of the Jewish sect of the Essenes (q. v.), between whom and the T. there was the closest resemblance. Eusebius expressed the opinion that the sect described by Philo was the Christians. Several eminent scholars are now of opinion that the book *De Vita Cont.*, in which is the only mention of the T., was composed in the name of Philo by a later writer (3d c. ?), who sought to give his ideal of asceticism.

Therapeut'ics (Gr. *therapeuō*, 'I heal') may be defined as the science of the application of medicines to the cure of disease. T. treats of the various actions of medicines upon the diseased system, and the means by which nature may be aided in her return to health.

There'sa, St. See TERESA.

Therapi'a, a village on the Bosphorus, 21 miles E.S.E. of Constantinople, from which it attracts many residents by its beautiful situation and delightful climate.

Theresio'pel, or **Maria Theresiopel** (Hungar. *Szabadka*), a straggling agricultural town in the Bácska, the most fertile corn district of Hungary, between the Theiss and the Danube, 30 miles S.W. of Szegedin by rail. It has a large trade in corn, hides, wool, wine, fruit, and tobacco. Pop. (1869) 56,323.

Theri'aca (from Gr. *thēr*, 'a wild beast') originally denoted a compound prepared by Andromachus of Crete, physician to the Emperor Nero, which continued in high repute until recent times. In Venice, Holland, France, and other places it had to be prepared with certain solemnities in the presence of the magistrates. It received its name from the belief that it was an antidote to the poison of venomous creatures. The word *treacle* is a corruption of T., and was first applied to a syrup, medicine, or electuary, and then, from similarity of appearance, to the uncrystallised residue obtained in the preparation of sugar, and known as molasses.

Ther'midor', called also **Fervidor**, the 11th month in the calendar of the First French Republic, lasting from July 19th to August 17th. Memorable in the history of France is the 9th T. of the second year (July 27, 1794), the date of the fall of Robespierre and the termination of the Reign of Terror. Those who had brought it about were afterwards known as *Thermidoriens*.

Ther'modynam'ics, as the name implies, is the branch of theoretical physics which treats of heat as a mechanical agent, and is the basis upon which the modern doctrine of energy is built. The second interpretation given by Newton of his third law of motion (see MOTION, LAWS OF) all but enumerates the principle of the conservation of energy. Ignorant, however, of the true nature of heat, he was unable to trace the mechanical loss caused by friction to its final issue. Not till more than a century after the publication of the *Principia* was any attempt made to fill the gap, and then the valuable experimental results of Rumford (1798) and Davy (1799), though conclusively disproving the accepted caloric theory, were given to an unappreciative world, and failed to excite any real interest until forty years later, when their discoveries were rediscovered. In 1812 Davy wrote, 'The immediate cause of the phenomenon of heat then is motion, and the laws of its communication are precisely the same as the laws of the communication of motion.' Here then the dynamical theory of heat was enunciated, but it was carried no further, and not till the experiments of Colding and Joule, executed independently about 1840, were published, can T. be regarded as established. About the same time Séguin and Mayer approached the same subject, and deduced from experiment values of the mechanical equivalent of heat (see EQUIVALENT, JOULE'S). They, however, went to work upon hypotheses or rather different forms of the same hypothesis which we now know to be false; so that their claims as the *founders* of the doctrine of energy cannot be maintained against those of Colding and Joule, who went to work in a legitimate way. Mayer, however, deserves great merit for the manner in which he has developed and applied the conservation principle. In the more restricted sphere of T., Clausius, Rankine, and Thomson have been the great developers; and to the last-mentioned is due the modification of Carnot's forgotten cycle of operations to suit the true theory, and the deduction therefrom of the doctrine of the dissipation of energy. T. is based upon two laws. The first law enunciates heat to be a form of energy and subject to the conservation principle—an experimental truth rigorously established by Joule. Clerk Maxwell gives it in the form: When heat is transformed into work or work into heat, the quantity of work is mechanically equivalent to the quantity of heat. A given quantity of work can always be transformed into an equivalent quantity of heat; but in transforming heat into work a certain limitation exists which is expressed in the second law of T. This law asserts that it is impossible, by physical processes, to transform any part of the heat of a body into mechanical work except by allowing heat to pass from that body to another at a lower temperature; or in Thomson's words, it is impossible by means of inanimate material agency to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of the surrounding objects. This is the law upon which Carnot's principle is based—a principle which has led to results of the highest consequence. The principle is that the efficiency of a *reversible engine* is the greatest that can be obtained with a given range of temperature. Now a reversible engine, in Carnot's sense, is an altogether unrealisable heat engine, which can be made to go through a complete cycle of operations, either forwards or backwards. In other words, not merely is the engine able to do work while it transfers a given quantity of heat from the boiler to the condenser, but, by an expenditure of an equivalent quantity of work upon it, may be made to take back the same quantity of heat from the condenser to the boiler. In subjecting such an engine to a cycle of operations, the engine must be brought back to its original condition before any conclusion can be drawn regarding the relation between the heat which has disappeared and the work which has been done. Séguin, when he assumed that the work done by an expanding heated body was the equivalent of the heat which it loses, and Mayer, when he went to work upon the hypothesis that the amount of heat produced in compressing a gas is equivalent to the work done in compression, violated this principle, so that their conclusions were logically untrustworthy. It is easily demonstrable, upon the conservation principle, that Carnot's reversible engine is the most perfect possible engine, and that consequently all reversible engines working between the same temperatures have the same efficiency. For a small difference of temperature the efficiency is a function only of the temperature, and this efficiency, divided by the difference of temperatures, is called Carnot's Function. Thomson, defining temperature as the reciprocal of Carnot's function, has constructed a scale of temperature absolutely independent of the nature of the thermometric substance. Hence if t is the temperature measured according to this absolute scale of the source of heat, and t' that of the refrigerator or condenser, the efficiency may be expressed by the fraction $\frac{t-t'}{t}$. Now the efficiency is defined as the ratio of the work done to the heat supplied expressed in dynamical measure. Hence, if W is the work done, H the heat supplied to the engine, and h the heat given out to the condenser, all expressed in dynamical measure, we have

$$\frac{W}{H} = \frac{t-t'}{t}$$

$$W = H - h$$

whence $$\frac{h}{H} = \frac{t'}{t}$$

or, in a reversible engine the heat rejected is to the heat received as the absolute temperature of the refrigerator is to the absolute temperature of the boiler. From the first of these equations it is evident that the heat supplied cannot be wholly transformed into work unless the refrigerator is at absolute zero of temperature, a practical impossibility. Consequently, in a material system only a part of the intrinsic energy is available for work, and this available portion or *entropy* is continually diminishing because of the universal tendency of heat to diffuse itself, and reduce the system to a uniform temperature, when of course no work can be produced. This is Thomson's principle of the dissipation of Energy (q. v.). See Tait's *T.* (2d ed. 1877); Clerk Maxwell's *Theory of Heat* (1871); Tait's *Recent Advances* (1876); Rankine's *Steam-Engine* (1859), and the original papers of Clausius, Thomson, and Rankine, published in *Poggendorff's Annalen, Philosophical Transactions, Philosophical Magazine,* &c., within the last thirty years.

Ther'mo-Electri'city. At the surface of separation of any two different substances a difference of electrical potential exists, which is evidenced by the electrification consequent upon their being mechanically pulled asunder. If a circuit of two or more simple conductors (metals, for example) be formed, a difference of potential will exist at each junction; but as long as the junctions are kept at the same temperature the contact forces will balance, and no current will flow. If, however, one junction be heated, the potential equilibrium is destroyed, and, as first observed by Seebeck, a *thermo-electric* current will in general flow. Take for instance a simple circuit of iron and copper wire, and let a delicate galvanometer be included in the circuit, then if the one junction is gradually raised in temperature a current will be observed to set in, flowing from the copper to the iron through the hot junction. The effect is qualitatively the same if platinum be substituted for iron; but if palladium be used instead, the current is reversed, and flows from palladium to copper through the hot junction. In this way a thermo-electric series may be arranged, such that in a circuit formed with any one metal and one further down the list, the current produced by a *small* difference of temperature of the functions will flow from the latter to the former through the hot junction. Such a list is the following: iron, platinum, cadmium, silver, zinc, copper, lead, potassium, sodium, palladium, nickel, cobalt. The expression small difference is used advisedly, for experiment has proved that for larger differences of temperature the direction of the current may become reversed. Thus Cumming, in 1823, discovered that when one junction of an iron-copper circuit was kept at an ordinary temperature, and the other raised gradually, the current continued to increase until the temperature of the hot junction reached about 280° C., when the current reached its maximum, and on further heating began to fall off, until at about 560° C. it became reversed. This critical temperature is called the *neutral point*, and is different for every different pair of metals, being for some below zero, for others at a moderate temperature, and for others at a temperature too great for one or both metals composing the circuit. In every case, however, a neutral point is indicated by the relation between the electromotive force and the temperature. For all the ordinary metals, Tait has proved that the electromotive force satisfies the equation

$$E = a(t_1 - t_2)[t_0 - \tfrac{1}{2}(t_1 + t_2)].$$

Where t_1, t_2 are the temperatures of the junctions, t_0 the neutral point, and a a constant whose value and sign depend upon the particular metals employed. In other words, the electromotive force is a parabolic function of the temperature. These currents are evidently closely connected with the phenomenon discovered by Peltier, that when a current crosses the junction of two metals, the junction is heated when the current is in one direction, and cooled when it is in the other. Thus if a current be passed round an iron-copper circuit, the junction at which the current passes from iron to copper is heated and the other cooled, so that a reverse thermo-electric current is at once called into existence. Conversely when a thermo-electric current is maintained in a circuit, there is in consequence of the Peltier effect absorption of heat at the hot junction with simultaneous evolution of heat at the cold. Applying the laws of thermodynamics to the problem, Sir W. Thomson was led to the discovery of a most important and quite unexpected phenomenon, which he has called the electric convection of heat. He at once tested his theoretical result by experiment, establishing that a current flowing in an unequally heated iron bar carries heat from the cold parts to the hot parts, while in copper the current has an equalising effect upon the distribution of temperature throughout. Nickel, cobalt, palladium, and perhaps platinum, are similar to iron, while most of the other metals resemble copper. According to Le Roux, the effect in lead is inappreciable, and Tait has shown that at a high temperature the effect in iron and nickel is reversed, but at still higher temperatures becomes as it was before. The constant a in his thermo-electric formula depends upon the relative values of the effects in the metals used. The phenomenon is evidently the inverse of the discovery made by Magnus, that if the ends of the same wire are at different temperatures and they are brought into contact, an instantaneous current passes, the direction of which depends upon the metal. T.-E. has been practically applied for thermometric purposes in the thermo-electric pile, which consists of alternating strips of antimony and bismuth. The multiple junction so formed is very sensitive to minute differences of temperature, which are indicated on a galvanometer introduced into the circuit. See Thomson 'On the Electrodynamic Properties of Metals' (*Phil. Trans.* 1856), Tait's 'First Approximation to a Thermo-electric Diagram' (*Trans. of the Roy. Soc. of Edinburgh,* 1870-71), and Clerk Maxwell's *Electricity and Magnetism.*

Thermom'eter (Gr. *thermos*, 'heat,' and *metron*, 'measure') is an instrument for measuring the Temperature (q. v.) of a given body. The principle of its action depends upon a nearly universal property which matter has of expanding when heated. If the substance during the operation does not change its physical condition, as from solid to liquid or liquid to gaseous, this expansion is accompanied by a rise of temperature, to which for all bodies within certain limits the amount of expansion is approximately proportional. All gases, if they are not near their point of liquefaction, expand under the influence of heat very nearly according to Charles' Law, which states that at constant pressure the increase of volume is directly proportional to the rise of temperature, and is the same for every gas. Theoretically, then, we have here a method by which temperatures over a wide range can be measured; but practically the construction of a gas or air T. is extremely difficult, so that for ordinary thermometric purposes recourse must be had to the more convenient though less accurate liquid T. The expansion of solids is too small to be of any practical use. The liquid most generally employed is mercury, which, in virtue of many of its physical properties, is peculiarly suitable for these purposes. Its specific heat is small, so that a very small percentage of the heat which is necessary to bring it into the same thermal condition as the body with which it is in contact is lost; its coefficient of expansion is large, and is very constant through a considerable range; its conductivity is great, and this, aided by the connection currents which exist in all unequally heated liquids, rapidly brings the liquid to the same temperature throughout; and its freezing and boiling points are far removed from the ordinary temperatures. An ordinary mercurial T. consists of a glass tube, the bore of which widens out into a bulb at the lower end. The upper end is hermetically sealed after the mercury has been boiled in it, so as to drive out all the air. On cooling to the ordinary temperature, the mercury contracts nearly all into the bulb, the volume of which should be great compared to the volume of the narrow bore. The tube is then graduated according to a convenient method, and the temperature is indicated by the height at which the mercury column stands in the tube. In the three received methods of graduation, the freezing and boiling points of water at a certain pressure are chosen as standard temperatures. They are determined for every T. by direct experiment; the corresponding heights of the mercury column are marked, and the interval is divided into a certain number of equal divisions called degrees, which are then continued below and above the standard temperature. The corresponding temperatures on the Fahrenheit, Réaumur, and Centigrade thermometers are as follows:—

	Fahr.	R.	C.
Freezing point of water	32°	0°	0°
Boiling point of water	212°	80°	100°

The Fahrenheit zero is below the freezing point of water, the Réaumur and Centigrade zeros represent that temperature. The number of degrees between the standard temperatures is 180 on

the Fahrenheit and 80 on the Réaumur T., numbers which were chosen on account of their breaking up easily into integral aliquot parts. The former is much used in England, the latter on the continent, especially in Germany; but for scientific purposes the Centigrade is the best, and will probably supersede the others in time. Mercury freezes at — 40° C. and boils at 350° C. Beyond these limits, then, the mercurial T. is of no use. For very low temperatures the spirit-of-wine T. is used, but for high temperatures the air T. must be employed, or a thermo-electric junction, or an ordinary Pyrometer (q. v.). The ordinary T. gives only the temperature at the time the observation is made; but for meteorological purposes it is necessary to know the minimum and maximum temperatures during a given period of time. There are various forms of such self-registering thermometers which fulfil these purposes. One very ordinary form of maximum T. has a constriction in the bore just above the bulb, which is set so as to droop when the T. is laid horizontally. The mercury in expanding is pushed along the tube to the maximum temperature, but on contraction when the temperature falls the cohesion of the mercury is not sufficient to pull it through the narrow constriction, and the upper part of the column lies in position until the temperature is noted. The observer then erects the T., and things assume their normal condition in readiness for a new experiment. In another form a small piston is pushed on by the column of mercury advancing along the horizontal bore, and is left when the mercury retires. A similar action takes place in the spirit-of-wine minimum T., the small movable piston being, however, immersed in the liquid, and dragged back by the convex surface of the contracting liquid. These are the ordinary forms of maximum and minimum thermometers; but there are numerous modifications introduced by Caselli, Negretti, and Zambra, and other scientific instrument-makers.

Thermop'ylæ (Gr. lit. 'hot gates,' *i.e.*, 'the gates of the hot springs'), a famous pass leading from Thessaly into Locris, between Mount Oeta and an inaccessible morass forming the edge of the Maliac Gulf. As the vale of Tempe in the N. of Thessaly was the only pass into northern Greece, T. in the S. of Thessaly was the only road by which an invading army could enter southern Greece; but, like the former, it could be avoided by a circuitous mountain track, which surmounted Mount Callidromus at the back of the pass, and was called Anapæa. T. was the scene of the memorable struggle of Leonidas and his 300 Spartans against the invading hosts of Xerxes (480 B.C.), and of the unsuccessful attempts of the Greeks to repel the Gauls under Brennus (279 B.C.). Here also the Ætolians vainly attempted to make a stand against Philip the Macedonian (207 B.C.), and Antiochus against the Romans under the Consul Acilius (187 B.C.).

The'seus, the great legendary hero of the Ionians, and especially of the Athenians, was the son of Ægeus, king of Athens, by Æthra, and was brought up at Troezene by his grandfather Pittheus. As soon as he became a man, he took the sword his father had hid for him under a block of stone, and proceeded to Athens, destroying on the way the robbers Periphetes, Skiron, Kerkyon, and Procrustes (q. v.). At Athens his stepmother Medea attempted to poison him; but Ægeus recognising him by the sword, Medea was forced to flee. T. rid the land of the Marathonian bull; and soon afterwards, the messengers of Minos (q. v.) coming to Athens to fetch the yearly tribute of seven lads and seven maidens for the Minotaur (q. v.), T. offered himself to make up the number, and succeeded in slaying the monster with the help of Ariadne (q. v.). After the death of Ægeus, T. was king of Attica, and distinguished himself by wise government and heroic deeds. He founded the Panathenaic and Isthmian games, joined Hercules against the Amazons, and carried off their queen Hippolyte, who bore to him Hippolytus. After helping Pirithous to expel the Centaurs, he descended with him to Hades, to carry off Persephone; but both were overpowered and held below in chains till freed by Hercules. T. also took part in the Argonautic Expedition and the Calydonian Hunt. On his return to Athens, finding Menestheus, son of Peteos, on his throne, he retired to Skyros, where he met his death either by a fall from a cliff or by the treachery of King Lycomedes. The story of T. is essentially the story not only of the Hellenic heroes Perseus, Bellerophon, Meleagros, Œdipus, and Hercules, but of Rustem, Feridoun, and Siegfried.

The'sis (from Gr. *tithēmi*, 'I lay down') is a brief statement of an opinion, view, or proposition, which he who states it is prepared to prove by detailed argument. In a special academic sense T. means the dissertation which candidates for certain university degrees are obliged to give in, and which in former times they were required to defend publicly against all comers.

Thesmopho'ria, an ancient festival held exclusively by women in several districts of Hellas, especially Athens and Arcadia, in honour of Demeter *Thesmophoros* ('the lawgiver') as the foundress of agriculture, and thereby of ordered civil life, with the institution of marriage. At Athens the festival extended to three days, beginning with the 24th October. On the first day there was a procession to the temple of Demeter at Halimos, S.E. of the city; on the second a strict fast; and on the third day, called *Kalligeneia* ('the bearer of a fair offspring'), a joyous and unrestrained carousal. The licentiousness of the T. is caricatured in the *Thesmophoriazousai* of Aristophanes. See A. Mommsen, *Heortologie* (Leip. 1864).

Thes'pis. See Drama.

Thessalo'nians, Epistles to the, written by the Apostle Paul to the believers in Thessalonica, the metropolis of the second part of Macedonia, are the earliest of St. Paul's writings, and perhaps the earliest written records of Christianity. Paul had visited the city on his second missionary journey, in company with Silas, and perhaps Timothy, soon after he entered Europe (Acts xvii.). Having been driven from the city by the opposition and persecution of the Jews, from Athens Paul sent Timothy to Thessalonica to bring him word how it fared with the newly-founded church. On being joined at Corinth by his messenger he wrote an epistle commending their faith and zeal, of which Timothy had brought him word, and warning them against the mistaken expectation of the immediate return of Christ, which was leading them to neglect their worldly callings. The Second was written soon after the First (1 T. i. 1, 2 T. i. 1), and therefore both about 52–53, from Corinth. Some critics maintain that the internal evidence indicates that the second epistle was written first. If so, it was probably written from Berea, its chief object being to instruct the believers regarding the second coming of Christ, and refute a forged letter which had been sent to them in the Apostle's name (*cf.* 2 T. ii. 2), and which distorted expressions he had used.

Thess'aly, the largest political division of ancient Greece, now part of European Turkey, extends in its widest sense from the country N. of Thermopylæ as far as the Cambunian Mountains, and is bounded W. by Epirus, N. by Macedonia, E. by the Ægean, and S. by the Maliac and Pagasæan Gulfs and Mount Œta. The great central plain of T., watered by the Peneius, is enclosed by mountains, the chief of which are Olympus, Pelion, and Ossa in the N., Othrys in the S., and Pindus in the E. This plain, the most productive in all Greece, was famed in ancient times for its wheat, its flocks and herds, and its fine breed of horses. In the greater part of its course the Peneius is shallow and sluggish, except after the melting of the snow, when it occasionally floods the adjacent country. It flows through the famous vale of Tempe. Despite oppressive taxation, the want of railways and good roads, and the depredations of brigands, T. under the Porte is still a richly productive country. In 1874 it yielded 375,000 quarters of wheat, 90,000 of barley, 12,000 of rye, 90,000 of Indian corn, 12,500 of sesame seed, 2,800,000 lbs. of sheep's wool, 276,000 of cotton wool, 275,000 of silk cocoons, and 1,600,000 of tobacco (4,125,000 lbs. in 1873). Large quantities of butter, cheese, of various kinds of pulse, of green and dried fruits, wine, olive-oil, cattle, skins (sheep, goat, and lamb), charcoal and firewood, are also despatched to the markets of Greece, Egypt, Smyrna, Constantinople, and Salonica. The chief town is Larissa, and the principal port Volo (q. v.).

History.—T. is said originally to have been known as Pyrrha, Æmonia, and Æolis. The first two names, however, belong to mythology, while the last was derived from the Æolian Pelasgi, who were expelled from the land by the Thessalians. The latter people are said to have been immigrants from Thesprotia in Epirus. Homer, who does not use the name T., speaks of the sons of Thessalus, the son of Hercules (*Il.* ii. 676). It was early divided into four tetrarchies—

Thessaliotis, Pelasgiotis, Histiæotis, and Phthiotis — which were nominally united under a chief magistrate called Tagus, who seems only to have been appointed in time of war. But the cities, upon which the smaller towns were dependent, administered their own affairs. The three most important, Larissa, Pharsalus, and Pheræ, while torn by internal faction, were often at feud with one another. Hence T. never attained a position in Greek history corresponding to its population and wealth. Philip of Macedon conquered T., which remained under the Macedonian kings till the battle of Cynoscephalæ (B.C. 197) brought it under the sovereignty of Rome. In the constitution of the empire after the time of Constantine, T. appears as a separate province administered by a præses. Since 1460 it has belonged to the Porte. Under the treaty of Berlin (13th July 1878) the Porte is recommended to give Greece an extension of territory in T. and Epirus. For a long time the country has been in a disturbed state, and Greek troops have been massed on the frontier.

Thet'ford, a town on the S. border of Norfolk, England, on the Little Ouse, 31 miles S.W. of Norwich by rail. It has three churches, St. Peter's, St. Mary's, and St. Cuthbert's (restored 1875). Other buildings are the guildhall, mechanics' institute, and a grammar-school, which is now (1879) being rebuilt. Malting is the chief industry, but there are a paper-mill, a tannery, and several machine factories. There is also a large river traffic, chiefly in agricultural produce. Pop. (1871) 4166. A line to Bury St. Edmunds was opened in 1876, and in 1877 new waterworks were constructed, supplied by an artesian well 160 feet deep. T., the Roman *Sitomagus*, was capital of East Anglia, and in later times the seat of a bishop. See Hunt's *History of T.* (1870).

Thet'is, daughter of Nereus and Doris, and wife of Peleus, by whom she became the mother of Achilles. Her marriage was honoured by the presence of all the gods. Poseidon and Zeus are said to have sought her in marriage, but to have desisted when Themis declared that the son of T. would be greater than his father.

Thian'-Shan' ('celestial mountains'), a lofty chain in the heart of Central Asia, extends for 6000 miles from Karakali in the S.W. to Barakul in the N.E., increases in breadth from E. to W., sending off various spurs at right angles, among them Terek-Tagh, Alexander range, Transilenian, Atalan, &c. On the W. shore of Lake Issik-Kul the main range has a breadth of 900 miles. In the central part the peaks attain a height of 24,000 feet, and the passes, which are about 19,000 feet high, are partly covered with glaciers (*e.g.*, the Musart). Little is yet known of the geological structure of the T., but, according to recent accounts, the formation in the N.W. is Palæozoic. Granite and syenite are widely distributed, and together with white dolomitic limestone are found metamorphic schist and dark limestone. Active volcanoes are unknown, but there is an extinct crater near Urumsci, near the centre of the range. See Sewerzow, *Erforschung des T.-S. Gebirgessystems* (Gotha, 1875); Von Richthofen, *China* (Berl. 1877); Petermann's *Mittheilungen* (vol. vi. p. 236, 1878); and Prejevalski, *From Kulja across the Tian-Shan to Lob-nor* (Lond. 1879).

Thi'baudeau, Antoine Claire, Comte, was born at Poitiers, 23d March 1765, and became an advocate in 1789. He took some part in the Revolution, but was not a fanatical republican. Named by Bonaparte a member of the Council of State, he helped to draw up the Code Napoléon, was made Prefect of the department of Bouches-du-Rhone (23d April 1803), and a Count in 1809. In 1815, though he had disapproved the return of Napoleon, he yet opposed the recall of the Bourbons, and was banished. He travelled about Switzerland, Germany, &c., till 1830, when he returned to Paris, but lived in retirement till Louis Napoleon's *coup d'état*, after which he was named in the first list of members of senate, and was created a grand officer in the Legion of Honour, 11th August 1853. He died 8th March 1854. T.'s voluminous writings include his *Recueil des Actes héroiques et civiques des Républicains Français* (1795), *Mémoires sur le Consulat, par un ancien Conseiller d'État* (1826), *Histoire Générale de Napoléon Bonaparte* (6 vols. 1827–28), unfinished; *Le Consulat et l'Empire* (10 vols. 1835–38), *Histoire des États Generaux* (1843). His *Mémoires*, 1765–92, appeared at Paris in 1875.

Thick-Knee (also named 'Stone Curlew' and 'Norfolk Plover') is a *Grallatorial* or wading bird, the *Œdicnemus crepitans* of ornithologists. The T.-K. is allied to the Plover (q. v.). Its colour is brown, variegated with black, the head brown streaked with black, the chin and the under parts white. The average length is 17 inches. The bird is common in the flat lands of Norfolk from April to September. The eggs number two, and are of a light brown marked with slaty blue.

Thielt, a town of Belgium, province of W. Flanders, 20 miles W.S.W. of Ghent by rail, has some manufactures of linen, oil, &c. Pop. (1876) 10,209.

Thierr'y, Jacques Nicolas Augustin, born at Blois, 10th May 1795, from the college of his native town passed to the École Normale at Paris (1811). In 1813 he became a teacher at Compiègne, but within a twelvemonth returned to the capital, where as disciple and secretary he aided St. Simon (q. v.) in various socio-political brochures, and independently published *Des Nations et de leurs Rapports matériels* (1816). He next turned journalist, and in 1820 contributed to the *Courrier Français* ten *Lettres sur l'Histoire de la France* (1827; new ed. 1870). To history his attention had been turned by the reading of Scott's romances, and *Ivanhoe* suggested his *Histoire de la Conquête de l'Angleterre par les Normands* (1825; new ed. 1877; Eng. trans. 1825 and 1847). This, T.'s masterpiece, cost him his eyesight (1826), thenceforth he could only study with the aid of secretaries, friends, and the faithful wife, Julie de Querengal, whom he married in 1831 and lost in 1844. To the period of his blindness belong the *Dix Ans d'Études historiques* (1834; new ed. 1868), *Recits des Temps Mérovingiens* (1840; new ed. 1877), and *Essai sur l'Histoire de la Formation et des Progrès du Tiers État* (1853; new ed. 1868), all three translated into English. He was also one of the editors of the important *Récueil des Monuments inédits de l'Histoire du Tiers État*. Elected a member of the Academy in 1830, T. died at Paris, 22d May 1856.—His brother, **Amédée Simon Dominique** (born 2d August 1797, died 26th March 1873), was likewise a Liberal and an historian. Among his works were *Histoire de le Gaule sous la Domination Romaine* (1826), *Histoire des Gaulois jusqu'à la Domination Romaine* (1828), *Histoire d'Attila et ses Successeurs* (1856), and *St. Jérome* (1867).

Thiers, a town of France, department of Puy-de-Dome, on the Durolle, 25 miles E.N.E. of Clermont-Terrand by rail. It has a college, a technical school, chamber of commerce, &c., and is a great centre of the cutlery trade, which employs 12,000 men. There are also manufactures of paper, iron wares, asphalt, playing-cards, leather, &c. Pop. (1876) 11,182.

Thiers, Louis Adolphe, French statesman and historian, was born at Marseille 15th April 1797, his father being a poor workman, while his mother belonged to a bourgeois family almost equally poor, though remotely connected with the famous Chéniers. After studying as a bursar at the Lyceum of his native town, he went through a course of legal study at Aix and became an *avocat* in 1819. It is said that during his residence at Aix the Academy of that town offered a prize for an essay on Vauvenargues, upon which T. wrote two essays, taking up the subject from different points of view, gaining the prize for one of them, while the other obtained the second place. It was here that he formed a friendship with a brother historian Mignet, along with whom he began life in Paris in 1821, living in a miserable garret near the Palais-Royal. He soon obtained work as a political writer on the staff of the *Constitutionnel*, then the leading journal of the Opposition in Paris, and began to force his way in political circles, where the intimacy which he acquired with such men as Talleyrand, General Jomini, and the financier Louis, was of the greatest use to him in the preparation of his *Histoire de la Révolution Française*, begun in 1823 (in collaboration at first with Felix Bodin) and finished in 1827. This great work may be said to have marked the commencement of the Liberal reaction, in whose sequel T. took such a prominent part. It told the story of the great crisis clearly, calmly, graphically, and in the main accurately, and it neither attacked nor apologised for the principles of the Revolution, but simply took them for granted. Leaving the *Constitutionnel*, T., along with Armand, Carrel, and Mignet, founded a still more outspoken organ of liberalism in the *National*, whose first number appeared on

January 1, 1830. In it he waged war against the Polignac ministry, and in it appeared his famous definition of the duties of a constitutional monarch, *Le roi règne et ne gouverne pas.* The ordinances against the press which brought about the Revolution of July 1830, were answered by a protest drawn up by T. and signed by 43 Parisian journalists which was in fact the real signal for insurrection. After the Revolution T. attached himself to the Orleanist or Constitutional party, headed by Laffitte, and on the accession of Louis Phillipe he became a Councillor of State, was attached to the finance department, and entered the Chamber of Deputies, where, though his *début* was not very successful, his calm, incisive, and perspicuous oratory soon made him a power. He obtained the post of Minister of the Interior in Soult's cabinet of 1832, and afterwards held the office of Minister of Commerce and Public Works, then returned to the Ministry of the Interior, and in consequence of some difference with Soult resigned his portfolio on the 11th November 1834. A ministerial crisis followed, and in a week T. found himself reinstated in his office under the leadership of Mortier. From this time forward there was a breach between Guizot and T., who had hitherto worked apparently in accord. From February to August 1836, T. was at the head of the ministry, but differing from the king upon Spanish affairs he resigned his position, and did not again hold office until 1st March 1840, when he became President of Council and Minister of Foreign Affairs. He had been elected a member of the Academy in 1836. Immediately on his accession to power ensued the Eastern complications which led to the bombardment of Acre by the English, and the expulsion of Mehemet Ali from Syria. At this crisis T. placed himself in opposition to the policy of Lord Palmerston and the rest of Europe, menaced Germany with an extension of the French frontier to the Rhine, and at last, finding the king strenuously opposed to his warlike designs, gave in his resignation on the 29th of October 1840. He now retired into private life, occupying himself with his *Histoire du Consulat et de l'Empire*, published at intervals between 1845 and 1860. After the Revolution of 1848 he re-entered public life, exerting himself in the chamber against the Socialist tendencies of the crisis, and labouring openly for a restoration of the Orleans family. The *coup d'état* of 1851 led to his banishment, but he was soon permitted to re-enter France, where for the next ten years he occupied himself exclusively with literary and artistic pursuits. Re-entering the chamber in 1863, he became one of the leaders of the opposition, denounced from the commencement the war of 1870, and predicted its disasters. When his predictions were verified, he was once more brought prominently to the front in political life, and though he refused a place in the Government of National Defence, he rendered signal service in the committee for the defence of Paris. On the 12th of September he started on a diplomatic mission to London, Vienna, St. Petersburg, and Florence, from which he returned with nothing but empty promises of intercession on the part of the governments to whom he had applied for military aid, or at any rate authoritative intervention. Equally unfortunate were his negotiations with Prince Bismarck on the subject of an armistice, which lasted from the 30th October to the 6th November, and were at last broken off on account of Prince Bismarck's refusal to consent to the revictualling of Paris. After keeping himself in the background during the terrible winter of 1870–71, he was, on the summoning of the National Assembly, elected to it by no less than 26 departments, and became the head of the Provisional Government. In this position his energy and practical good-sense were of the greatest service in the peace negotiations with Germany, and in the perilous days of the Commune which followed close upon them. On the 31st of August 1871 his position at the head of the Government was ratified, and he was granted the title of President of the French Republic by a majority of 491 to 93. This post he held until the parliamentary crisis of May 24, 1873, when he was succeeded in the Presidency by Marshal Macmahon, and for the last time retired into private life. He died at his residence, St. Germain-en-Laye, 3d September 1877. T.'s mind was not of the very highest order, and he does not stand quite in the first rank either as a statesman or as an historian. He has been accused of a fatalistic worship of success, both in his philosophy as set forth in his writings, and in the practice of his life, but of this foible his consistent opposition to the Empire should in a great measure free his memory. Perhaps a keen practical sagacity, and a species of common-sense too seldom found among his compatriots, were his leading qualities, and it is certain that they enabled him to do his country most signal service in her direst straits. See A. Laya's *Études historiques sur la Vie privée, politique, et littéraire de M. A. T.* (Par. 1846), the same author's *Histoire Populaire de M. A. T.* (Par. 1872), the Biographies by Eggenschwyller (Bern 1878) and Frank (Par. 1877), Nassau W. Senior's *Conversations with M. T., M. Guizot, &c.* (Lond. 1878), and Jules Simon's *Gouvernement de M. T.* (2 vols. Par. 1878; Eng. Trans. 2 vols. Lond. 1879).

Thiersch, Friedrich Wilhelm, born at Kirchscheidungen, near Freiburg-an-der-Unstrut, June 17, 1784, studied theology and philology at Leipzig and Göttingen, and in 1809, following a call to the newly-founded Munich Lyceum, there founded a Philological Institute. The enthusiasm T. had shown in the German War of Liberation he presently directed to Hellenic regeneration, and in 1831 visited Greece, where on the murder of Capo d'Istria he co-operated towards the election of Otto of Bavaria to the throne. Returning to Munich, he was elected President of the Academy in 1848, and died February 25, 1860. Among his works were a *Griechische Grammatik* (1812), *Ueber Gelehrte Schulen* (3 vols. 1826–30), *De l'État Actuel de la Grèce* (1833), and *Ueber die neuesten Angriffe auf die Universitäten*. See *Friedrich T.'s Leben*, by his son (2 vols. Leip. 1866–67).

Thi'onville (Ger. *Diedenhofen*), a small fortified town of Germany, in Lothringen, on the Moselle, 18 miles N. of Metz by rail. It was taken by the Germans after a bombardment of two days, November 24, 1870. Pop. (1875) 7168.

Third, a musical interval. From C to E (four semitones) is a major T., from C to E♭ (three semitones) a minor T., from C to E♯ an augmented T., and from C to E♭♭, or from C♯ to E♭, a diminished T.

Thirl'age, in Scotch law, is a Servitude (q. v.) under which the proprietors are bound to have the grain produced on their lands ground at a particular mill, and to pay certain duties specified in the title. The principal duty is *multure*, which varies from about one-thirtieth to one-twelfth of the grain carried, or of the flour made. It is payable to the proprietor of the mill, or to his tenant. There are several minor duties. In England there is on some lands a custom to the same effect, but it is not general.

Thirl'wall, Conn'op, born at Stepney, 11th January 1797, at three learnt Latin, at four 'read Greek with ease and fluency,' and in 1809 figured as author of *Primitiæ*, a volume of sermons, tales, and verse. Charterhouse strengthened his precocious growth, and as scholar with Whewell, Sedgwick, and Julius Hare of Trinity College, Cambridge, he carried off the Craven, Bell, and senior chancellor's medal, and having graduated as a senior optime—there was then no classical tripos—was elected to a college fellowship (1819). His translation of Schleiermacher's *St. Luke*, introducing 'rationalism' to English theology, was made while he was a law student at the Temple, and he was actually called to the bar in 1825, the year when we find him one of a debating society whose members included Mill, Maurice, Macaulay, Sterling, the Bulwers, and Wilberforce. A Trinity tutorship, however, led to his taking orders and return to Cambridge, where with Hare he translated Niebuhr's *History of Rome* (1828), and became a joint-editor of the *Philological Museum* (1832–33), to it contributing among other essays on the widest subjects one, singularly subtle and profound, on *The Irony of Sophocles*. His *History of Greece* (1835–40; new and enlarged ed. 1856) was written under great disadvantages for 'Lardner's Cyclopædia,' and has been partly eclipsed by Grote's, but was the first (and last) Greek history that, rising above the school-book level, betrays no trace of party animus, whilst from its learning, accuracy, and dignified if passionless style, it must always rank as an English classic. His pamphlet on the *Admission of Dissenters to Academical Degrees* (1834) cost him his tutorship, but was rewarded by the Whig Government with the living of Kirkby-Underdale, and in 1840 Lord Melbourne raised him to the see of St. David's. In six months' time he could preach to Welshmen in the Cymric tongue, out of his revenues he expended in thirty years £30,000 on the augmentation of poor livings, and a long list might be formed of churches and schools built or enlarged through his munificence. But T.

is chiefly known to the outside world by his public utterances, the eleven Charges (1842-72), which, whether on Tractarianism or the Gorham controversy, Ritualism or *Essays and Reviews*, were always marked by a judicial fairness and that rarest quality of common-sense. The Liberal representative of the Bishops' bench, he stood alone or almost so in his attitude towards the removal of Jewish disabilities, the Maynooth Grant, Colenso's inhibition, and Irish Church disestablishment, while in Convocation he held the balance of opinion. Having resigned his see in 1874, he died at Bath, 27th July 1875, and was buried in Westminster Abbey side by side with Grote. The Rev. J. Perowne has edited his *Remains, Literary and Theological* (3 vols. Lond. 1877), which, comprising T.'s charges, sermons, speeches, and miscellaneous writings, will some day, says Professor Sayce, 'take a place in Anglican literature beside Hooker's *Polity*, the *Liberty of Prophesying* of Jeremy Taylor, or Butler's *Sermons*.' See the *Edinburgh Review* (April 1876) and *Theological Review* (April 1878).

Thirsk, a town of England, N. Riding of Yorkshire, in the vale of Mowbray, on the Cod Beck, a tributary of the Swale, 22½ miles N.W. of York by rail. It is divided by the Cod Beck into Old and New T., and a little to the S. is the suburb of Sowerby. The Mowbrays were a powerful baronial family here in the time of Richard I., and the church, a fine Perpendicular building, with a lofty tower and a splendid Irish oak roof, was gifted by Roger de Mowbray to Newbury Priory. A water company has been formed (1879) to convey 300,000 gallons daily from Boltby, 7 miles off. T. returns a member to Parliament. Pop. (1871) 5734.

Thirst, a term used to denote the sensations arising from the want of fluid nutriment. These sensations are chiefly referred to the thorax and fauces, but the condition of T. is really one affecting the entire body. A proof of this is that while moistening the fauces temporarily relieves T., it is permanently relieved by the introduction of liquids into the blood, either through the stomach or by direct injection into the blood-vessels. The excessive pains of T. compared with those of hunger are due to the fact that the deprivation of liquids is a condition with which all the tissues sympathise, so to speak. Every solid and every fluid of the body contains water, and hence abstraction or diminution of the watery constituents of the blood is followed by a general depression of the entire system.

Thirty Years' War, The, had its origin in the feeble efforts of Ferdinand I. to conciliate and of Rudolf II. to crush the Protestants, in the rise of the Jesuits to power, and in the formation of the Protestant Union by Christian of Anhalt and of the Catholic League by Maximilian of Bavaria, which divided Germany into two hostile camps. The violation of Rudolf's concession of religious liberty by Ferdinand II. (q. v.) led the Bohemians to elect in his stead Friedrich V. of the Palatinate, and the great drama opened, whose acts with their chief actors were as follows:—*Bohemian War* (1618-20), with Tilly (q. v.) *versus* the 'Winter King;' *War of the Palatinate* (1621-24), with Tilly *v.* Mansfeld, Friedrich of Baden, and Christian of Brunswick; *Dano-Saxon War* (1624-30), with Tilly and Wallenstein (q. v.) *v.* Mansfeld and Christian IV. (q. v.) of Denmark; *Swedish War* (1630-32), with Tilly and Wallenstein *v.* Gustaf Adolf (q. v.) of Sweden and Bernhard of Weimar; *Franco-Swedish War* (1632-48), with Ferdinand III. (q. v.), Wallenstein (till 1634), the Elector of Bavaria, and the Elector of Saxony (from 1635) *v.* Oxenstjerna (q. v.), Bernhard, Georg of Brunswick-Lüneburg, Richelieu (q. v.), Condé (q. v.), and Turenne (q. v.). The strife, which ruined the Holy Roman Empire and cost the lives of two-thirds of the German population, was ended by the unsatisfactory Peace of Westphalia, 24th October 1648. By it religious equality was established and Church property left as prior to 1624; the independence was recognised of Switzerland and the United Provinces; France received Austrian Elsass, and was confirmed in the possession of Metz, Toul, and Verdun; Sweden, acquiring Wismar and Stettin, Western Pommern, and the sees of Bremen and Verden, became a member of the German Diet; and the Electors of Bavaria and Brandenburg were largely profited. See, besides the histories of Schiller (2 vols. 1808-9), Söltl (3 vols. 1840-43), Gindely (3 vols. Prague 1869-78), &c., Gardiner's *T. Y. W.* (Lond. 1874), Charvériat's *Histoire de la Guerre de Trente Ans* (Par. 1878), and Ritter's *Brief- und Acten zur Geschichte des dreissigjährigen Krieges* (4 vols. Mun. 1878).

This'tle is the name given to a number of plants of the *Cynareæ* tribe *Compositæ* which have spinescent bracts and spinous-toothed leaves. The genus *Carduus*, with its subgenera *Cirsium* or *Cnicus* and *Silybum*, contains the greater number of those commonly recognised. This genus numbers about 160 species of erect herbs with heads of purple or white tubular flowers surrounded by many imbricated, appressed, narrow, rigid, acuminate, or spinous-tipped bracts, and usually bearing spinous-toothed leaves. The genus is chiefly confined to Europe and W. Asia, although some of the species have been accidentally introduced into other regions. Twelve are natives of Britain. Of these the most common are the spear T. (*C. lanceolatus*), a stout plant of 3 to 4 feet high, with leaves, bracts, and winged-stem bearing strong spines; it is abundant in waste ground; *C. arvensis*, the very common creeping T. of fields and roadsides, and a great pest of agriculture; and *C. palustris*, a stout biennial species of wet meadows, ditches, &c., with a winged-stem 2 to 4 feet high (formerly eaten). The musk T. (*C. nutans*), with large solitary hemispheric drooping heads of crimson flowers having a musky smell, is locally plentiful in waste ground; so also is *C. crispus* on dry banks, &c.; *C. tenuiflorus* in sandy places near the sea; and over a less area the stemless T. (*C. acaulis*), and the *C. pratensis* in boggy meadows. The tall, handsome, woolly-headed T. (*C. eriophorus*), with heads 2 to 3 inches in diameter, though widespread in Europe, is rare as an English plant, being mostly confined to limestone soil; its young parts are eatable both as salad and cooked. The conspicuous melancholy T. (*C. heterophyllus*) of moist sub-alpine pastures was formerly used for hypochondria. *C. Marianus*, the milk T., a glabrous plant having large white-nerved leaves with strong spines, globose heads of rose-purple flowers, with a long terminal spine to each bract, is common in S. and middle Europe. It also bears the name of 'Our Lady T.,' from the legend of the leaves being marked white by her milk. The blessed or holy T. is *C. benedictus*, a native of the Orient, but now widely distributed. It was long held in esteem as a tonic, diaphoretic, antidote against venom, &c. In genera held by botanists as distinct from *Carduus*, the name cotton T. is adopted for *Onopordon Acanthium*, a stout hoary or cottony biennial 4 to 5 feet high, commonly called by Scotch gardeners the Scotch T. The Carline T., or *Carlina vulgaris*, is frequent in dry sandy pastures and coast ground.

Carduus Marianus.

This'tle, Order of the, or of St. Andrew, a Scotch order of knighthood, instituted by James VII. (II. of England), May 29, 1687. It fell into abeyance in the reign of William and Mary, but was revived by Queen Anne, December 31, 1703.

This'tlewood Conspir'acy, a conspiracy formed in London in 1820 to assassinate the ministers of the Crown at a cabinet dinner, and excite an insurrection in the city, so called from the name of its ringleader, Arthur Thistlewood, a profligate whom ill-fortune had rendered desperate. The plot was discovered by a government spy, and the conspirators were seized in a garret in Cato Street, February 23, the day fixed upon for the execution of the project. Thistlewood and four others were executed, May 1, 1820.

Tho'len, an island of the Netherlands, in the province of Zeeland, lying N. of the Ooster Schelde. Area, 51 sq. miles; pop. 11,600. T. has a rich soil, and is protected by dykes. Wheat, rye, barley, oats, flax, madder, beans, and potatoes are its products. T., the chief town, has a pop. (1877) of 2741.

Tho'luck, Friedrich August Gottreu, a German Protestant theologian, was born at Breslau, March 30, 1799. He studied Oriental literature and theology at the universities of Breslau and Berlin, at which latter place he was appointed extraordinary professor of theology in 1824. In 1826 he was appointed ordinary professor at Halle, a post which he filled with usefulness and honour for half a century. He died 10th June 1877. T. wrote a large number of works, principally on theological

subjects. The chief are *Suffismus sive Theosophia Persarum Pantheistica* (Berl. 1821); *Blütensammlung aus der Morgenländischen Mystiker* (1825), *Wahre Weihe des Zweiflers* (1823, 9th ed. 1870), *Auslegung des Briefes an die Römer* (Berl. 1824), *Praktische Commentar zu den Psalmen* (Ham. 1843), *Philosophisch-Theologische Auslegung der Bergpredigt*, an exposition of the Sermon on the Mount (5th ed. Gotha 1872), *Glaubwürdigkeit der Evangelischen Geschichte* (Hamb. 1837), a reply to Strauss's 'Leben Jesu,' *Vermischte Schriften* (2 vols. Hamb. 1839). T. also wrote several volumes on the history and doctrines of the Lutheran Church, part of a history of Rationalism, and a number of sermons (5 vols. Gotha 1863–64), which are distinguished by a fervid though somewhat diffuse and even turgid eloquence. His most widely-circulated work was his *Stunden der Christlicher Andacht* (Hamb. 1840, 8th ed. Gotha 1870; translated as *Hours of Christian Devotion*, by Menzies, Edin. 1870). A complete edition of his works appeared at Gotha (11 vols. 1863–67). T. was a man of very wide rather than very deep learning. He preferred the general study of the whole vast field of theology to confining himself to a particular portion of it. He was for long the acknowledged leader of the orthodox party, a post for which a rare combination of piety, knowledge, and benevolence of disposition admirably fitted him. He was not above learning from his opponents, and in later life especially he no longer held by the extreme positions of the old school. For English translations of T. see Clark's *Biblical Cabinet*, vols. ii., v., vi., xii., xx., xxviii., xxxviii., xxxix., and Clark's *Foreign Theological Library*. See Kähler, *A. T., ein Lebensbild* (Halle 1877).

Thom, James, a self-taught sculptor, was born in Ayrshire in 1799. While still an obscure stone-cutter, he suddenly became famous by a group representing 'Tam o' Shanter and Souter Johnny,' and cut in the common sandstone on which he was accustomed to work. It is a miracle of dramatic vigour and artistic skill. This group, which now adorns the 'Burns Monument' at Doon, near Ayr, was first exhibited in Edinburgh in November 1828. Orders flowed in on the gifted sculptor, who removed to London, whence in 1837 he sailed for the United States, where he settled, and where his genius found a liberal recognition. T. died of consumption at New York, 17th April 1850.

Thom, William, a humble but genuine Scottish poet, was born in Aberdeen in 1799. His life is a sad record of unavailing struggles with miserable poverty. Sent to earn his bread in a factory at the age of ten, he became, after a four years' apprenticeship, a weaver in his native town, and worked there for seventeen years. Then he removed to Newtyle in Forfarshire. In 1837 some great failures in America caused the stoppage of 6000 looms in Dundee and the villages round about. T. was forced to wander about with a young family, 'houseless and penniless, deriving his only subsistence from his flute.' During a dismal expedition through Fife in search of work, one of his children 'died from want in an unsheltered outhouse.' At last he found employment at Inverurie. While here he wrote his *Mitherless Bairn*, a poem which is instinct with a deep feeling for cheerless misery, and which has drawn tears from the coldest hearts. T. died at Hawkhill, near Dundee, February 28, 1848. His poems were collected and published in one volume in 1845; a new edition is promised (1879) by Gardner of Paisley.

Thom'as, St. See St. Thomas.

Thom'as, George Henry, a distinguished general in the American Civil War, was born in Virginia, July 31, 1816. In 1836 he became a cadet at the U.S. Military Academy, graduated there in 1840, after which he served in Florida against the Indians, in the war against Mexico, and for five years in Texas. In November 1860 he returned to the East, and on the outbreak of the Civil War immediately placed his sword at the service of the Federal Government. He commanded a brigade at the battles of Martinsburg (July 3, 1861) and Bunker Hill (July 15). In November he received a command in the army of the Ohio, and contributed greatly to the important victory at Mill Springs (January 19–20, 1862). On the advance into Kentucky, he was appointed second in command of the army of the Ohio, and led the right wing in the battle of Perryville (October 8). During 1863, in the battle of Murfreesboro', T. led the centre of the army under General Rosecranz, and at the battle of Chickamauga he sustained a five hours' struggle against overwhelming forces, and alone prevented the defeat of the Federal army. On October 27 he received his commission as brigadier-general in the regular army, and during the campaign of 1864 he served under General Grant. On the 27th September of that year he was placed in chief command in Tennessee, where he was successful in out-manœuvring General Hood, and inflicting a severe defeat upon him at Franklin (November 30). On the 15th and 16th December he completely defeated Hood, destroying his army, for which he was thanked by Congress and voted a gold medal by the State of Tennessee. In 1869 T. commanded the military division of the Pacific, with headquarters at San Francisco, where he died, March 28, 1870.

Thom'as, Christians of St., are a community which existed in India, on the Malabar coast, from a very early date. According to tradition, the gospel was preached in India by St. Thomas the Apostle; but this Christian community was probably founded by refugees from the persecution which took place after the settlement of the Monophysite (q. v.) controversy in the 5th c. When the Portuguese arrived in India (1598) they found the C. of St. T. governed in temporal as well as in spiritual matters by the bishop of Angamala, who claimed the title of Metropolitan of India, and had actually the oversight of 1400 churches and a population of 200,000. They used the Syriac liturgy, and regarded themselves as the spiritual subjects of the Jacobite patriarch of Antioch. They stoutly maintained their peculiar (Nestorian, q. v.) opinions notwithstanding all the zeal of the missionaries who flocked in the rear of the Portuguese, and in consequence suffered much persecution at the hands of the Jesuits. They were nominally united with the Church of Rome in 1599, and remained so for sixty years till the Portuguese were expelled by the Dutch, when they returned to their ancient creed and worship. In 1830 there was a remnant of 60,000 or 70,000, but as they have been diligently attacked since then by the Church of England and other missionary societies, their peculiarities are rapidly being obliterated. See Geddes, *Hist. of the Malabar Church* (Lond. 1694).

Thoma'sius, Christian, a famous German jurist, was born at Leipzig, January 1, 1655, entered on a course of study there at the age of fourteen, from which he passed in 1675 to the study of philosophy and law at Frankfurt, where he graduated as doctor in 1679. After a short residence in the Netherlands, he returned to Leipzig to prosecute the profession of an advocate, but was soon afterwards called to a chair in the university. In his lectures he boldly declared war against the puerility and pedantry of the old methods of teaching, while in 1687 he introduced the startling innovation of reading his lectures in the vulgar tongue. The boldness of his attacks, and the powerful sarcasm with which he punished his opponents, procured him many enemies, whom his monthly review, *Freimüthige, lustige und ernsthafte, jedoch vernuft- und gesetzmässige Gedanken, oder Monatsgespräche über allerhand vornehmlich aber neue Bücher*, (commenced 1687), gave him a means of chastising. At last he was compelled to leave Leipzig and seek an asylum at Berlin. He was kindly received by Friedrich III., the great Elector of Brandenburg, and appointed to a lectureship in the Ritterakademie at Halle. On the establishment of the university at Halle in 1694, T. received the chair of jurisprudence, which he retained until his death, September 23, 1728. T. exercised an important influence on the German mind of his own day, and gave the deathblow to the pedantic terminology by which jurisprudence had been obscured. He insisted particularly on separating natural right from morality, and vigorously opposed trials for witchcraft and punishment by torture. Of his numerous works the most important are *Einleitung zur Vernuftlehre* (1691), *Einleitung in die Sittenlehre* (1692), *Natur- und Volkerrecht* (1705), *De Crimine Magiæ* (1701), and *Lehrsätze vom Laster der Zauberei* (1704). See Luden, *Chr. T. nach seinen Schicksalen und Schriften* (Berl. 1805); and B. A. Wagner, *T., ein Beitrag zur Würdigung seiner Verdienste um die deutsche Literatur* (Berl. 1872).

Tho'mists. See Aquinas.

Thom'pson, Thomas Perronet, was born at Hull, England, in 1783, and in 1798 entered Queen's College, Cambridge, where he graduated B.A. in 1802. After a short time spent in the navy, he entered the army and saw some service abroad, being

governor of Sierra Leone from 1808-12. After brilliant service in the Peninsular campaigns from 1812-15, and in India from 1815-21, he returned to England, left the army with the rank of lieutenant-colonel, and appeared as a political writer of advanced views. He advocated the repeal of the corn-laws, and co-operated in the establishment of the *Westminster Review*, besides publishing several treatises on music and geometry. In 1829 he retired on half-pay as lieutenant-colonel. He became M.P. for Hull, 20th June 1835, and for Bradford, March 1857. He died September 6, 1869. His chief works are, *Corn Law Catechism* (1827); *Enharmonic Theory of Music* (1829); *Geometry without Axioms* (1830); *Exercises Political and Otherwise*, a collection of fugitive pieces made by himself (1843); *Catechism on the Currency* (1848); *Theory and Practice of Just Intonation* (1850).

Thom'son, Andrew, D.D., was born at Sanquhar, in Dumfriesshire, Scotland, July 11, 1779. In 1802 he became minister of the parish of Sprouston, in the Presbytery of Kelso; in 1808 he removed to Perth; in 1810 was presented to New Greyfriars', Edinburgh; and in 1814 was translated to the new church of St. George's in that city. He died February 9, 1831. T. was remarkable for his eloquence both as a preacher and a platform speaker; took an active part in church discussions, more particularly in regard to the *Apocrypha;* worked hard in his parish for the improvement of the education of the poorer classes; founded and edited the *Christian Instructor;* and contributed a number of articles to Brewster's *Edinburgh Cyclopædia*. A vol. of his *Sermons and Sacramental Exhortations* was published in 1831, with a memoir prefixed.

Thom'son, James, an English poet, was born September 11, 1700, at Ednam, a village not far from the town of Kelso, in Roxburghshire. Intending to follow his father's profession, he began to study divinity at the university of Edinburgh, but his purpose gradually changed, and in 1725 he made his way with fortunate presumption to London as a candidate for poetic fame. His first volume was *Winter* (1726), and though it brought him no more than three guineas of immediate gain, it laid the foundation of his success. *Summer* followed in 1727, and *Spring* in 1728; and in 1730 there appeared the first complete edition of *The Seasons*, which has ever since maintained its position as the finest example of purely descriptive poetry in the language. It was during these same years that he produced *Britannia* (anonymous 1729), the tragedy of *Sophonisba*, and the poem to the memory of Congreve, which was recovered by H. F. Carey and printed by the Percy Society in 1843. By the recommendation of Dr. Rundle, afterwards bishop of Derry, he was appointed travelling tutor to Charles Talbot, eldest son of the Lord Chancellor; and the political observations which he made on his tour through Europe furnished him on his return with the materials of an unsuccessful poem on *Liberty* (1735). His services to Talbot were rewarded by the office of secretary of briefs; and though he lost his appointment on his patron's death, the deficiency was soon made up by a pension of £100 a year from Frederick, Prince of Wales; and at a later date he was allowed, through Lord Lyttleton's influence, to draw a considerable salary as surveyor-general of the Leeward Isles, while the duties of the surveyorship were discharged by a deputy. Between 1737 and 1740 he wrote a poem in memory of Lord Talbot, edited his own works, furnished a preface to Milton's *Areopagitica*, produced the tragedy of *Agamemnon*, and assisted Mallet in that *Masque of Alfred*, which has become memorable as the source of the national anthem, *Rule Britannia*. In 1745 he brought out the play of *Tancred and Sigismund*, founded on a story in *Gil Blas;* and in 1748 he published his *Castle of Indolence*. This last poem is T.'s most perfect work in point of poetic workmanship, and it proved almost his final effort, for he died at Richmond, August 22, 1748, leaving behind him only the scarce-completed tragedy of *Coriolanus*. In spite of the reputation for indolence which he arrogated and in some sort deserved, in his own department T. was a steady worker; but if it had not been for *The Seasons* and the *Castle of Indolence* his position in our literature would have been a very secondary one. His tragedies are well-nigh forgotten; though the name of *Sophonisba* is probably destined to echo back *Jemmy Thomson* as long as English literature survives. His style is unique, rich, elaborate, and sonorous, with a tendency to grandiloquence which is sometimes carried to gross and grotesque excess. He was a firm believer in 'poetic diction,' and when his heroine takes off her stocking she 'draws the inverted silk.' But flaws of this kind are forgotten in the general effect of his pictures, which are boldly conceived and powerfully drawn. *The Seasons* have been translated into French verse by J. Poulin (Par. 2 vols. 1802), and into German by Soltau (Bruns. 1823, and Bruckbrän Munich 1836). See Lives by Murdoch (1762), Allan Cunningham, and Sir H. Nicolson, the *Miscellanies of the Philobiblon Society*, 1857-58, and an essay by Barante in *Études Hist. et Biogr.* (Par. 1857).

Thom'son, Rev. John, a Scottish landscape-painter, was born in the manse of Dailly in Ayrshire, September 1, 1778. It was in vain that the boy artist pleaded with his father to let him become what nature had made him: he was destined for the church; and so, after studying at the University of Edinburgh, he was duly admitted to the practice of the clerical profession. In 1800 he was appointed his father's successor, and in 1805 he obtained the parish of Duddingstone, near Edinburgh. While a divinity student he had taken lessons in his favourite art from Alexander Naysmith, and he now prosecuted it with such success, that before long he was admitted an honorary member of the Royal Scottish Academy, and found so great a demand for the productions of his pencil, that his annual profits as an artist amounted to £1800. His favourite subjects were castles such as Craigmillar, and Highland scenes such as the Trossachs and Loch Achray. Not only were Sir Walter Scott, Sir Thomas Dick Lauder, and other Scottish celebrities, well-known visitors at the Duddingstone manse, but Turner and other English artists were among the rarer guests. T. died 27th October 1840. His elder brother, **Thomas T.**, also born in the manse of Dailly, 10th November 1768, studied at Glasgow, passed advocate at Edinburgh in 1793, held the office of deputy clerk-registrar (instituted 1806), did good service under the Record Commissioners, edited a number of works for the Bannatyne Club, and contributed to the *Edinburgh Review*. In 1828 he was appointed one of the principal clerks of the Court of Session. He died at Shrubhill, Leith Walk, Edinburgh, 2d October 1852. The list of T.'s publications, given in the *Scottish Nation*, shows the extent and nature of his historical and legal archæology. A sketch of his Life was published by the Bannatyne Club in 1853.

Thom'son, Sir Charles Wyville, F.R.S., an eminent zoologist, was born at Bonsyde, Linlithgowshire, Scotland, March 5, 1830. He began the study of medicine at Edinburgh University in 1845, became lecturer on botany at King's College, Aberdeen, in 1850, was elected professor of natural history at Queen's College, Cork, in 1853, and in 1854 settled at Belfast as professor of mineralogy and geology in Queen's College, a chair which he afterwards united with the natural history chair vacated by Dr. Dickie in 1860. In 1870 he succeeded Allman in the zoology chair at Edinburgh University. He early directed his attention to the lower forms of animal life. The discovery, by G. O. Sars in 1864, of a new *Crinoid* at a depth of 700 feet, convinced T. that the accepted theory that life did not exist in deep water was not by any means established. To settle this point he has taken a leading part in the dredging operations of the government vessels, the *Lightning* (1868), the *Porcupine* (1869-70), and the *Challenger* (1872-76). Besides demonstrating the existence of life at all depths, these expeditions, especially the last, have added many new species of animals, and increased our knowledge of the physical characters of the great oceans. T. was knighted shortly after the return of the *Challenger*. He has written valuable papers on zoological subjects, beautifully illustrated by his own most finished sketches, and is author of *The Depths of the Sea*, giving an account of his two first cruises, and the *Voyage of the Challenger*, the first and second volumes of which, published respectively in 1876 and 1878, treat of the Atlantic. The forthcoming third and fourth volumes are to deal with the Southern Seas and the Pacific.

Thom'son, Sir William, LL.D., D.C.L., F.R.S., perhaps the greatest natural philosopher which this century has produced, was born at Belfast, June 25, 1824. At the age of eleven he entered Glasgow University, where his father was professor of mathematics; and after finishing his course there proceeded to Cambridge, where he graduated in 1845 as second wrangler and First Smith's Prizeman, and was immediately after elected a fellow of his college (St. Peter's). Already he had written a series of remarkable papers on electrical distribution, which were published in the Cambridge *Mathematical Journal;* and in

1845, in a paper before the Royal Society, he pointed out that the experimental results of Snow Harris which were generally accepted as disproving Coulomb's laws of electrical action were on the contrary a strong proof of their truth. About the same time he developed the theory of electrical images; and attacked with great originality and success the subject of electrokinetics. The reputation which he thus early earned secured him the chair of natural philosophy at Glasgow University in 1846, a position which he still holds. His later career has more than fulfilled the promise of his early years; and to enumerate the subjects, experimental and theoretical, which he has elucidated, would carry us over the whole range of physics. Besides his researches in electricity already noticed, his thermodynamic work calls for special mention. In establishing and developing the true theory of heat, and in applying it to other departments of physics, T. holds a wholly unique position. The doctrine of the dissipation of energy (1852), and the discovery of the so-called Thomson Effect (1855), a result which, drawn from consideration of thermo-electric phenomena, was afterwards verified by experiment (see THERMO-ELECTRICITY), are his most important developments of the second law of Thermodynamics (q. v.). His theory of the origin of the solar energy, his calculation of the size of atoms, and his determination of the earth's rigidity, attest his extraordinary power of combining fact and theory to the working out of a given problem. The most wonderful, however, of all his theoretical researches is his vortex-atom theory, which, while explaining many of the properties of matter, has as yet been found inconsistent with none. A popular account of it is given in Tait's *Recent Advances*, and in Stewart and Tait's *Unseen Universe*. His mathematical insight is equalled by his experimental skill, as evinced by the verifications of his theoretical results; and as an inventor of delicate instruments of precision he has certainly never been excelled. His mirror galvanometer, his quadrant electrometer, his tide-gauge, his sounding apparatus, not to speak of his telegraphic transmitters and recorders, are amongst the more important of these. It is in this last connection, as a telegraphist, that T. is perhaps best known to the unscientific public. To him the possibility of submarine telegraphy is in great measure due; and for his exertions in laying the Atlantic cable, exertions which were at length crowned with success in 1866, he obtained the honour of knighthood. The siphon recorder and automatic curb-sender are his latest improvements in telegraphic apparatus. T. is also a skilful navigator; and his tables for using Sumner's method at sea afford a simpler and more accurate means for determining a vessel's longitude than is afforded by the usual methods. In this connection his mariner's compass merits special notice. Its peculiar advantages are steadiness and small frictional error, and the case with which it admits of the application of the corrections for the deviation due to the ship's magnetism, which were laid down by Archibald Smith and Airy. He is a member of the principal scientific societies at home and abroad, was President of the Royal Society of Edinburgh from 1873 to 1878, presided over the Edinburgh meeting of the British Association in 1871, and has been three times president of Section A of that body. His peculiar merit lies not so much in his great mathematical ability, as in the power with which he wields mathematics in purely physical questions, a faculty which is happily combined with a keen scientific insight and a rare experimental skill. His numerous memoirs are published in the *Philosophical Transactions* and the transactions of other societies, and also in the *Philosophical Magazine*, of which he is joint editor with Sir R. Kane and William Francis, Ph.D. With Professor Tait of Edinburgh he has projected an elaborate treatise on *Natural Philosophy*, to be published in four volumes (1 vol. 1867, 2d ed. expected 1879). His *Papers on Electrostatics and Magnetism* were published separately in 1872.—**James T., LL.D., F.R.S.**, an elder brother of the preceding, was born at Belfast about 1816. He graduated at Glasgow in 1837, settled at Belfast, where in 1857 he became professor of engineering at Queen's College, and in 1872 succeeded Rankine in the engineering chair at Glasgow. He has devoted much attention to drainage, irrigation, and agricultural engineering generally, and has invented various forms of turbines, pumps, &c. His deduction from theory of the lowering of the freezing point of water by pressure, experimentally verified by his more illustrious brother, has completely cleared up the long-debated question of glacier motion (see GLACIERS).

Thom'son, Thomas, was born at Crieff, in Scotland, April 12, 1773. After studying at the University of St. Andrews, he succeeded his brother, James Thomson, afterwards D.D., and minister of the parish of Eccles, Berwickshire, as editor of the Supplement to the 3d. ed. of the *Encyclopædia Britannica*, graduated in medicine at Edinburgh in 1799, and was for some years subsequent to 1802 scientific editor of James Mills' *Literary Journal*. He was the first to introduce the use of symbols in chemistry, and to announce Dalton's Atomic Theory, privately communicated to him in 1804, in the 3d ed. of his *System of Chemistry* (5 vols. 1807). In 1818 T. became Professor of Chemistry in the University of Edinburgh, and died at Kilmun, in Argyllshire, August 2, 1852. T. was a very voluminous writer. Besides the works already mentioned, and a vast number of papers in various philosophical journals, he published a *History of the Royal Society of London* (1812); a *History of Chemistry* (1830), and *Outlines of Mineralogy, Geology, and Mineral Analysis* (2 vols. 1836).

Thomson, William, D.D., born at Whitehaven, Cumberland, 11th February 1819, from Shrewsbury School obtained a scholarship at Queen's College, Oxford, and graduating B.A. in 1840, was elected fellow. Ordained in 1842, he preached the Bampton lectures for 1853 on *The Atoning Work of Christ*; in 1855 received the Crown living of All Souls, Marylebone, and the provostship of Queen's College; in 1861 was consecrated to the see of Gloucester and Bristol, and two years later translated to the archbishopric of York. His *Outline of the Necessary Laws of Thought* (1842, 10th ed. 1875) is a text-book in English-speaking universities, and he has further published *Sermons preached in Lincoln's Inn Chapel* (1861), *The Limits of Philosophical Inquiry* (1869), &c.

Thor (Old Eng. *Thunor*, Old High Ger. *Donar*), the son of Odin and Jörd, is in northern Mythology (q. v.) the highest of the Æsir after Odin. He is the strongest of all the gods, and defends Asgard and Midgard against the Jotuns. T.'s kingdom is called Thrudvangar; his palace, Bilskirnir, has 540 rooms, and is the largest in the world. He rides in a car drawn by two he-goats amid thunder and lightning. His mailed hands grasp the hammer Mjölnir, well known of the Jotuns, for many of their skulls has it crushed. When he girds on his Belt of Strength his power is doubled. His wife is called Sif, and his sons are named Modi and Magni.

Thora'cic Duct, the name applied to the tubular structure in which the *absorbent system* of vessels may be said to terminate, and into which the *lacteals* of the intestine ultimately pour their contained fluid. The T. D. thus receives (1) the products of digestion or *chyle* from the lacteal vessels of the intestine, and (2) the *lymph* or fluid, brought as the elaborated waste-matters of the body from the tissues by the *absorbent system* of vessels or *lymphatics*. Being poured into the T. D., these products, which are destined to replenish the blood, and thus renovate the tissues, are in due course poured into the circulation. The T. D. of man exists as a tubular structure attaining a length of about 18 or 20 inches. It extends from the second lumbar vertebra to the root of the neck, where it ends in the angle formed by the junction of the left internal jugular and subclavian veins, into which vessels its contents are therefore poured. At its commencement in the abdomen it exhibits a dilatation, termed the *receptaculum chyli*, which receives the lymphatics of the lower extremities. The T. D. has a flexuous course, and exhibits an irregular or contracted appearance. It is provided internally with valves, preventing the backflow of its contained fluid. Occasionally it divides above into two branches; and a *right T. D.* is normally found as a short trunk attaining about an inch in length, and devoted to the reception of the lymph from the right side of the head and neck, from the right side of the chest and heart, and from other regions on that side of the body. In birds, the right T. D. may be equally developed with that of the left side.

Thor'ax (Gr. *thōrax*, 'a breastplate'), the name applied to that cavity in vertebrate animals formed by the spine, ribs, and breastbone, and in insects and other Arthropoda to the segments intervening between the head and abdomen. In insects the T. is free and consists of three joints. In spiders and Crustaceans the T. is amalgamated with the head to form the *cephalo-thorax*. In Mammalia the T. is completely shut off from the abdo-

men by the *diaphragm* or *midriff*, while in birds and lower vertebrates the T. may be very ill-defined, and freely communicates with the abdomen. In serpents the chest or T. is not completed below by a breastbone, and in fishes also there is no breastbone. In Amphibians (*e.g.*, frogs) in which ribs are wanting a T. may be said to be unrepresented. The T. of man and higher animals is lined by the delicate nervous membrane known as the *pleura*. It contains the heart and lungs as its chief viscera, the main bloodvessels of the body, as also the *œsophagus* or gullet and the *Thoracic Duct* (q. v.) also traversing its extent.

Thor'burn, Grant, born near Dalkeith, Midlothian, February 18, 1773, was in early life a nailmaker, and on account of political troubles removed to New York in 1794. After a chequered career, he became a successful seedsman, and as 'Lawrie Todd' a voluminous writer for periodicals. He acquired a high character for practical benevolence; and the nobility of his disposition, and strange vicissitudes of his life, are faithfully reflected in Galt's novel of *Lawrie Todd* (1830). His works include *Forty Years' Residence in America* (1834), *Men and Manners in Great Britain* (1834), *Fifty Years' Reminiscences of New York* (1845), and *Life and Writings of G. T., Prepared by Himself* (1852). He died at New Haven, January 21, 1863.

Thor'burn, Robert, a Scottish painter, was born at Dumfries in 1818, studied at the Edinburgh Academy from 1833, and three years later proceeded as a miniaturist to London, where he rapidly rose to fame. He adopted a largeness of size as well as of style unusual in miniatures, and in aiming at the higher qualities of oil-painting lost none of the purity, brightness, and transparency peculiar to able paintings on ivory. For many years his portraits, on account of their art not less than the eminence of their subjects, were among the most attractive works exhibited at the Royal Academy, while the long roll of his illustrious sitters included the Queen, the Prince Consort, and many members of the royal houses of France, Germany, Belgium, &c. T. was particularly happy in the treatment of female beauty. He was made A.R.A. in 1848, and died 19th November 1863.

Thor'eau, Henry David, born in Boston, July 12, 1817, graduated at Harvard in 1837, and was a schoolmaster till 1840. An abolitionist who had run into perils by his efforts against slavery, an ardent naturalist, 'who knew,' says his friend Emerson, 'the country like a fox or a bird,' he withdrew in 1845 to a hermitage, built by himself in Walden Wood, and there for two years lived at an annual cost of $70. From this solitude T. emerged to pursue his father's calling of pencil-making at Concord, where he died 6th May 1862. Besides contributing to the *Dial*, *Atlantic Monthly*, and other periodicals, T. published *A Week on the Concord and Merrimack Rivers* (1849) and *Walden, or Life in the Woods* (1854); while after his death appeared *Excursions in Field and Forest* (1863), *Cape Cod* (1865), *A Yankee in Canada* (1866), &c. See W. E. Channing, *T., the Poet-Naturalist* (1873), and Page, *T., his Life and Aims* (1877).

Thor'inum or **Thor'ium** (Th = 23·15), a rare metal, belonging to the aluminum group, and discovered by Berzelius (1828) in thorite. The oxide *thorina* seems to have the constitution ThO, in this differing from alumina, from which it is physically distinguished by its insolubility in the alkalies. The sulphate is sparingly soluble in hot water, from which it is precipitated on boiling. The chloride ($ThCl_2$), a white shining crystalline substance prepared by sublimation of an intimate mixture of thorina and carbon in chlorine, forms double salts with the chlorides of the alkali metals.

Thorn (Pol. *Torun*), a town of Prussia, province of W. Prussia, near the Russo-Polish frontier, on the river Vistula, 115 miles N.W. of Warsaw by the Bromberg-Warsaw railway, is strongly fortified. In the Johanniskirche there is a monument to Copernicus, who was born here. T. was formerly a Hanse town, and has still many houses with fine interiors in the old Hanseatic style. It has steamboat communication by river with Danzig, Stettin, and Berlin. The chief industries are leather and tobacco manufactures, and there is a large trade in timber and corn. Pop. (1875) 18,631. See Zernecke, *Thornische Chronica* (T. 1711 and 1727); Wernicke, *Geschichte T.'s* (T. 1842).

Thorn. See CRATÆGUS, HAWTHORN, and SPINE.

Thorn-Apple (*Datura*), a genus of poisonous *Solanaceæ* (q. v.), with a funnel-shaped, angular, five-lobed corolla, and a four-valved capsular fruit with four compartments. *D. Stramonium*, the best-known species, occurs sporadically in many parts of the globe, appearing in England occasionally as a casual weed on rubbish-heaps and rich waste ground. Gerard mentions in 1599 having received seeds of it for his London garden from Constantinople. It is a coarse, heavy-smelling, wide-spreading annual, with ovate, sinuate, glabrous leaves, large white flowers in the forks of the stem, and ovate, many-seeded capsules, covered with triangular prickles—whence the name T.-A. The ripe seed and leaves are used medicinally in sciatica, lumbago, chronic rheumatism, and other painful diseases, and the leaves are recommended for smoking in asthma. Leaves, flowers, and rootlet-rind are, according to Captain Burton, smoked by Arabs of Central Africa as a sovereign remedy for a like purpose. The active principle is an alkaloid named *daturia*. In India the seeds of *D. fastuosa* are employed as means to commit theft, and also with other criminal intentions; in Ceylon they are generally given to the victim in arrack: the symptoms that ensue are vomiting and a sinking into a state of lethargy, in which state the person sometimes remains for one or two days. *D. alba* or *D. metel* produces similar narcotic, anodyne, and poisonous effects. The Peruvians prepare an intoxicating and delirium-producing beverage from the seeds of *D. sanguinea*. Beautiful arborescent species of *Datura* (or *Brugmansia*) from S. America are cultivated for their ornamental appearance, such as *B. suavolens*, with large fragrant white blossoms, and *B. bicolor* with orange or scarlet ones.

Thorn'back (*Raia clavata*), a species of Ray, so named from the conspicuous row of spines which arm its back and tail. The T. is common on British coasts. It attains a length of 2 feet or more, and is of a brown colour marked with lighter spots above, and white below. The body nearly approaches the rhomb in form, and the muzzle is by no means prominent. The flesh of the T. is somewhat coarse, but nutritious.

Thorn'bury, George Walter, born in London in the autumn of 1828, for a short time studied painting, but ultimately devoted himself to letters, contributed a series of papers on topography to the *British Journal* (1845), and to the *Athenæum* (1851) some chapters on the Crystal Palace, afterwards republished. His works of the next twenty years—a library in themselves—include *Monarchs of the Main* (1855), the fiery *Songs of the Cavaliers and Roundheads* (1857), *Life in Spain* (1859), *Turkish Life and Character Illustrated* (1860), a *Life of Turner* (1861; new ed. 1877), *Wildfire* (1864) and other novels, *Haunted London* (1865), *Criss-Cross Journeys* (1873), and a finely illustrated selection of his *Legendary and Historic Ballads* (1873). Essayist, novelist, lyrist, biographer, traveller, and art-critic, T. was also a successful lecturer; but sank under overwork, and died 11th June 1876.

Thorn'headed Worms, or **Acan'thoceph'ala**, a group of *Scolecida* (q. v.) allied to the *Nematoid* (q. v.) worms, and so named from the armature of the head. They are internal parasites, possessing neither mouth nor digestive system, and having a proboscis armed with hooks. The sexes are distinct. The only distinct genus of T. W. is *Echinorhynchus*, the species of which, in a fully-grown condition, inhabit the digestive system of vertebrates, and occur in fishes, birds, and mammals. The young undergo a metamorphosis. Thus the embryos of *E. gigas*, which inhabit the pig's intestine, are found in the larvæ of the cockchafer.

Thorn'hill, Sir James, an English painter, born in 1676 at Woodland, Dorsetshire, studied his art in Flanders, Holland, and France, and in the school of Le Brun acquired a taste for mythological allegories and lavish ornament. On his return to London his style soon became fashionable, and his brush was in constant request. He spent nineteen years in 'adorning' the great hall of Greenwich Hospital with a representation of 'William the Third giving Peace to Europe,' and surrounded by Queen Mary, the Virtues, Apollo, the Four Seasons, &c.' Among his other works are the decoration of the dome of St. Paul's Cathedral with eight episodes from the life of the Apostle, the decoration of a saloon in Blenheim House, and another at Hampton Court, besides the large pictures he executed at Moor Park. He was knighted by George I. in 1715, and sat in Par-

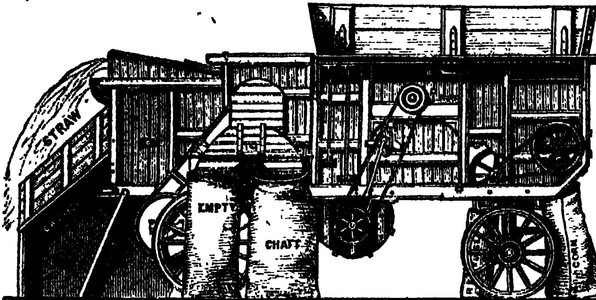
liament for his native borough from 1719 till his death, which took place at Weymouth 4th May 1734. His daughter Jane became the wife of the illustrious Hogarth.

Thorough Bass. See FIGURED BASS.

Thorp, the Scandinavian equivalent of the Ger. *dorf*, 'a village,' in local nomenclature sometimes stands by itself, *e.g.*, Le Torp, in Normandy; but oftener appears as a suffix, as in Eng. Althorpe, Wilstrop, and Nor. Clitourps. Being Danish rather than Norwegian, this suffix often helps us to determine whence Scandinavian settlers arrived in England; and whilst it is very common in E. Anglia, it occurs very seldom in Westmoreland, but once in Cumberland, and never in Lancashire.

Thorwald'sen, Albert Bertel, the eminent Danish sculptor, was born near Copenhagen, 19th November 1770. His parents were very poor, and he did not receive even the rudiments of an ordinary education. At an early age he entered the Art Academy, where he gained the highest honours. In 1796 he obtained a travelling government pension of £24, and started for Rome. He went by sea, and the voyage took the almost incredible period of eight months, which T. spent in eating, smoking, and sleeping. He refused offers of Italian lessons, and reached Rome quite ignorant of the language, but even his sluggish soul could not resist the influences of the southern sky, and the memories of the past which fill the Eternal City. To the sculptor these were more than memories, for the great works of art were present there, fresh and glorious as when they came from their creators' hands. 'I was born,' he said, 'on March 8, 1797' (the day he entered Rome); 'up to that time I did not exist.' For long he worked away without exciting much attention, till a figure of 'Jason' was noticed by Canova, and T. found himself famous. Still, he had no money, and was forced to prepare for his return home, when Thomas Hope, the English banker, came to T.'s studio, saw the statue, and ordered it to be executed in marble for himself. This was the turning-point in his career. Wealth and distinction flowed in upon him without ceasing, and when he returned to Copenhagen in 1819, the whole town went out to meet him and do him honour. Next year he was again in Rome, and here he remained till 1837, when he finally settled in Copenhagen, where he died suddenly while in the theatre, 24th March 1844. He left his large fortune, and all the works which were in his own possession, to his native town. A splendid museum was built to contain them, and here also the remains of the artist were laid. During a long work-time T. executed about '200 bas-reliefs, 100 busts, 15 portrait-statues, about 60 statues from mythological and Christian subjects, and 10 monuments for tombs.' Of his works, the following deserve special notice. His statue of 'Mercury,' a remarkably expressive and still more suggestive figure. 'The Triumph of Alexander,' a bas-relief intended to adorn the palace of the Quirinal, and which is considered his greatest work. A great variety of figures, representing very various phases of feeling, are introduced, but the joy of the conquerors and the grief of the conquered, while serving to give expression to the most varied feelings, both tend to the one idea of the work—the triumph of the youthful hero. Of his equestrian statues, that of the emperor Alexander at Vienna is considered the best. His decorations of the Frue Kirche at Copenhagen are his best efforts in Christian art. It only remains to mention his figure of the 'Dying Lion' at Lucerne, 'hewn out of the living rock,' a memorial to the Swiss Guards who fell on 10th August 1792. The grand simplicity of the figure, and the situation where it is placed, produce an effect that no spectator ever forgets. For T.'s life and works, see Thiele and Hillerup's *T. og hans Vaerker* (Copen. 1831-50, and 1851-56); Anderson's *Bert. T.* (Copen. 1845); an English *Life of T.*, by Barnard (Lond. 1865), chiefly an abridgment of Thiele; and *T., his Life and Works*, by Plon, translated by E. Hoey (Lond. 1874).

Thoth. See HERMES TRISMEGISTUS.



Thou (Lat. *Thuanus*), **Jacques Auguste de,** son of a first president of the Parliament of Paris, was born in that city, 8th October 1553. Educated at the Collége de Bourgogne, he studied law at Orleans, Bourges, and Valence; then returning to Paris, took orders and received a prebend of Notre Dame. In 1573 he travelled in Italy, in 1578 was appointed ecclesiastical councillor to the Parliament, and in 1581 was a member of a commission established under Séguier in Guienne, where T. held several interviews with Henri de Navarre, and was brought across Montaigne. Yielding to the pressure of his family, he renounced his orders, and having as a councillor of state (1588) aided the reconciliation between Henri III. and Henri de Navarre, he saw five years' campaigning with the latter. In 1593 he was appointed keeper of the royal library, and as a magistrate he zealously promoted the Edict of Nantes. On Henri IV.'s death T. aspired at the office of first president, and being merely summoned to the council of finance retired in chagrin from public life, and died 7th May 1617. T. was the author of an *Historia sui Temporis* (5 vols. 1604-20; best ed. Lond. 1733; Fr. trans. 1734 and 1759), which, covering in 138 books the period 1546-1607, is a laborious and truthful narrative, so strictly impartial that the papal censure placed it upon the *Index Expurgatorius*. His other works include *Thuani Commentarius de Vita sua* (1620; Fr. trans. 1711) and some excellent Latin poems. See the *Discours sur la Vie et les Ouvrages de T.* by Patin (1824), and Charles (1824); and Düntzer, *De T.'s Leben, Schriften, und historische Kunst* (Darms. 1837).

Thourhout' ('Thor's wood'), a town of Belgium, province of W. Flanders, 14 miles S.W. of Bruges by rail. It manufactures mustard, starch, sabots, hats, &c., and has a teacher's training-school. Pop. (1873) 7857.

Thrace (Gr. *Thraike*, probably from *tracheia*, 'rough') is a geographical term at first applied loosely to the whole of the mountainous region N. of Greece, but latterly confined to the district between the Danube on the N., the Euxine and Bosphorus on the E., the Propontis, Hellespont, Ægean, and the northern part of Macedonia on the S., and the Strymon and Illyria on the W. In the time of Philip II., and his son Alexander the Great, the boundary of Macedonia was advanced to the river Nestus, which henceforth marked the western limit of T., and by Augustus its northern boundary was withdrawn to the Hæmus (mod. Balkans), the region between which and the Danube being formed into the separate province of Mœsia. From the Hæmus three ranges extended southwards, of which that furthest to the W. was named Pangæus, and that to the E. Rhodope; to the centre ridge no name is given. The Pangæus separated the valleys of the Strymon and Nestus; to the E. of Rhodope was the Hebrus. The soil of the more level portions was fertile, and notwithstanding the alleged severity of the climate, the vine was largely cultivated. Cattle were extensively reared, and horses, a white breed of which was famous. Gold and precious stones were found in some parts, the existence of which to this day is confirmed by the French traveller Viquesnel. Of history T. has almost none; it was nominally subdued by all the great nations who came in contact with it, Persians, Macedonians, and Romans, but only the last effected anything like a real conquest of it, while the versatile Greeks secured to themselves the best products of the country by means of their flourishing colonies of Amphipolis, Byzantium, Salmydessus, &c. Under the Turks the greater part of it was included in Rumelia (q. v.).

Thrash'ing, an operation which consists in separating ripened grain from the straw on which it grows. From the earliest times in eastern countries T. was effected by the treading of oxen and horses on the straw and grain spread out over a floor of hardened clay, whence the Scriptural injunction, 'Thou shalt not muzzle the ox when he treadeth out the corn' (Deut. xxv. 4). This primitive method of T. is still prosecuted in many warm countries, such as Spain, Italy, Turkey, &c., a twofold object being attained by this rude and uncleanly process, viz., the separation of the grain, and the bruising and softening of the straw, whereby it is rendered fit for cattle fodder. In colder regions, where the straw is not so hard, and where hay is cultivated for fodder, the flail was long the simple and sole T. implement, and in primitive localities in Scotland, &c., it may yet be seen in operation. The flail consists of two stout sticks, the hand-staff, and the swingle, loosely attached to each other by a very strong, tough, flexible band of eel-skin or gut. The workman holding the hand-shaft in both hands swings the implement over his head, bringing the swingle down horizontally on the sheaf-head, which is opened out on the barn floor. The process is very tedious, and altogether unsuited to the modern requirements of even a small farm. No means of superseding it, however, were effectively devised till about the year 1785, when Andrew Meikle, a millwright in Haddingtonshire, Scotland, invented the T. mill, which, with unimportant

modifications, is the mill now in common use. The principle of Meikle's T.-mill consists in the use of a *drum* with beaters, which in its rapid revolution strikes against the corn fed into it with great violence, and thereby detaches the grain. The modern Scottish T.-mill, which usually forms a part of every farmsteading, based on Meikle's principle, consists of the following essential parts:—(1) The feeding rollers, a pair of grooved rollers working into each other, through which the corn is entered to the drum lying immediately behind them. By these rollers the straw is partly held while it is subjected to the beating of the rapidly rotating drum. (2) The drum, a cylindrical framework on which four or more beaters, consisting of projecting iron-shod bars, are mounted. The drum is enclosed in a case and is rotated

Thrashing Machine.

at a high speed, the beaters moving, on an average, 3500 feet per minute. In this the grain is detached from the ear, and the whole passes on to (3) the shakers, where the mixed grain and straw are separated. The shakers consist of two cylinders like the drum, with rake-teeth instead of beaters. They revolve slowly, the first passing on the straw to the second, while grain, chaff, and broken straw fall through the grating under these parts of the apparatus. The clean straw is tossed out of the apparatus by the second shaker, and slides down a grid-formed incline of wooden bars. Under the shakers is (4) the hopper, which collects the grain, chaff, &c., and passes them on to (5) the mill fanners, in which a fan blast separates the grain from the chaff. A second dressing is usually given to the grain in (6) the second fanners. The T.-mill is worked either by horse, water, or steam power, according to circumstances.

The English portable steam T.-machine is much more widely used than modifications of Meikle's apparatus, and even in Scotland it is now much employed. The drum used in these machines differs in its action from that in the Scotch mill, acting by rubbing the grain against a grating fitted around it rather than by beating it when held by feeding rollers. There are, indeed, no feeding rollers in the machine, the corn being fed direct to the drum, which carries it forward and rubs out the grain. The straw is thrown on a series of reciprocating straw shakers, by which it is gradually carried forward, while grain, chaff, &c., are separated and are carried to the riddle board. The English T.-machine is capable of T. at a rapid rate, and performs its work in a most satisfactory manner. It requires, however, to be made in a very solid and workmanlike fashion; and several agricultural implement-makers have attained a high reputation for their machines. With a portable engine the machine can be moved from field to field, T. the grain where it grew, which is often a great convenience; and it, moreover, can be transported to the various farms in a wide district, performing in a few days all the T. work required for a whole season. Thus one machine may do efficiently and economically the work of T. for many farmers, and a stationary T.-mill, which at most is only required at infrequent intervals, is rendered unnecessary in a part of a farm furnishing.

Thrasybu'lus, a celebrated Athenian general and democratic leader in the latter part of the Peloponnesian War, first heard of (411 B.C.) as commanding a galley in the fleet at Samos, afterwards one of the most active in bringing about the downfall of the Four Hundred and the recall of Alcibiades. His close friendship with the latter involved him in his disgrace after the battle of Notium, and on the establishment of the Thirty Tyrants he was banished, and retired to Thebes. In 403 he entered Attica at the head of seventy other exiles, seized Pyle, and occupied the Peiræus, and ultimately forced from the oligarchical party a general amnesty. In 394 he commanded the Athenian armies in Bœotia and before Corinth, and in 390 was sent with forty ships to aid the Rhodians against Teleutias. He next sailed to Byzantium and reduced several of the islands, but while cruising on the Pamphylian coast he cast anchor in the mouth of the Eurymedon, and was murdered in his tent by the natives during the night (390).

Thread, a fine cord or twine used for sewing. The greater part of the sewing T. used is made from cotton yarn in twisting-mills, but much strong T. is also made of linen. The use of T. has enormously increased of late years, owing to the introduction of sewing-machines. Paisley, near Glasgow, is the great centre of the T. manufacture, in the enormous factories of which it is believed that more than half of the T. made in the United Kingdom is produced. Several of the Paisley T. manufacturers also own great establishments in the United States, and it is scarcely too much to affirm that nearly one-half of the T. trade of the world is in the hands of Paisley manufacturers.

Thread-Cells, the name given to certain peculiar cells or cysts, found chiefly in the tissues of *Cœlenterate* (q.v.) animals. They contain fluid, and are provided with an internal thread-like filament. Under pressure the cell ruptures, the thread is everted, and the fluid escapes. These cells form a poison-apparatus for paralysing prey.

Thread-Worms, the popular name of certain *Scolecida* (q. v.) belonging to the order *Nematoda*. The best-known genus is the *Oxyuris vermicularis*, or small T. W., which inhabits the rectum or lower bowel of children especially. Nearly allied to this is the larger *Ascaris lumbricordes*, or common round worm, found in the human intestines, in that of the pig, &c., and attaining a length of 6 inches. The average length of the Oxyuris is about ¼th of an inch.

Threat, in a legal sense, is the endeavour to make any one surrender a right or possession by means of intimidation. The endeavour to compel surrender of personal property by T. of personal violence is Robbery (q. v.). Regarding T. of accusation see EXTORTION. See also FORCE and FEAR.

Three Kings, Feast of the. See EPIPHANY.

Thrift, or **Sea Pink** (*Armeria*), a genus of perennial herbs belonging to *Plumbaginaceæ* (q. v.), differing chiefly from *Statice* (q. v.) in the flowers being collected into bracteated heads at the apex of the scape. All the leaves are radical and very narrow, the flowers arranged in cymes which are massed into a dense hemispheric head, calyx funnel-shaped and scarious, petals cohering at the very base. There are about thirty species occurring in Arctic, alpine, and maritime N. temperate regions, and exceptionally represented in Chili in the S. hemisphere. The common T. (*A. vulgaris*), a plant of the three northern continents and Chili, is very common around the British coast, appearing also on high mountains up to 3800 feet in Scotland. It has a strong, woody, branched rootstock, dense cushions of leaves in compact tufts, from which arise scapes of 3 to 12 inches, bearing heads of rose-pink or white flowers. The plant is commonly seen in small gardens, forming an edging to the flower-beds.

Thrips, a genus of *Hemipterous* insects, of which *T. cerealium* infests and injures wheat to a large extent. In the family *Thripidæ*, of which T. is a typical genus, the wings are abortive, the mandibles bristle-like, and the antennæ long and slender. In *T. cerealium* the females have a four-valved ovipositor or boring apparatus, for the deposition of eggs. The front wings are thick, and the antennæ are nine-jointed. The male is wingless. These insects infest the spathes or sheaths of grasses and cereals, and destroy the stem by puncturing it and causing effusion of the nutrient fluids.

Throat, Diseases of the. The D. of the T. met with in the practice of medicine do not differ materially from the diseases of other parts of the body. The most frequent form of sore throat is that of a simple erythematous inflammation. The mucous membrane of the pharynx, palate, and tonsils is congested and swollen, and the sub-mucous connective tissue may be greatly relaxed. There is usually more or less heat and dryness of the parts, difficulty in swallowing owing to the pain excited by the movement, and almost always some degree of fever, with

more or less acceleration of the pulse. The treatment of this form of sore throat is very simple. The patient should be confined to bed in order to secure rest and an equable temperature, which is of great importance. A gentle but efficient laxative should be given, and if the pain is severe and the pulse accelerated, a small quantity of morphia and aconite may be added to the aperient. The diet should be light and easily digestible, and the free use of demulcent drinks may be encouraged. The inhalation of steam will be of service in the acute stage, and if the membrane be very much relaxed, astringent solutions of alum, nitrate of silver, carbolic acid, or chlorate of potass, may be topically applied in the form of spray. In *phlegmonous sore throat* there is a higher grade of inflammatory action, the sub-mucous connective tissue being affected, and the tonsils are usually affected in a greater degree than the surrounding structures, the disease being designated *amygdalitis*, *quinsy*, or *tonsillitis*. *Ulcerated sore throat* is often described under the name of *angina maligna*, or *tonsillitis maligna*, and is usually attended with typhoid symptoms. It is occasionally attendant upon diphtheria, and sometimes follows scarlatina, measles, smallpox, dysentery, and enteric fever; more or less fever of a low type being always present. The pain is not so severe as in ordinary sore throat, but soon after the commencement of the affection the tonsils and the surrounding structures are seen to be studded with dark ash-coloured ulcers, which soon slough, and give forth a fœtid, ichorous, or sanious discharge. The disease is apt to extend to the upper part of the pharynx and to the nasal passages, but the larynx is seldom involved. In severe cases death may occur from syncope, coma, or from gradual exhaustion of the vital forces. *Membranous sore throat* is characterised by the exudation of a fibrinous material, which coagulates into a false membrane. This form of *sore throat* is often met with during the prevalence of Diphtheria (q. v.), and is by many physicians considered a mild form of that disease. Clergyman's *sore throat*, or chronic *follicular pharyngitis*, has been already described under Disease of the Pharynx (q. v.).

Thrombo'sis (Gr. *thrombos*, 'a clot of blood') is the term used to designate an affection of the blood-vessels which consists in a coagulation of blood, forming a true clot, at a certain fixed spot. A clot thus formed in a vessel increases and extends from one to another till it reaches and finally fills a large vessel.

Throndhjem (Ger. *Drontheim*), the third city of Norway, occupies the triangular peninsula of Nidarnæs, between the mouth of the Nidelve and the Thondhjemsfjord, 243 miles N. of Christiania. T. is regularly built of wood, and has broad streets. It is defended by the old fortress of Thunkholmen. Its chief building is the Cathedral of St. Olaf (1093-1300), where the kings of Norway are crowned. There are three other churches. T. is a bishop's see, has a grammar school and real school, a deaf and dumb institute, a theatre, the Royal Norwegian Scientific Society, with a large library, and the head office of the Bank of Norway. T. exports timber, oil, copper, dried fish, and herrings. In 1877 there entered and cleared 88 British ships of 21,102 tons. Shipbuilding, iron-founding, distilling, and the manufacture of leather and tobacco and machines, are carried on. T. was founded in 997 by Olaf Trygvesön under the name of Nidaros, and in the 12th and 13th centuries was the usual residence of the Norwegian kings. It suffered much from fires in 1532, 1841, 1842, and 1844. Pop. (1875) 22,000.

Throne (Gr. *thronos*, from *thraō*, 'I set'), the chair used on occasions of state by a king, emperor, or pope. It is usually raised, and often surmounted with a canopy. The term is also applied to the seat of a bishop in his cathedral church, and is a common metaphor to express sovereign power.

Throw, a mining term used very generally among geologists, signifies the amount of vertical displacement produced by a Fault (q. v.).

Thrush, the name given very generally to a large number of species of Insessorial birds included in the family *Turdidæ*, which in turn forms a sub-group of the *Dentirostres*. A special sub-family (*Turdinæ*) includes the more typical species known as T. The bill is stout and compressed, the upper mandible notched at its tip, and the 'gape' furnished with bristles. The third and fourth quills are the longest, and the toes are long and strong. Of the T. one of the best known is the Missel T. (*Turdus viscivorus*), which measures 10 or 11 inches, and is of a dull brown on the upper parts, and yellowish-white below, both surfaces being marked with black spots. The Missel T. begins its song, which is loud and clear, as early as February, and breeds in April. The Song T. (*T. musicus*) has a clear, sweet voice, and is popularly named the 'Throstle' from its singing powers, or in Scotland the 'Mavis.' The colour is brown marked with black above, and whitish yellow beneath. The length is 8 or 9 inches. The eggs usually number five, and are of a bluish tint, spotted with black. The bird may be successfully kept in captivity. The nest is usually built in the middle of a thick shrub, and the male takes part in incubation. The mavis remains throughout the year in Britain, and feeds on worms, snails, berries, seeds, &c. The Wood T. (*T. mustelinus*) is a N. American species, which migrates from N. to S. in winter. It is smaller than the others. In the W. Indies the T. is represented by the *T. leucogenys*, or 'Hopping Dick,' a bold and lively species of T., with a clear and brilliant song.

Thrush, Infantile Sore-Mouth, or **Diphtheria of the Mouth,** is essentially a disease of early infancy. It is very frequently met with in connection with the artificial feeding of young children, and is evidently connected with impaired nutrition. It may also be the result of inflammation of the mucous membrane of the mouth, or it may depend on the development of cryptogamic vegetation on the mucous membrane. The symptoms are numerous small white spots on the mucous membrane of the mouth, the inner surface of the lips, and especially near the angles of the mouth, the inside of the cheeks, the tongue, and sometimes on the gums. The spots are generally of a circular form, about the size of a pin's head, and are firmly adherent. Sometimes the spots coalesce, and the mouth may be extensively coated with a false membrane, a condition sometimes called Aphtha (q. v.).

Thrush, in veterinary surgery, is an affection of the horse's 'frog,' appearing as a severe and acute inflammation, which usually proceeds to ulceration, and which is accompanied by a fœtid discharge. It is most frequently seen in horses of unsound constitution, and especially appears in stables where the drainage is deficient, and uncleanliness prevails. The best application for T. is *mineral tar*. Calomel-dressing is to be substituted for the tar in severe and intractable cases, and ulcerated and loose parts of the frog are to be carefully removed.

Thucyd'ides, the greatest of the Greek historians, was born at or near Athens, about 471 B.C. He belonged to a noble and wealthy family of Thracian origin. From his own pages we gather that he had some hereditary property in gold mines at Scapti-Hyle in Thrace, and that he saw service as a divisional commander in the war of which he became the historian. He is said to have been instructed by Antiphon in oratory, and by Anaxagoras in philosophy. He was one of the few sufferers who recovered from the plague at Athens in 430 B.C. In 424 he held a naval command in the Peloponnesian War, but the expedition under his charge was unsuccessful, and he was forced to go into exile for twenty years (423-403). This long interval he passed in travelling, collecting materials for and writing his history. Soon after his return, about 401, he met his death, probably by assassination, either at Athens or at Scapti-Hyle. T. wrote one great work, *The History of the Peloponnesian War*. It is divided, though not by the author himself, into eight books. There are doubts as to the genuineness of the last of these. In the first book, after a rapid review of the previous history of Greece (chaps. 1-21), he sets forth the alleged causes of the war, and narrates the preliminary negotiations, with digressions on the rise of Athens, the treason of Pausanias, and the exile of Themistocles. The remaining seven books are occupied with the annals of the war. Their form is that of a yearly chronicle of events, and each year is divided into two parts, summer and winter. The history terminates six years before the final conclusion of peace. The merits of T. as a historian are very high. He was an acute and experienced observer, and an accurate and unprejudiced reporter. His work is written in accordance with the principles of ancient literary art. He does not turn aside to notice any collateral subject, but relates with plain directness the events that directly concern his purpose. His style has the severe simplicity of an antique statue. His account of the plague at Athens, and of the disastrous expedition against Syracuse,

are justly regarded as masterpieces of historic description. The speeches with which he has interspersed his relation form in many respects a striking contrast to the rest of the work. 'They do not arise from the narrative, but are fitted into it.' They are reviews of the situation, maxims of polity, encouragements and exhortations put into the mouths of the leaders of the opposing parties. To a great extent they must have been the work of the historian himself. They are often involved in construction and difficult to follow, the thought seems too weighty for the words that attempt to express it, yet they contain many passages of the very highest merit. The noble oration which Pericles is represented as delivering over the ashes of the Athenian soldiers, is surpassed by no passage in the greatest of the Attic orators. The best editions of T. are by Bekker (3 vols. Berl. 1821), Poppo (10 vols. Leip. 1821-38), Arnold (3 vols. Oxf. 1830-35); the best translations—French, by Zerost and M. Betant (Par. 1853 and 1863), English by Hobbes (Lond. 1628), and Bloomfield (1829), German by Klein (Munich 1826). For a popular account see also the volume by the Rev. W. Lucas Collins in Blackwood's *Ancient Classics for English Readers* (1878).

Thug (*thag*, a Sanskrit word for 'cheat,' 'knave'), a term specially applied to a peculiar class of robbers and assassins, who rendered all the roads in Central and Northern India unsafe up to the beginning of this century. They sallied forth in small gangs, and having gained the confidence of fellow-travellers, took a favourable opportunity of strangling them by a peculiar twist of their turbans or kerchiefs. They had a special thieves' language of their own. The more correct appellation is *phansi-kar*, 'stranglers,' from *phansa* = 'a noose.' They are said to have sprung up under the Mogul dynasty; Akbar executed 500 at Etawah. In the same neighbourhood, in 1810, 30 dead bodies of their victims were taken out of the wells in one year. In 1830 a special department for the suppression of Thugism was organised by the British Government under Lord H. Bentinck, and put under the charge of Colonel Sleeman. The energetic measures adopted were thoroughly successful, and it is believed that this class of murderers is now extinct, though they have left successors in secret poisoners. See Colonel Meadows Taylor's *Confessions of a T.* (Lond. 1840).

Thuja. See ARBOR VITÆ.

Thu'le, the name given in classical writings to an island of the Atlantic—the farthest N. portion of the land-surface of the globe. Pliny (ii. 77) tells how Pytheas, a Greek navigator of Alexander the Great's time, discovered it by a six days' voyage N. from Orkney. Hence it is usually identified with Iceland, or some part of Scandinavia. Ptolemy, however, identified it with the *Mainland* of Shetland, and is supported in modern times by Kiepert. Tacitus (Agri 10) describes it as having been sighted by a fleet which subdued Orkney, so that he probably meant Shetland. In later Roman times *ultima T.* came to be a more or less indefinite term for the 'far North' The probable root of the word occurs both in the Teutonic and classical languages, as the Gothic Tiel and the Greek *telos* ('end').

Thumb'ikins or **Thumb'screw**, an instrument of torture for violently compressing the thumbs, employed by the Inquisition (q. v.), and also much used in Scotland during the 17th c. It consists essentially of two metal bars, which are made to approach each other by means of a screw.

Thun, a picturesque Swiss town in the canton of Bern, beautifully situated on the Aar, ¾ miles below its efflux from the Lake of T., 18 miles from Interlaken, and 32 miles S.S.E. of Bern by rail. Its principal street is curious—in front of the houses projects a row of magazines and cellars 10 feet in height, the flat roofs of which afford a pavement for foot passengers flanked with the shops. From the bridge a covered way of 218 steps leads to the church, erected in 1738; near the churchyard is the square tower of the old castle of Zähringen-Kyburg, within which is the Amts-Schloss, or residence of the bailiffs, erected in 1429. T. contains the military school of the Swiss confederation, and is the chief seat of the trade of the Oberland. Pop. (1870) 4623.—The **Lake of T.** extends S.E. for 10½ miles with a breadth of 2 miles, and is 1837 feet above the sea-level. Its greatest depth is 1844 feet. Its banks in the S. are fringed with picturesque villas and gardens; in the northern part by bold, rocky cliffs. To the S. stand the Niesen (7765 feet in height) and the Stockhorn (7195 feet high). See *Thun und Thuner See* (Zür. 1878).

Thun'der. See LIGHTNING.

Thur (*thar*), the great Indian desert which intervenes between the left bank of the river Indus and the hills of Rajputana, has a total area of about 68,700 sq. miles. It consists of a succession of sandy ridges, in appearance like the waves of a sea, running N.E. and S.W., and highest towards the E. It is thought that much of this tract was once fertilised by the Indus or its branches. No rain falls on the T., and it is now almost uninhabited. The *district* of T. and Parkur, province of Scinde, Bombay Presidency, has an area of 12,729 sq. miles, and a pop. (1872) of 180,761. The only town is Umarkote (q. v.).

Thur'gau (Fr. *Thurgovie*), a Swiss canton, stretching in the W. and E. along the Lake of Constance and the Rhine, comprises the fertile valley of the Thur, and the smaller vales which diverge from it. Area, 379 sq. miles; pop. (1877) 95,390, of whom 69,231 are Protestants, and 23,454 Roman Catholics. T. is only mountainous in the S., where rises the Hörnli, 3605 feet high. One of the richest of the Swiss cantons, it has 35,082 hectolitres under corn, and 22,000 in meadow, and produces much fruit and wine. The number of cattle (1874) was 34,719, of horses 3157, of sheep 2697, of goats 6571, of swine 6660, of bee-hives 7091. There are important fisheries in Lake Constance and the Rhine, yielding 150,000 trout annually. Frauenfeld is the capital, and the chief industrial establishments are cotton-mills, and dye and print works. The Rhine valley railway is continued along Lake Constance, and is joined at Romanshorn by the line from Zürich, which traverses T. from E. to W., crossing the Limmat by an iron bridge, and passing under the Käferberg by a tunnel 1020 yards long. See Häberlin, *Der Kanton T.* (Frauenfeld 1877).

Thur'ifer. See INCENSE.

Thurin'gia (Ger. *Thuringen*), the name given to that part of Central Germany lying between the Thuringer-Wald and the Harz Mountains, and including parts of the Prussian province of Saxony and the Saxon duchies. It is derived from the Thuringii, who were in possession of the country in the 5th c., and who were probably descended from the Hermunduri. The name has only a lax geographical meaning.—**Thuringer-Wald**, a mountain-range, extends along the right bank of the Werra from the influx of the Horsel for about 60 miles, and then joins the Frankener-Wald in N. Bavaria. It is covered with pine forests, and consists mainly of granite, porphyry, and slate, containing rich veins of iron ore. The highest points are Schneekopf (3400 feet), Gross-Beerberg (3435), Inselberg (3223), and Finsterberg (3209).

Thurles, a market town of Tipperary, Ireland, on the Suir, 86¼ miles S.W. of Dublin by rail, contains a fine Catholic cathedral, some religious houses, and St. Patrick's College (1836). Chiefly agricultural, it has some manufactures of shoes, wool, and shirts. Pop. (1871) 5008, of whom 1873 were Catholics. At T., in the 10th c., the Irish defeated the Danes.

Thur'low, Edward, Lord, second son of the Rev. Thomas T., was born in 1735 at Little Ashfield, Suffolk, educated at Caius College, Cambridge, and called to the bar in 1758. His imposing manner and sonorous voice made a favourable impression, and his appearance as junior counsel in the great Douglas case established his reputation. In 1771 he became Solicitor-General, and zealously supported the policy of the Government towards its American colonies. In 1778 he was raised to the woolsack, but was soon discovered to be an impracticable and troublesome member of the administration. When Pitt became Premier in 1783, T. ostensibly supported him for a time, but at last his enmity could no longer conceal itself, and he began to openly oppose the measures of the ministry. In 1792 Pitt demanded and obtained his removal from office. His public career thus suddenly came to an end, and the remainder of his life was spent in obscurity. He died at Brighton, September 12. 1806. 'No man,' said Fox, 'was ever so wise as Lord T. looked.' T.'s personal habits were far from irreproachable; and on the memorable occasion when he wound up a defence of the king with 'When I forget my sovereign, may my God forget me!' Wilkes is reported to have replied, 'Forget you! He'll see you d——d first!' Nothing that is known of this celebrated lawyer justifies the distinction to which he attained. See Campbell's *Lives of the Lord Chancellors, &c.* (8 vols. 1846-47).

Thur'mayr. See AVENTINUS.

Thurs'day (Scan. *Thorsdag*; Ger. *Donnerstag*), the fifth day of the week, named after the god Thor (q. v.). Among the Romans the same day was dedicated to Jupiter, and called *Dies Jovis* (Fr. *Jeudi*).

Thur'so ('Thor's town'), the most northerly town of Scotland, in Caithness, 21 miles N.W. of Wick. It is the terminus of a branch line of the Sutherland and Caithness railway, and is magnificently situated on a spacious bay of its own name (also called Scrabster Roads), which affords excellent anchorage, and is confined on either side by the bold rocky masses of Holborn Head and Dunnet Head, rising to a height of 300 feet. Between the two promontories T. looks out over the wild Pentland Firth to the grand cliff scenery of Hoy and others of the more southerly Orkneys. The River T., which is 25 miles long, and is here crossed by a stone bridge, affords good salmon-fishing. The harbour is obstructed by a bar, but has a good pier and custom-house. T. is an important fishing centre, exports fish, Caithness flagstone, cattle, sheep, &c., and has some linen, woollen, leather, and straw-plait industries. A little to the E. stands T. Castle, the seat of Sir G. Sinclair, Bart., and further along the shore Harold's Cross, erected to the memory of Harold, Earl of Caithness, who fell here in 1190. Pop. (1871) 3604. T. was the home of Robert Dick, the Caithness geologist, and the subject of Smiles' charming memoir, published in 1878.

Thwarts are the transverse planks of a boat which keep the sides apart, and on which the rowers sit.

Thy'lacine (*Thylacinus cynocephalus*), a species of rapacious or carnivorous *Marsupialia* (q. v.) inhabiting Tasmania, where it is named the 'native hyæna' by the colonists. The head is large and prominent, and the back is transversely striped with bands of dark hue. T. attains the size of a large dog, and as it is destructive to sheep and other animals, a constant war of extermination is carried on against it.

Thylaco'leo, a remarkable genus of extinct *Marsupialia* (q. v.), the fossil remains of which occur in the Recent or Tertiary and Post-Tertiary deposits of Australia and Tasmania. Professor Flowers regards T. as a 'highly-modified and aberrant form of the type of marsupials now represented by the *Macropodidæ* (Kangaroos) and *Phalangistidæ* (Phalangers, q. v.), though not belonging to either of these families as now restricted.' A characteristic of T. is the presence in each jaw of one large, compressed, and sharp-edged premolar tooth. The canines are small.

Thyme (Gr. *Thymus*), a genus of *Labiatæ*, comprising about 40 species of much-branched, very aromatic small shrubs, with small entire leaves and whorled flowers arranged in spikes. The plants are often hoary. The species are natives of temperate regions of the Old World, particularly of the Mediterranean region. Garden T. (T. *vulgaris*), of which the young leaves and tops are used either green or dried in soups, stuffings, stews, or sauces, is a S. Europe plant. The oil of Origanum of commerce is obtained from it. The familiar wild T. of dry banks, pastures, and hill-sides grows from Greenland eastward to the Himalaya. A variety, called Lemon T. (T. *citridorus* of Persoon), is grown in gardens for its grateful scent and for seasoning.

Thymelea'ceæ, a natural order of gamopetalous dicotyledonous shrubs, small trees, or wiry herbs, with tenacious inner-bark and acrid juice. T. contains 40 genera and about 300 species, dispersed through temperate and tropical regions, predominating in S. Africa, and many occurring in Australia. The best-known genus is *Daphne* (q. v.). In N. America the tough branches of *Dirca palustris* or 'Leather-wood' are used for cordage and basket-making. Under this order is generally classed *Aquilaria agallocha*, which yields a great portion of the famous aloes-wood or eagle-wood used in incense, and to make ornaments and rosary beads. *Pimelia*, an extensive Australian and New Zealand genus, extremely variable in foliage, includes several species grown as ornamental greenhouse plants, and some of the species supply a cloth and string from their bark. The fruit of *P. arenaria* is eaten. *Struthiola*, a large genus of pretty plants with white flowers deliciously scented in the evening, and *Gnidia*, with yellow, pink, blue, or white flowers, and some large and handsome *Passerina*, are greenhouse plants in Europe introduced from Africa. See LACE-BARK TREE.

Thy'mus Gland, a structure occurring in the neck, and usually considered one of the so-called *ductless glands*, of which the Spleen (q. v.) is the best-known example. The T. G. is at best a temporary organ in human existence. It attains the maximum of its growth about the end of the second year of life, and thereafter dwindles, until at the period of Puberty (q. v.) it has well-nigh disappeared. It consists at its period of full development of two lobes, united in the median line, and situated partly in the neck and partly in the space known as the *mediastinum*. The T. G. is covered by the breastbone and by the origins of the *sterno-hyoid* and *sterno-thyroid* muscles. Its colour is a pinkish-grey, and its consistence is soft. Externally it presents a lobulated appearance. Its length is about 2 inches, and its thickness three or four lines. Its weight at birth is about half an ounce. Each lobe of the T. G. is composed of *lobules*, united by delicate areolar tissue, the lobules varying in size from a pin's head to a small pea. In the centre of each lobule is a small cavity, and these cavities open into the larger cavity of the lobe, named the *reservoir of the thymus*. The latter cavity has a vascular lining membrane, and usually contains a milky fluid resembling *chyle*. This fluid contains corpuscles, undistinguishable from chyle-corpuscles, and attaining a diameter of the one-thousandth part of an inch. The T. G. derives its blood from the internal mammary and superior and inferior thyroid arteries, whilst its nerves are obtained from the pneumo-gastric and sympathetic trunks. Chemically examined, the T. G. is found to consist of albumen and fibrine, along with gelatine, and alkaline and earthy phosphates, with chloride of potassium. Water to the extent of 80 per cent. enters into the composition of this gland, whose functions are as yet undetermined.

Thyroid' Gland, one of the *ductless glands*, and therefore in the same category as the spleen, thymus gland, and supra-renal capsules. The T. G. lies at the upper part of the *trachea* or windpipe. It consists of two lobes or halves, placed one on each side of the windpipe, and united by a narrow connecting band, the *isthmus of the thyroid*. Its colour is a brownish red, and its weight varies, the maximum being about 2 ounces. In females it is larger than in males, and is said to increase in size during menstruation. When enlarged, the T. G. gives rise to the disease known as *Goitre* or *Bronchocele*. Each lobe of this gland attains a length of two inches, and three-fourths of an inch in breadth. Occasionally a third lobe, called the *pyramid*, is found to arise from the upper part of the isthmus on the left side, or from the left lobe of the gland itself. In minute structure the T. G. consists of small closed sacs or vesicles surrounded by a dense network of blood-vessels. The vesicles contain a yellowish fluid, in which numerous *corpuscles* or nucleated cells are found. The arteries of the T. G. are named the *superior and inferior thyroid*. They are large and unite frequently in the course of their distribution. The nerves of the T. G. are obtained from the *pneumogastric trunks*, and also from the *sympathetic system*. The functions of this gland, like those of the Thymus Gland (q. v.), are still unknown.

Thyr'sus, in botany, is the name for an Inflorescence (q. v.) where *cymes* of flowers are arranged in a narrow pyramidal panicle; or where a much-branched panicle is pyramidal in shape. Common examples are the lilac and the horse-chestnut.

Thysanu'ra, according to Latreille, an order of lower insects distinguished by the want of metamorphosis, the absence of wings, and the sharpness of its bite. Most authorities now regard the T. as a form transitional in nature between *Insects* and *Myriapoda*. The best-known genus are the *Lepismatidæ*, including the sugar-mites and bristle-tails, and the *Poduridæ* or spring-tails. The possession of terminal bristles, by the sudden recoil of which these insects leap, is the most marked characteristic.

Tia'ra is the name of the Pope's triple crown, which is the symbol of his temporal power as the keys are of his spiritual jurisdiction. Originally a round cap, there was afterwards affixed to it a crown or border of crosses to indicate an acquisition of regal power. A second crown was added by Boniface VIII. in 1299, and a third by Urban V. in 1362.

Ti'ber (Lat. *Tiberis*), the most famous of Italian rivers, rises at the base of Mount Aquitone, a spur of the Apennines, province of Arezzo, at a height of 1600 feet above the sea. In its sinuous southerly course it passes Perugia, Todi, Orvieto, and Rome, and receives the Chiasca, Nera (*Nar*), and Teverone or Anieni (*Anio*) from the left, and from the right the Chiana and

Paglia. In the Campagna it swerves to the S.S.W., and enters the Mediterranean 27 miles below Rome by two branches, enclosing the Isola Sacra. Its length is 220 miles, its drainage area 6500 sq. miles. Of its two mouths, the more northerly, the Fiumicino, is the channel of a considerable import trade in wine, corn, charcoal, &c. But the T. is only navigable for vessels of 140 tons to Rome, at which point it is 300 feet broad, and from 12 to 18 deep. Its mean delivery is about 400 cubic yards per second, greater than that of the Thames and Severn put together; its smallest volume is 215 cubic yards. Rozet calculated that the sediment deposited at its outlet had varied little for centuries, and was enough to extend the coast at the rate of 13 feet yearly. It was possible under the Empire to land an obelisk of 400 tons brought from Egypt, at a point only 3 miles below Rome. But the estuary which formed the ancient harbour became silted to such an extent that it was found necessary to cut an emissary from a point considerably above Ostia, and this ship-canal is the modern Fiumicino. A project set on foot by Garibaldi to divert the T. into a new channel from above Rome, to save that city from inundations and improve the climate and the Campagna, has been abandoned, but there are still various schemes advanced for the canalisation or embankment of the river. Against the feasibility of these designs are urged the amount of rainfall and its periodicity, the concurrence of overflow in the tributary basins, the permeability of the soil, the shortness of the river's lower course, with its almost imperceptible slope from Rome of one inch to the mile, and the constant level of a tideless sea. The last great inundation was that of 1870, when the river rose 12·15 feet above the pavement of the Ripetta, and flooded the whole N.W. quarter of Rome, including the Corso. Such inundations, by checking the sewers, seriously interfere as a rule with the sanitary state of the city, but in this case no evil result followed. A railway from Rome to its port of Fiumicino was opened in February 1878. See *Studi sulla Geographia Naturale e Civile dell' Italia* (*Soc. Geo. Italiana*); W. Davies' *Pilgrimage of the T., from its Mouth to its Source* (Lond. 1873); and S. A. Smith's *T. and its Tributaries, their Natural History and Classical Associations* (Lond. 1877).

Tibe'rias (mod. *Taberije*), historically a very important town of Galilee (q. v.) on the S.W. shore of the Sea of Genesareth, which took from it the name of the Sea of T., was founded by Herod Agrippa in honour of the Emperor Tiberius (q. v.). For many centuries after the fall of the Roman Empire in Syria it was a seat of Jewish learning. After the First Crusade it was erected into a principality, but on the defeat of the Christians by Saladin in the neighbouring plains, July 4, 1187, was reduced to ruins. On New Year's Day, 1837, it was again destroyed by an earthquake, and has now barely 2000 inhabitants, of whom three-fourths are Jews.

Tibe'rius (Claudius Nero Cæsar), the second Roman emperor, was born November 16, 42 B.C. He was the son of Tiberius Claudius Nero and Livia Drusilla, who became the wife of Octavianus Cæsar in 38 B.C. T. and his brother Drusus were now brought up in the household of their stepfather, who from the year 27 B.C. was the Emperor Augustus. They were early initiated into public affairs, and in 16–15 B.C., at the head of a Roman army, subdued the Rhaeti and Vindelici. T. now returned to Rome to celebrate his first triumph, and in 13 B.C. was appointed consul together with P. Quintilius Varus. Meanwhile, Drusus carried on the war in Germany with great success, but died in 9 B.C., in consequence of a fall from his horse. T. hastened to Germany, and, after having carried his brother's body to Rome, returned and prosecuted the war with great vigour. In 7 B.C., having led his army across the Rhine into the country already half conquered by Drusus, he returned to Rome, becoming consul for the second time, and celebrating his triumph in the same year. In 12 B.C. he had been compelled by Augustus to divorce his wife Vipsania Agrippina, and become the third husband of his infamous daughter Julia; but, disgusted by her profligacy, and by Augustus having appointed as his successors Caius and Lucius Cæsar, her two sons by her second husband, Marcus Vipsanius Agrippa, he voluntarily retired to Rhodes in 6 B.C., where he passed seven years in seclusion. He returned to Rome 2 A.D., in which year Lucius Cæsar died at Massilia, on his way to Spain, while his brother Caius died a year and a half later in the East from a wound which he had received in the Parthian war. T. was accordingly adopted by Augustus as his successor in 4 A.D. In the same year he led an army into Germany, marched to the Elbe, and defeated the Sigambri, Bructeri, and Cherusci. The suppression of a revolt in Pannonia and Dalmatia procured for him the honour of a third triumph. He was now sent once more against the Germans, who, under their great chief Arminius, had cut off Quintilius Varus, with three legions. Accompanied by the young Germanicus, he crossed the Rhine, and during the years A.D. 11 and 12 traversed the countries E. of that river. On the death of Augustus, in 14, T. became emperor. He was in his fifty-fifth year, and, though beloved by none, he was much respected for the dignity of his demeanour and the reputed severity of his virtue. For some years he affected to take no active part in public affairs, while he gradually destroyed the last remnants of the ancient republic, abolishing the *Comitia*, and transferring the election of public officers to the subservient senate. Augustus had employed the *Lex Julia Majestatis* to punish the authors of libels against his person, and T., following his example, established the *Judicia Majestatis*, for the trial of persons suspected of having, in word or deed, impugned the majesty of the emperor. The number of *delatores*, or public denouncers, daily increased, while every citizen moved in an air of anxiety and suspicion. After the death of Germanicus in 19, not without suspicion of poisoning, T. strove less to conceal his hidden vices, while the servility of the senate, and the irritation of pasquinades and continual discoveries of plots, deepened the gloom of his suspicion. In his 67th year he retired to the island of Capreæ to enjoy seclusion, leaving to Ælius Sejanus (q. v.), commander of the Prætorian guards, the direction of public affairs. Blinded by the misrepresentations of Sejanus, he agreed to every measure which the latter felt to be conducive to his own ambition, and a long and uniform series of cruelties followed. Awakened at last to the ambitious schemes of his favourite, T. ordered the senate to condemn Sejanus, and the latter, with his family and friends, was put to death in 31. Some time after this, T. took up his residence at Misenum, where, as at Capreæ, he plunged himself into the most disgusting debauchery. On the 16th of March, A.D. 37, he fell into a lethargy, and being believed to be dead, Caligula was proclaimed emperor. T., however, recovered, but he was suffocated in his bed by Macro, to save himself and the young emperor. The elaborate picture of the emperor given in the first six books of the Annals of Tacitus, can hardly be considered a fair representation of his character. The historian, as an admirer of the old republic, had a strong bias which impelled him to take the worst view, and he has himself confessed that he drew his accounts from poisoned sources. The history of T., he tells us, 'was falsified, while he reigned, through terror, and written after his death with the irritation of a recent hatred.' That T. was a brave and skilful soldier and a careful financier cannot be doubted; while, however, unpopular at Rome, he was regarded by the provincials as a wise and beneficent ruler. Perhaps a taint of the insanity which was characteristic of the Claudian house, and a vein of superstition and fatalism, go far to explain many of the acts of 'atrocious villany and revolting depravity' which disgraced his later years. See Freytag, *T. und Tacitus* (Berl. 1870), T. Stahr, *T.* (2d ed. Berl. 1873), and E. S. Beesley's *Cataline, Clodius, and T.* (Lond. 1878).

Tibet' or **Thibet'** (native name *Bod* and *Bodyul*, Ind. *Bhot* and *Bhotiya*), the name applied by Europeans to the country of Central Asia, separated on the S. from India by the Himalaya, and bounded N. by Mongolia, E. by China proper, and W. by Turkestan, between 28–35½° N. lat., and 79–95° E. long. Area 999,220 sq. miles; pop. estimated at 4,000,000.

Physical Features.—T. is divided into four great provinces—Kam, in the E., bordering on Szechuen in China; Ari, the mountainous region W. of the Marjam-la Pass, including Ladak; U, and Tsang forming Great T., extending from the Mariam-la down the basin of the Brahmaputra. The lower part of T. consists of an elevated, undulating valley, with a N.W. to S.E. slope, and an average elevation of 15,000 feet, between the southern and central of the three great parallel chains of the Himalaya (q. v.). The most northern of the three is divided into two sections, the western or Karakorum Range separating the valley of the Indus from that of the Yarkand River and the other streams belonging to the inland system of Lob-Nor, and

the eastern, the Ninjinthangla or Nyenchhen-tang-la Mountains, extending E. and N.E. from the peak Kailas or Gangri (22,000 feet), forming the northern watershed of the Brahmaputra, and reaching in its highest point to 25,000 feet. The southern watershed of the Brahmaputra is the Central Chain, diverging from the Mariam-la Pass near the Gangri peak, which divides the Sutlej from the Brahmaputra, and extending parallel to the northern chain. On its southern slopes are the sources of the Kali, Karnali, Narayani, Arun, and Subanshiri, which force themselves through the southern chain of the Himalaya and reach the plains of India to join the Ganges or Brahmaputra, and it is crossed by the passes of Lagulung-la (16,000 feet), Taku-la, No-la (16,623 feet), and Photu-la (15,080 feet). The Southern Himalaya, which separates T. from Nepaul, Sikkim, and Bhutan, is a stupendous ridge throwing up the highest peaks on the surface of the globe, and is intersected by deep river gorges and narrow passes, of which the principal are, in Nepaul, Taklakhar and Kirong, the latter the highroad from Khatmandu to T., in Sikkim, Donkia, Kongra Lama, Dangola, and Jeylub, and in the Chumbi valley, Pari-jong, the pass by which Bogle and Manning entered T. Numerous freshwater lakes occur on the declivities between the chains, in the region of the Sutlej, Rakas-Tal, and Mansarowar (*Mapang*), (15,472 feet). In the E. part of the central range is Lake Palti, Peiti, or Yamdok-chu (13,590 feet). In Cashmerian T. are numerous salt lakes, of which the largest are Pang-Kong and Tsomoriri, near the English frontier (14,900 feet). From the northern region to the Kuen-Lun Mountains extends a region called by the natives Horsok, consisting of a broad series of elevated and still unexplored steppes, sparsely covered with grass, in which groups of parallel chains raise themselves upwards of 3000 feet. Numerous lakes occur, many of them salt, of which the chief are in the E., Namcho or Tengri-Nor (15,200 feet), and in the W., Ike Namur Nor and Bakha Namur Nor.

Climate, Productions, &c.—The mean annual temperature in T. at an altitude of 12,000 feet is 41-43° F., and the lowest 4° F. The remarkable aridity of the atmosphere modifies the extreme cold consequent on the great elevation. The snow-line, which is on the S. slope of the Himalaya 14,000 feet, is 16,000 on the northern declivities, and in the valleys of T. corn is sown at a height of even 16,500 feet, while roses grow up to 13,000 feet. Barley and leguminous plants are sown, and rye and wheat in the valley of the Brahmaputra up to a height of 12,000 feet; these crops, however, do not ripen until September. From the want of irrigation, agriculture is only possible in the valleys; in the higher grounds the pastures are frequented in summer by wandering tribes. There is an utter destitution of forest in T.; poplars and willows are the principal timber, and the only fuel is the dung of cattle. The principal domestic animals are the yak, a small kind of horse, goats with long coats of a fine wool known as *pashne*, sheep and dogs, of which great numbers are kept. The principal wild animals are the muskdeer, the kyang, the yak, a very large mountain sheep (*Ovis argali*), the Pseudovis nahoor, another sheep as large as a common deer, bears of a small kind, and a species of leopard (*Felis macroscelides*). T. has a large trade with Mongolia and China, and with Nepaul and Bhutan by the Himalaya passes. The merchants come in December and leave in March before the rivers are flooded. The chief articles of export are silver, gold, salt, borax, woollen stuffs, furs, drugs, musk, and wool; and the chief articles imported are, from China, silks, carpets, and hardware; from Mongolia, leather saddlery, sheep, and horses; from Bhutan and Sikkim, rice and tobacco; from Nepaul, silk, indigo, coral, sugar, spices, and Indian manufactures; and from Ladak and Cashmere, saffron and Indian commodities. Lassa and Shigatze are the centres of trade, and the principal marts outside of T. are Dewangiri and Udelgiri in Assam, Darjiling for the Chumbi valley trade, Patna for that passing through Nepaul, and Cashmere for the long route by the Mariam-la pass.

Inhabitants, Religion, &c.—The greater number of the inhabitants of T. are of Mongolian origin. On the northern steppes are two distinct nomadic races, the Hor of Turkish origin and the Sok of Mongolian, which, however, are both styled Kháchhén (Mohammedans) by the Tibetans. Caste divisions do not exist in T. Polygamy is common among the more wealthy, and among the people, polyandry, owing to the general poverty. The tone of morality is consequently low, while the people are sunk in ignorance and superstition. The religion is Buddhism (q. v.), though there still lingers in Kam an old religion called *Bon* or *Pon*, which seems to have been a worship of the powers of nature. The three principal incarnations are the Dalai Lama, the Buddhist pope, the Teshu Lama, and the Taranath Lama. Next to these are the abbots of monasteries, and under them the priests (see LAMAISM), who are all subjected to celibacy, and divided into several classes. On an average every thirteenth, in some places every seventh, man is a monk. Religious services are conducted with a gorgeous and imposing ritual. Characteristic of T. are the mechanical prayer-mills, found everywhere, and the prayer-flags, each inscribed with the mystic paternoster, *Om Mani padme hum* ('Ah, the jewel is in the lotus').

Language and Literature.—The language of T. is one of the monosyllabic speeches of Eastern Asia, and has preserved the same written form for upwards of 1200 years, while the style and the oral speech have undergone considerable change. In 632 A.D., the Indian Devanagari alphabet was introduced, and the work of translating from the Sanscrit the sacred Buddhist books begun by order of King Srongtsan Gampo. These, with a few original works, form two large collections,—the *Kanjoor*, of 100 vols. in seven divisions, and the *Tanjoor*, in 225 vols. The language has thirty consonants, no diphthongs. In writing, each syllable is separated by a point. Inflexion is supplied by connecting affixes or suffixes, but in the verbs, changes in the roots are frequent. The verb is impersonal, has no distinguishing forms for active and passive, and generally stands as the last word in the sentence. Grammars have been published by Schröter (Serampore 1826), Csoma (Calcutta 1834), J. F. Schmidt (St. Petersb. 1839-41), Foucaux (Par. 1858); the best, however, is the *Short Practical Grammar of the T. Language* (Kyelang in Lahol 1865), by H. A. Jäschke, who has also published a *Tibetan-English Dictionary, romanised* (*ib.* 1866), and a great *Stellenwörterbuch der Tibetsprache* (Gnadau 1871-75).

History.—The traditional history of T. begins in the first century before Christ. Two hundred years later a great part of the country was subdued by China. Buddhism was introduced by King Srongtsan Gampo, who made Lhasa his capital. In 1640, after many struggles, the crozier proved stronger than the sword, and the Dalai Lama became temporal sovereign of T. At the beginning of the 18th c., in consequence of a prime-minister having concealed the death of the Dalai Lama for some years, the Chinese interfered, and from that time T. became a Chinese province. The Chinese mandarins assume a superintendence over the election of the Dalai Lama and the government of the country. The last election took place in 1875, when a child from western T. was elected. The Chinese government in the past has invariably put every obstacle in the way of the opening up of the country, but by the Chefoo Convention in 1877 has permitted the residence of an English embassy in Lhasa. The famous Lama survey of T. was begun in 1708, and completed in 1718, still the basis of our geographical knowledge of T., though it is now being superseded by the labours of Colonel Montgomerie's pundits. The first Englishman to travel in T. was George Bogle, who was despatched by Warren Hastings in 1744, but was prevented by the Chinese from proceeding to Lhasa, and obliged to return in June 1775. In 1811 Thomas Manning was successful in reaching Lhasa, and he is still the only Englishman who has ever seen 'the holy city.' The only Europeans who have visited it since his time are the French missionaries Huc and Gabet. During the last ten years trained native explorers have been despatched by Colonel Montgomerie, and have added much to our knowledge of T. See Colonel Montgomerie's *Reports of Trans-Himalayan Explorations*, published in the *Journal of the Royal Geographical Society*; E. Schlagintweit, *Buddhism in T.* (Leips. 1863); Desgodins, *La Mission du T.* (Verdun and Par. 1872); Brian Hodgson, *Essays on the Language, Literature, and Religion of Nepaul and T.* (Strasb. 1874); W. T. Heeley in the *Calcutta Review* for July 1874; C. R. Markham, *Narratives of the Mission of George Bogle to T., and of the Journey of Thomas Manning to Lhasa* (Lond. 1876); and Ganzenmüller, *T.* (Stuttg. 1878).

Tibul'lus, Al'bius (his prænomen is unknown), the most graceful and finished of Roman elegists, was born at Pedum, between Præneste and Tibur, *circa* 700 A.U.C. His father seems to have died while he was still very young. Allusion to his father is nowhere made in the works that bear his name, save

in a passage in the *Book of Lygdamus* (iii. 5, 17-18), a work which the majority of critics, since the promulgation of the ingenious theory of J. H. Voss in 1786, have agreed to consider spurious. T., however, speaks of his mother and sister with feelings of tenderest regard (El. i. 3, 4-7). He inherited lands, wealth, and position, but was deprived of his patrimonial possessions in the confiscation of property consequent on Cæsar's death. Some portion thereof had, however, either been left to him, or restored through some friend's intervention. While most of the poets of the brilliant Augustan period—the golden age of Roman literature—enjoyed the patronage of the cultured and courtly Mæcenas, T. attached himself to the coterie of Marcus Valerius Messala Corvinus, whose friendship and favour he enjoyed through life. In 723, A.U.C., he went in that general's suite as aide-de-camp in a descent on the rebel tribes of Aquitaine, and was present in the battle of Atax (mod. *Aude*: see Book i. El. vii. *passim*). In 724 he went with Messala on his Asiatic expedition, but a serious illness prevented his proceeding further than Corcyra (*Corfu*). On his recovery he returned to Rome, and soon after sought his country seat at Pedum, there to spend for the most part the remainder of his days in the pursuits of literature and love. Beyond what has been stated, the life of T., uneventful and comparatively aimless, must be gleaned solely from his elegies. The names or pseudonyms of two ladies at least—Delia and Nemesis—are in his verse destined to imperishable fame. As a man T. possessed intense earnestness, a genial and kindly spirit, and withal a singular disposition to forgiveness. All ancient writers speak of him with unqualified admiration and praise. Some modern *soi-disant* authorities, on the other hand, have decried his sentimentalism and tender melancholy as un-antique. It may be safely assumed that they do not understand him. T. throughout evinces a simplicity, a terseness, a tenderness, and a naturalness unapproached in Roman elegy—the rich and sensuous verses of Ovid and the nervous and brilliant passion-strains of Propertius not excepted. The social virtues of T. were great. His intense love of primitive life and of the simplicity of earlier days will continue to endear him to posterity. In his last illness T. was tended by his mother and sister, with whom his two much-loved mistresses, Delia and Nemesis, met to pay the last tribute at his pyre (A.U.C. 735). The genuineness of the first two Books of Elegies has never been questioned. *The Elegies of Lygdamus* (Book iii.) are, in the opinion of most critics, by a later hand. The fourth Book contains a long and dreary panegyric to Messala, one unquestioned elegy (xiii.) by T. at his best, and a few short poems of exquisite grace and finish by a certain Sulpicia. The *editio princeps* of T., with Catullus, Propertius, and the *Silvæ* of Statius, was printed at Venice by Vindelin de Spira, 1472. The editions of Broukhusius (Amst. 1708), and of Vulpius (Padua 1738-55) are valuable. Those of Dissen (Götting. 1835), J. H. Voss (Heidelb. 1811), Lachmann (Berl. 1829), Haupt (Leip. 1853, 1861, 1868), Rossbach (Leip. 1855), L. Müller (1870) and Bährens (1878). For a critical estimate of the writings of T., and of the genuineness of the Books, see the works of Voss, Wagner, Ritschl, Teuffel, Bender, Cranstoun; also *Catullus, T., and Propertius*, by Rev. James Davies, M.A., in Blackwood's *Ancient Classics for English Readers* (1876). The most recent English version is that by Cranstoun (Blackwood 1872).

Tic Doloureux, or **Fa'cial Neural'gia**, is a painful affection of the fifth nerve. The supra-orbital branch may be alone affected, the pain being confined to the brow and the top of the head; or the three branches may be generally involved, the pain being diffused over the face and head. The attack may be ushered in by some chilliness and uneasiness, and a twinge of pain which begins just above the eye, on one side, and radiates over the head. The pain is at first paroxysmal, but after a time it becomes continuous, and may be excruciating. T. D. is frequently periodic; is more apt to attack females than males during adult life, and is often connected with menstruation, lactation, mental excitement, and exposure to cold. The general treatment of T. D. consists in the administration of quinine, arsenic, strychnine, iron, phosphorus, and cod-liver oil, but quinine is the most efficacious remedy. The hypodermic injection of morphine is especially valuable, and atropine, daturine, ergotine, and other alkaloids, are also used. Electricity is also useful, and it should be applied to the nerve by sponge-covered electrodes, one pole being placed behind the condyle of the jaw, and the other held for a few minutes over the supra-orbital and infra-orbital foramina, or over the symphysis of the lower jaw.

Tichvin', a town of Russia, government of Novgorod, on the Tichvinka, an affluent of the Sias, 161 miles E. by S. of St. Petersburg. It has four churches, a monastery, and a nunnery, and builds river-boats. Pop. (1870) 5969. The *T. canal-system*, 439 miles in length, stretches from the river Mologa to Lake Ladoga, thus connecting the Volga with the Gulf of Finland. It was completed in 1811.

Tici'no (Ger. *Tessin*), the most southerly of the Swiss cantons, is bounded E. by Grisons, N. by Grisons and Uri, and girt on the W., S., and E. by Italy. Area 1087 sq. miles; pop. (1876) 121,768. Occupied in the N. by the Leopontine Alps, of which the chief height is Mount St. Gothard (q. v.), it falls in the S. into the fertile cultivated plain watered by the T., which procures for the canton the name of the 'Italian Switzerland.' The Alpine slopes are clad with extensive forests, and here the inhabitants are mainly engaged in dairy-farming and cattle-breeding. T. includes almost the whole of Lago Lugano, and the N. part of Lago Maggiore (q. v.). The products of the T. comprise wine, corn, olive-oil, and fine southern fruits. In 1876 the exports amounted to 2,952,502 francs, the imports to 3,386,428, and the public debt, on January 1, 1877, to 7,471,594 francs. The inhabitants, who speak Italian, are mostly Roman Catholics. Bellinzona, Lugano, and Locarno are the chief towns. See Eglis's *Taschenbuch Schweizerischer Geographie, Volkswirtschaft und Kulturgeschichte* (2d ed. Zür. 1878).—**T.**, the river, rises on the S. slope of Mount St. Gothard, flows S. through Lago Maggiore, beyond which it is navigable, and joins the Po 4 miles above Pavia, after a course of 120 miles.

Tick (*Ixodes*), the popular name for various species of mites or *Acarina* of large size which infest dogs, sheep, &c. These mites have a leathery and toughened skin, the maxillæ are three or four-jointed, and the saw-like mandibles have terminal hooks by which the animals adhere to the skin of their host. The legs, numbering eight, are slender and clawed. *I. ricinus* is the common T.; other species are *I. bovis*, *I. unipunctata*, and *I. albipictus*. The dog T. (*I. plumbeus*) is so named from its dull leaden colour. In tropical countries the attacks of the T. are often exceedingly painful. The Tampan (q. v.) is a well-known tropical form of T.; so also is the 'Carapta' of Brazil, which infests dry situations and trees, and is thus enabled to transfer itself to the bodies of passing quadrupeds.

Tickell', Thomas, a minor English poet, was born at Bridekirk, Cumberland, in 1666. After studying at Oxford, where he became Fellow of Queen's College in 1710, he obtained from Addison the office of under-secretary of state in 1717, and about seven years later was appointed secretary to the Lords Justices of Ireland. He died in 1740. T. is mainly remembered by his translation of the first book of *Homer*, his *Elegy on Addison*, and his contributions to the *Spectator*. The first of these has transmitted to modern times a curious question as to its authorship and the circumstances of its birth; for it happened to come out about the same time as Pope's translation, and the suspicious poet averred that it was really the work of Addison, and was issued with a hostile intention towards himself. Dr. Johnson, Goldsmith, and Macaulay agree in high admiration of the *Elegy*, while Steele maintained that it was only prose in rhyme. T.'s poems are collected in vol. xi. of Chalmers' *English Poets*, and an American edition appeared at Boston in 1854.

Ticket-of-Leave is a licence granted to a convict, on account of good conduct, to be at large. It may be granted, under the Act of 1864, to male convicts after three-fourths of the period of sentence has been passed, and to females after two-thirds. It is revocable in case of misconduct, or relapse into crime.

Tick'ing, a strong linen or cotton fabric, striped, and commonly twilled, used to hold feathers, hair, or other material for beds, mattresses, &c.

Tick'nor, George, LL.B., born at Boston, U. S., 1st August 1791, graduated at Dartmouth College (1807), and was called to the bar (1813). A year's experience showed his unfitness for a legal career, and in 1813 he sailed for England, whence, having made acquaintance with Roscoe, Byron, and Sir Humphrey Davy, he proceeded to Göttingen, his residence for eighteen months. During this period he studied, twelve hours a day,

theology, five languages, and natural history; then, having visited Goethe at Weimar, he proceeded to Paris, Geneva, and Rome, being everywhere admitted to the best society. Part of 1818 he spent in Spain, gathering Spanish books and mastering the language; these ends achieved, he travelled back over Paris to England, where he now met Southey, Wordsworth, Scott, and all the coterie of Holland House, and in 1819 returned home to become professor of modern languages at Harvard. Here he continued fifteen years, busied with educational and philanthropic schemes, promoting college reforms, writing for the *North American Review*, and entertaining Lafayette as his guest in 1824. The death of an only son (1834) led T. to resign his professorship and take his family for a three years' tour in Europe, during which he collected further materials for his *History of Spanish Literature* (3 vols. 1849; new ed. 1871), the exhaustive, accurate work on which his reputation is surely founded. Besides short sketches of Lafayette (1825), Daniel Webster (1831), the Buckminsters (1849), Everett (1865), &c., T. published a Life of Prescott (1864), and he was one of the chief founders of the Boston Public Library, to which he presented 2000 volumes. Never illiberal but a Conservative in politics, no abolitionist though hating slavery, the upright, keen-witted, and appreciative friend of most men worthy of his friendship, T. passed his later years in quiet usefulness, and died at Boston, 26th January 1871. See Hillard's *Life, Letters, and Journals of G. T.* (2 vols. Bost. and Lond. 1876), the most interesting biography America has yet produced, containing as it does memorials of Mdme. de Staël, Mdme. Recamier, Chateaubriand, Humboldt, Guizot, Bunsen, Niebuhr, Talleyrand, &c.

Ticondero'ga, a town in New York, U.S., at the outlet of Lake George into Lake Champlain, 80 miles N. of Albany by rail. The outlet is 4 miles long, with a fall of 220 feet, and the water-power supplies many timber, woollen, and cotton mills. Graphite, found in the township, is used in making pencils and crucibles. Pop. (1875) 3401. The promontory was long occupied by the fort of Carillon (1755), so called from the sound of the neighbouring waterfalls. This fort, now a ruin, was Montcalm's headquarters in 1757, was taken by Amherst in 1759, by Ethan Allen in 1775, and by Burgoyne in 1777. See *History of T.* by Rev. Joseph Cook (Keeseville 1858).

Tides are the regular periodic oscillations to which the surface of the sea at any place is subject. The oscillation takes place about twice a day, the periodic time being, on an average, about 12 hours and 26 minutes. Consequently if high tide occurs at noon one day, it will occur next day some fifty minutes later. This is precisely the interval of time which elapses between two successive meridian passages of the moon; and that there must be some connection between the tides and our satellite was early recognised by astronomers. The explanation, however, was lacking until Newton proved them to be a necessary consequence of the law of gravitation. The phenomenon of the T. is, indeed, a case of perturbations, of exactly the same nature as the irregularities which the action of the sun produces in the motions of the moon. If we compare the attraction of the moon upon a particle of the earth's surface with the attraction exerted upon the earth as a whole, we readily see that, according as the particle is on the nearer or further side of the earth, the former attraction is greater or less than the latter; and it is to this *difference* of attraction, to which the waters yield, that the whole phenomenon of T. is due. The nearer waters are driven *towards* the moon, the further waters *away* from it. If the earth were spherical and uniformly covered with water, the tendency would be to make the water arrange itself in the form of a spheroid with the longer axis pointing towards the moon; and did the earth always present the same face to the moon, this would be rigorously the case. Such is the *equilibrium* theory of T., as originally given by Newton. It accounts so far for the phenomena, such as the simultaneous existence of high water at places diametrically opposite, but does not even approximately correspond to the true state of affairs. Newton was fully aware of this, and indeed has given the solution of the problem upon other and truer assumptions. If the hypothetical earth covered uniformly with water is rotating, so as to present each point of its surface successively to the moon, each particle of water will be moving with a certain momentum which will be suffering retardation or acceleration according to its position relatively to the moon. The longer diameter of the water ellipsoid will consequently not point in the direction of the moon; and the result will be the formation of two diametrically opposite waves, flowing round the earth in a direction contrary to its rotation. This is the kinetic theory, which forms the basis of Laplace's theory of T. It also fails in practical application, since the continuity of the surface waters on the earth is very much broken by the distribution of land. More recently Young and Airy have approached the question as one of wave motion, basing their theory upon the motion of waves in canals. Till now we have been regarding the moon as the sole tide-producing agent, but it is evident that the sun must have a similar action, though not so marked because of its much greater distance. It was proved by Newton that the disturbing forces exerted by two bodies upon the same particle are directly as their masses, and inversely as the cubes of their distances; hence the ratio of the disturbing force exerted by the sun to that exerted by the moon 7 : 16. The principal tidal wave is that caused by the moon, but upon it must be superposed that due to the sun. When the sun and moon are in *syzygy, i.e.*, at times of new and full moon, their tidal waves will be superposed crest upon crest, and the effect will be what is called a *spring-tide*. When they are in *quadrature*, trough will coincide with crest, the lunar tide will be partially neutralised by the solar tide, and the result will be the so-called *neap-tide*. The average spring-tide will be to the average neap-tide as $16 + 7 : 16 - 7 = 23 : 9$. Besides this effect in amplitude, another effect is caused by this combination of the T., namely the *priming* and *lagging* of the T. For when the two vertices do not coincide, the maximum of the resultant tidal wave will be at a point intermediate to the vertices, so that the time of high water will be now in advance now behind the time it would have been had the moon been the sole agent. Not only, then, are the waters of the ocean subject to diurnal and semi-diurnal oscillations, but these are subject to a monthly, semi-monthly, and even annual variation, besides being more or less affected by prevailing winds and coast configuration. The height of the tidal wave which circulates round the earth is not great—at most some 7 feet, a very small quantity compared to the size of our globe. In estuaries, bays, creeks, straits, &c., however, the difference between high and low water is much greater than this—as much as 50 feet in the Bay of Fundy, Nova Scotia. The explanation of such phenomena is to be found in the momentum with which the water is pushed forward by the advancing wave. In such a sea as the Mediterranean, which is all but cut off from communication with the great oceans, and which is itself not sufficiently extensive to be very perceptibly acted upon by the sun and moon, the T. are very small, not exceeding a few inches.

The attempt to establish a complete theory from abstract principles has proved a failure; and the only true method by which to get an insight into the particular laws which govern tidal action at any given place is continued observation. By means of Sir William Thomson's tide-gauge a graphical representation of the tidal oscillation at any place can be easily obtained; and by harmonic analysis of the curve, the constituent factors may be easily discovered, and the comparative effects of their several causes estimated. One efficient cause in retarding the T. has not been mentioned, namely fluid friction, which, as first noticed by Kant, must act as a continual *break* to the earth in its rotation; and this gradual slackening in the earth's speed of rotation must go on until the day is of the same length as the lunar month, when matters will be as required in the equilibrium theory given above. See Newton's *Principia* (Book III., prop. 24, 36, 37); Laplace's *Mécanique Céleste*; *Young's Works* (edited by Peacock, 1855), and Airy's 'T. and Waves' in the *Encyclopædia Metropolitana*.

Tie, in music, also called a bind or ligature, is a curved line drawn over two or more notes on the same degree of the stave,  indicating that the second note is not to be sounded separately, but is to sustain the first. When dots are associated with the bind  the notes are not tied, but are to be played *mezzo-staccato*, in a detached but not crisp manner. A line placed over notes of different degrees  is called a

slur, and indicates that the notes are to be played *legato.* To prevent confusion between tied and slurred notes, Sir W. S. Bennet introduced the sign ⌐¬ instead of ⌒ for a tie, an example that might have been more generally followed with convenience.

Tieck, Ludwig, a German novelist and poet, the most brilliant representative of the romantic school, was born at Berlin, 31st May 1773. He studied at the Universities of Halle, Göttingen, and Erlangen. After spending some years at Jena, Dresden, and Munich, T. was forced on account of his health to go (1805) for a year to Italy. On his return he lived principally at Ziebingen till 1819, when he went to Munich. When Friedrich Wilhelm IV. of Prussia ascended the throne T. was summoned to court, received a considerable pension, and was honoured with the title of privy councillor. He died at Berlin, after a long and lingering illness, 28th April 1853. T.'s long life was a period of almost continuous literary activity. It falls naturally into two periods. In the first the romantic 'note' is heard much more distinctly than in the second, and the subjects are taken from the history, folklore, or superstitions of the Middle Ages. The mystic element is everywhere apparent. *Abdallah* (Berl. 1795), *William Lovell* (3 vols. Berl. 1795), and *Peter Lebrecht* (2 vols. Berl. 1795-96), were his first considerable works. These are chiefly noteworthy for the promise of excellence which they contain. They show strength, but it is wild and immature. In rapid succession followed *Peter Lebrecht's Volksmarchen* (3 vols. Berl. 1797); the comedy of *Die Verkehrte Welt; Romantische Dichtungen* (2 vols. Jena 1799-1800), containing *Zerlino*, a clever attack on the Anti-Romanticists in the form of a continuation of the fairy tale of *Puss in Boots*, which he had already treated in the *Märchen; Leben und Tod der Genovera*, a legend of the Middle Ages exquisitely reproduced. A translation of *Don Quixote* (4 vols. Berl. 1799-1801) next engaged his attention, and this was followed in 1804 by *Kaiser Octavianus*, one of the best examples both of the merits and the faults of the romantic school. A pause followed, and it was not till eight years later that his next work, *Phantasus* (3 vols. Berl. 1812-15, new ed. 1844), appeared. This was really a new edition of the *Volksmärchen*, but considerably enlarged and improved, and is T.'s best work. It is chiefly a reproduction of old German legends and popular stories, bound together by a number of critical dialogues. Among the best are 'The Trusty Eckart,' 'The Runenberg,' and 'The Elves.' The last is the finest modern fairy tale in existence; it was translated, along with stories of T., by Carlyle (1827). T.'s second period is distinguished by a more moderate phantasy, an almost entire abandonment of the magic element, and an approximation to the form of the modern historical novel. In a new edition of Ulrich von Lichenstein's *Frauendienst* (Tüb. 1815), and in the *Altdeutsches Theater* (2 vols. Berl. 1817), we have the results of historical researches in old German literature. The *Aufruhr in den Cevennen* (Berl. 1826), *Der Junge Tischlermeister* (2 vols. Berl. 1836), and *Vittoria Accorombona* (2 vols. Bres. 1836, new ed. 1841), are three novels, of which the first is one of the best and the last one of the worst things that T. ever wrote. A prolonged study of Shakespeare and his surroundings resulted in *Das Altenglische Theater* (2 vols. Berl. 1811), *Shakespeare's Vorschulte* (2 vols. Leip. 1823-29), the completion of the magnificent translation of the great dramatist which A. W. Schlegel had begun, and *Dichterleben* (in the *Urania* for 1826), a brilliant novel, in which Shakespeare and the greatest of his contemporaries are introduced. T. is now little read in Germany; the current of his country's literature has turned in another direction. Yet he was one of those men who have secured a permanent place in literature. The Middle Ages existed in his mind as a living reality, and he has reproduced with vivid exactness the beauties of a long-distant past. He has the best characteristics of the romantic school—its regard for nobleness of character and purity of life, its love of the beautiful in nature, its childlike simplicity that often contains so deep a meaning. He has often its faults—obscurity, want of form, irregularity of development. His genius was wild and sometimes extravagant, but it was also deep, rich, and various. Collections of T.'s writings have been published in the following forms:—*Gedichte* (3 vols. Berl. 1821; new ed. 1841), *Sämmtliche Werke* (20 vols. Berl. 1828-42); *Nachgelassene Schriften*, edited by Köpke (2 vols. Leip. 1855). See Köpke's *Ludwig T. Erinnerungen aus dem Leben des Dichters* (published with the last-named work), and Hoffman's *Ludwig T., eine Literarhistorische Skizze* (Nürn. 1856).—**Christian Friedrich T.**, an eminent sculptor, brother of the foregoing, was born at Berlin, 14th August 1776, and died 14th May 1851. He executed busts and statues of a large number of the most eminent of his countrymen, and had a share in the planning of many of the finest buildings in the German capitals.

Tiel, an old town of Holland, in Gelderland, on the right bank of the Waal, 20 miles W. of Nijmegen. It has good docks and quays, and carries on an active trade in the produce of the fertile Betuwe. Pop. (1877) 7598.

Tien-tsin, an important city and river-port of China, province of Chih-le, on the right bank of the Peiho, 68 miles from Taku at its mouth, and 80 S.E. of Pekin, of which it is the port. It is surrounded by a wall, and most of the houses are built of sun-dried bricks. Many of the streets are well paved and spacious. By the destruction by fire of an asylum for women and children, 2000 lives were lost, according to a telegram from Shanghai dated 2d February 1878. The foreign settlement included in 1877 the residences of official consuls for Great Britain, France, Germany, Russia, and the United States, of an official vice-consul for Japan, and of merchant consuls for Sweden and Norway. The construction of a telegraph line between T. and Taku is in progress (1879), and the Chinese officials are promoting a scheme for the formation of a railway between the two places. The temperature at T. ranges from 106° F. to 6° below zero, and the river is generally frozen from 15th December to 15th March, during which period business is actively carried on by sledges. In 1877 there entered and cleared the port 924 vessels of 528,308 tons, and of these 404 of 293,694 tons were Chinese, 382 of 187,882 tons British, 78 of 22,626 tons German, and 36 of 17,118 tons American. In 1876 the Chinese Steam Company, largely subsidised by the Government, took over the American 'Shanghai Steam Company,' and the purchase raises the Chinese returns by 211 vessels and 145,387 tons. The value of imports amounted (1877) to £6,347,771, including £4,020,614 of 'native' imports; and of exports to £534,963. The foreign imports are chiefly cotton and woollen goods, metals, and opium, while among the sundries appear 13,002 gross of matches, 4190 boxes of window glass, and 213,000 of needles. Rice, wheat, millet, tea, &c., are native imports; the exports include tobacco, dates, rhubarb, camels' wool, and straw braid. The last two articles are now the specialties of the port. Estimated pop. (1877) 950,000. T. was opened to foreign trade in 1860.

Tierce. See FENCING.

Tier'ney, George, a London merchant's son, was born at Gibraltar, 20th March 1761, from Eton passed to Peterhouse, Cambridge, and graduated LL.B. (1784). Called to the bar, he published *The Real Situation of the East India Company* (1787), and in 1796 entered Parliament, where he rose by his powers of debate to be leader of the Whigs. In 1798 he fought a duel with Pitt, on whose retirement from office in 1803 T. was appointed Treasurer of the Navy, subsequently becoming Secretary of State for India and President of the Board of Control (1806), head of the Opposition (1817), and Master of the Mint (1827). He died in London, 25th January 1830.

Tierr'a del Fue'go (Span. 'land of fire'), an archipelago separated from Patagonia by the Strait of Magellan, consists of 11 large and 20 small islands, with an aggregate area of about 26,570 sq. miles, of which the largest island, called King Charles's South Land, forms three-fourths. The group appears to be a prolongation of the adjacent continent, like which its western coasts are indented by deep inlets, while the eastern coast is tolerably regular. All the islands are rugged and mountainous, and Mr. Darwin says that 'to find an acre of level land in any part of the country is most rare.' The highest peaks are Mounts Sarmiento (6910 feet) and Darwin (6800 feet). Impenetrable forests clothe the mountain sides from the water's edge to a height of 1200 feet, and are succeeded by alpine plants up to 3500 feet, which is the limit of perpetual snow. Volcanic products abound almost everywhere, whence the name of the group. The climate is extremely wet and stormy all the year round, and the ground is covered with a thick bed of always soaking peat. The forests are composed principally of the evergreen *Fagus betuloides*, with frequent specimens of the deciduous Antarctic

beech (*Fagus antarctica*), and the handsome Winter's-bark tree (*Drimys Winteri*). The dog, guanaco, otter, seal, and whale are the only mammals found, but waterfowl of many kinds are very numerous. The aborigines, who are among the lowest in the scale of humanity, are of a coppery-red colour, with black hair, and daub themselves with white paint. The life of the natives is a constant struggle for existence, their food consisting of shell-fish, berries, and fungus, with fish and blubber when obtainable. Their canoes are of the most wretched kind, and they are ignorant of fish-hooks. Their numbers probably do not much exceed 2000. An attempt made in 1850–51 to establish a mission station in T. D. F. resulted, through mismanagement at home, in the death of the entire party of seven by starvation. Another expedition with a similar object, made in 1854–55, also proved a failure, but the labours of Bishop Sterling of the Falkland Islands were reported in 1878 to have been successful in stirring the natives to habits of industry.

Tiers État. See STATES-GENERAL.

Tif'lis, a government of Asiatic Russia, extending on both sides of the river Kur from the central chain of the Caucasus Mountains on the N. to the Armenian plateau on the S. Area 15,622 sq. miles; pop. (1873) 662,859 (24 per cent. Mohammedan). Steppes and fertile plains are found in the centre, but much of the surface is mountainous, covered with offshoots from the Caucasus and Mount Ararat, reaching in some peaks to 12,000 feet. The soil is fertile and yields abundant tobacco, cotton, indigo, wheat, and fruit. Numerous rich petroleum springs and mineral wells exist, and excellent timber is produced from the extensive forests of oak, elm, maple, and chestnut.—**T.**, capital of the preceding government, and chief city in the territory of the Caucasus, lies in a narrow valley on both sides of the Kur, 184 miles E.S.E. of Poti by rail. In its architecture and in the manners of its inhabitants the city presents a singular mixture of Asiatic and European features. The city is the seat of the civil and military authorities of Transcaucasia, and has 42 churches (23 Armenian), 2 mosques, a gymnasium, and several upper schools, a library, a botanic garden, a hospital, and a theatre. It has active manufactures of woollens, silks, cottons, armour, and leather, and is the emporium for the important Russian trade with Persia. It is already connected with Teheran by telegraph, and the Russian government has recently arranged to connect it also by rail. In 1876 there were imported from foreign countries and cleared at T. goods to the value of 1,647,266 roubles, of which the principal articles were sugar 666,700 roubles, manufactures 460,600, metals 77,500, tea 59,980, tobacco and cigars 59,890, chemicals 51,620, paper and stationery 26,920, and wines 15,856. Pop. (1873) 70,591.

Ti'ger (*Tigris regalis*), a well-known species of carnivorous mammalia inhabiting Southern Asia generally, and also Java and Sumatra. The distinctive characteristics of the T., of which but one well-defined species (the royal or Bengal T.) is known, are the absence of a mane, and of any tuft on the tail, a leonine shape generally, but with greater symmetry, the fore parts of the body exhibiting no such large development as in the Lion (q. v.). The colour of the T. is very conspicuous and characteristic. The ground colour of the fur is a reddish-yellow hue, often approaching the tawny in its tint, while disposed upon this ground are black stripes of crescentic form, which run transversely to the long axes of the body. The under parts are white, and the tail, like the body, is encircled with dark rings. Occasional specimens of the T. have been found in which these markings have given place to a uniform white colour. The T. is even more bloodthirsty and dangerous than the lion. It is more lithe and agile; its spring is more stealthy and powerful; and in disposition it is treacherous. It usually lies concealed during the day and hunts at night. Its favourite haunt is close by some water pool, from a near eminence of which it may spring upon the animals which come to drink. Sometimes the T., growing bold by successful forays, approaches the habitations of men, and may carry off sheep, cattle, and even attack human beings. T.-hunting is a dangerous but highly-exciting Indian sport. The animal is pursued on elephants, and the sportsmen and their huge bearers are occasionally liable to suffer from the spring and furious onset of their game. The T. is also captured in pit-falls, and a curious method of taking it is to smear leaves with bird-lime; the T. treading on the leaves, then smears its face with the bird-lime to get rid of the leaf, and thus effectually blinds itself, when it becomes an easy prey to the rifle. The length of a full-grown Bengal T. from the tip of the muzzle to that of the tail, is about 15 feet, but larger specimens are by no means unknown. In ancient times the T. was exhibited in the shows and spectacles of the Roman emperors. A hybrid offspring is not unfrequently produced by the union of the male lion and the tigress, the cross being striped and not maned.

Ti'ger Bee'tle (*Cincindela campestris*), a species of beetle belonging to the Pentamerous section of the order *Coleoptera* (q. v.). The head is broader than the *prothorax*, the jaws are long and curved, and the legs are slender. The colour is brownish, marked with lighter dots and stripes. The T. B. is common in sandy places, and on the shores of rivers and ponds. It runs swiftly, and is difficult to capture. *C. campestris* and *C. vulgaris* are familiar species.

Ti'ger Cat, a term used to denote many species of smaller *Felidæ* or cats resembling the Tiger (q. v.) more or less closely. The ocelot and serval are thus named; but perhaps the most distinctive genus included under this designation are the Margay or T. C. (*Felis tigrina*), and the Chati (*Leopardus mitis*), both of which belong to S. America. The Chati attains a length of about 2 feet, the tail measuring an additional 11 inches.

Ti'ger Flower (*Tigridia*), a genus of bulbous *Iridaceæ*, named from the flowers of *T. Pavonia* being richly spotted on a yellow or red ground. Their beauty, though evanescent, makes them favourites in gardens. They are indigenous to tropical America.

Tigridia Pavonia.

Tighe, Mrs. Mary, an Irish poetess, born in Dublin, in 1774, and married her cousin, Henry T., of Woodstock, M.P., in 1793. Though her poem *Psyche, or the Legend of Love*, was privately printed by C. Whittingham (Lond. 1805), it was only after her death, which took place March 24, 1810, that her writings were given to the world. The first edition was in 1811, and they have been frequently reprinted. The *Psyche* is written in the Spenserian stanza; and at least, by Leigh Hunt's admission, occasionally contains a fancy not unworthy of a pupil of Spenser. Her other poems are short occasional pieces, frequently of a religious cast. It is probably as the subject of Moore's lyric, 'I saw thy form in youthful pride,' and of Mrs. Hemans's *Grave of a Poetess*, that Mrs. T. is destined to be longest remembered.

Tigré. See ABYSSINIA.

Ti'gris (Old Pers. *Tigra*, 'an arrow,' Assyr. *Chiddekel*, Armen. *Deklath*, Arab. *Didschle*), next to the Euphrates the greatest river of Asiatic Turkey, rises on the S. slope of the Armenian Taurus range in Kurdistan, to the S. of Lake Goljik. It has a sinuous course in a S.-easterly direction, almost parallel to that of the Euphrates, which river it joins at Kurna, after a course of 1060 miles. The joint stream, called the Shat-el-Arab (q. v.), after a further course of 90 miles, enters the head of the Persian Gulf. In its upper course the T. flows through fine pasture-land, frequented by nomad Kurds and Arabs, and from Diarbekir, where it becomes navigable for small craft, to Mosul, a distance of 200 miles, its banks are highly cultivated in some places. Below this point, again, as far as Bagdad (250 miles), it traverses unpeopled wastes, while from Bagdad to its mouth the steep banks are overgrown with high reeds and brushwood, and are haunted by lions and other beasts of prey. Its affluents, the Bitlis, Great and Little Zab, and Dyala, all flow from the highlands to the N., the country separating it from the Euphrates being a streamless waste. The chief places on the T. are Diarbekir, Mosul, and Bagdad, and the ruins of Nineveh, Seleucia, Ctesiphon, and Opis. Like the Euphrates, the T. rises in

spring with the melting of the snow on the Armenian mountains; and during the latter half of May, when the flood is at its height, the whole country between and beyond these rivers, for over 100 miles between Bagdad and Bussorah, is converted into a lake. The 'arrowy' stream either loses less water by irrigation or receives more from its affluents than the Euphrates, for it is the larger of the two at the point of confluence.

Til'burg, a town of the Netherlands, province of S. Brabant, 48 miles S.E. of Dortrecht by rail. T. has an archbishop's palace, 4 Roman Catholic churches, a Reformed church, a synagogue, and large manufactures of cloth, cottons, woollens, carpets, and leather. Pop. (1875) 25,397.

Til'bury Fort, on the Essex bank of the Thames, opposite Gravesend, was founded by Henry VIII. as a blockhouse and strengthened by Elizabeth, who here harangued the troops mustered to repel the Armada (1588), as also by Charles II. in 1667. It is now a rectangular brick building, girt by a fosse, and had a garrison in 1871 of 148 men.

Tiles (Fr. *tuiles;* Lat. *tegulæ*, from *tego*, 'I cover') are manufactures in burnt clay, used for surfaces, such as floors, walls, and roofs. There are also oven T., which are perforated for the passage of heated air; and drain T., used extensively in agriculture. T. also vary very much in quality, the commoner kinds being of the same material as ordinary bricks, although generally a purer and tougher clay is used. Encaustic and other ornamental floor T., on the other hand, are made of very superior materials, faced with fine pottery 'slips,' and moulded with the greatest care; and the 'majolica' painted and glazed T., now extensively used for walls, grates, and mantel-pieces, are in many instances works of art. See ENCAUSTIC T.

Tile'stones, a group of rocks referred by Sir R. Murchison to the base of the Devonian system, and subsequently looked upon as 'Transition beds' between that formation and the Silurian. Now, however, from the evidence of their organic remains, they are usually classed with the Ludlow formation, of which they form the highest subdivision. They are typically displayed at Downton Castle near Ludlow, and are hence often known as 'Downton beds.'

Tilia'ceæ, a natural order of thalamifloral polypetalæ, numbering about 350 species of trees, shrubs, or rarely herbs. The properties are usually mucilaginous, and the inner bark of many species yields fibre, thus pronouncing affinity with *Malvaceæ* (q. v.). The order, which is chiefly tropical and sub-tropical, is in these zones spread over both the New and the Old World, with one extra-tropical genus (*Tilia*) in the northern, and another (*Aristotelia*) in the southern hemisphere. To this family belong *Berrya ammonilla* of Ceylon which yields Trincomalee wood, the lime-trees of Europe, and *Corchorus capsularis* furnishing the Jute (q. v.) of commerce. The fruit of various species of *Grewia* is eaten in India, their bark-fibre serves for cordage, &c., and their wood is useful timber. In the large genus *Elæocarpus* an excellent and permanent dye is obtained from the Hinau (*E. Hinau*) of New Zealand. *Luhea divaricata* of Brazil supplies a very close-grained light wood, and the bark of *L. grandiflora* is used for tanning.

Till. See BOULDER CLAY, DRIFT, OR TILL.

Tilland'sia. See BROMELIA'CEÆ.

Tille'mont, Louis Sebastien le Nain de, born in Paris, November 30, 1637, was educated at Port-Royal, and after receiving the tonsure proceeded (1656) to the seminary of Beauvais. Ordained sub-deacon in 1672 and priest in 1676, he withdrew to the abbey of Port-Royal (1677), and on its dissolution two years later settled upon his family estate of Tillemont, between Vincennes and Montreuil. To visit Antoine Arnauld (q. v.) and other Jansenist exiles, T. travelled to Belgium (1681), and he died in Paris, January 10, 1698. Of T.'s historical works—impartial, accurate, but prolix and dry—the chief are *Histoire des Empereurs et des autres Princes, qui ont régné pendant les six premiers Siècles de l'Église* (6 vols., 1690–1738); and *Mémoires pour servir à l'Histoire Ecclesiastique des six premiers Siècles* (16 vols. 1693–1712). See the works cited under PORT-ROYAL, and Tronchay's *Vie de T.* (Nancy, 1706).

Till'er, the handle of the Helm (q. v.), by which the Rudder (q. v.) is turned.

Tillicoult'ry, an industrial town of Scotland, county of Clackmannan, on the Devon, 2 miles E. of Alva and 9 N.E. of Stirling by rail. It is the seat of an important woollen trade, and has several large mills engaged in the production of shawls, plaids, and tartans. Coal and limestone are extensively wrought in the vicinity. There are five churches. Pop. (1871) 3745.

Tillodon'tia, an order of Mammalia recently constructed by Professor Marsh of America to include certain peculiar extinct quadrupeds, the remains of which occur in the Eocene Tertiary rocks of the United States. The molar teeth in the T. have grinding crowns, and resemble those of *Ungulata*. Small canine teeth are developed, and each jaw has two very long incisors, similar to those of *Rodentia*, these growing, like the incisors of the last-named forms, from persistent pulps. The feet, like those of bears, are *plantigrade*, and possessed of five toes each. The femur has a third trochanter. Of this curious order the typical genus is *Tillotherium*, in which form the characters of ungulata, carnivora, and rodentia appear to be united. The average size of these remarkable extinct mammals was that of the Tapir.

Till'otson, John, one of the most eminent of Anglican divines, was born of Puritan parents at Sowerby, near Halifax, in 1630. He was educated at Cambridge for the clerical profession, and took the degree of M.A. in 1654. While he was at the university, and during the years that immediately followed, careful reading and intercourse with cultivated men like Cudworth, More, Smith, Rust, and Wilkins, had their full effect on a mind naturally susceptible to liberal impressions, and consequently in 1662 he felt no difficulty in conforming to the Act of Uniformity. His subsequent rise was rapid. In 1663 he became rector of Keddington, in 1664 preacher of Lincoln's Inn, in 1670 prebendary, and in 1671 Dean of Canterbury. T. gave in his adhesion to the Revolution. He enjoyed the intimate friendship and respect of King William, who almost forced upon him in April 1691 the see of Canterbury, vacant by the deposition of Sancroft. T.'s episcopate was a troubled one, for his moderate opinions made him distasteful to the extreme men of all parties; but he performed the duties of his important office with tact and discretion. Among other things he planned a scheme for restoring a large body of dissenters to the Church, but he was not spared to carry it out. He died 20th November 1694. In English literature T. is best known by his *Sermons*, once immensely popular, though now little read. They brought his widow 2500 guineas. They are moral discourses containing plain homely truths in distinct direct language. Their popularity was partly at least due to the fact that they very fairly represented one phase of that theological Utilitarianism which in his time was the real belief of the average English mind. T.'s works were published in 3 vols. Lond. 1707–12; the best edition is by Birch (3 vols. 1752). See also Birch's *Life of T.* (Lond. 1752).

Till'y, Johann Tserclæs, Graf von, one of the most notable generals of the Thirty Years' War, was born in Brabant in 1559. He was at first educated under Jesuit supervision for the priesthood, but a strong bias towards a military career soon showed itself, and he abandoned the church for the army. He served under Alva during the revolt in the Netherlands, and afterwards with distinction in Hungary. Maximilian, Duke of Bavaria, appointed T. commander of his forces, and in 1620, two years after the beginning of the Thirty Years' War, he utterly routed the Bohemians. During the next period of the contest he defeated in turn the two Protestant leaders. In 1622 T. drove from the Palatinate Christian, Duke of Brandenburg, and in August next year defeated him in a three days' engagement at Stadtloo in Münsterchen. In 1625 he led the army of the Catholic League against Christian IV. of Denmark, who commanded the army of Lower Saxony, and defeated him in the battle of Lutter. Along with Wallenstein (q. v.) he forced the Danish king to agree to the disgraceful peace of Lübeck (1629). Next year Wallenstein was forced to resign the command of the imperial forces, and T. succeeded him. In May 1631 T. sacked with ferocious cruelty the town of Magdeburg. As he himself complacently wrote, since the destruction of Troy and Jerusalem nothing had equalled it. Gustavus Adolphus (q. v.) was too late to save, but not to avenge, Magdeburg. In September 1631 he defeated T. at Breitenfeld, and again at Rain

on the Lech. In both battles, T. was wounded. He died at Ingolstadt, 30th April 1632, a few days after his second defeat. T. was an able general, but a man of narrow intellect. Not personally ambitious, nor caring for money, he was a fanatical Roman Catholic, ready to sacrifice everything for his church. See Klopp's *T. im Dreizigjährigen Kriege* (2 vols. Stutt. 1861).

Til-Seed. See RAM-TIL.

Til'sit, a town of Prussia, province of Preussen, at the junction of the Tilse with the Memel or Niemen, which is crossed by a fine railway bridge (1875), 53 miles S.E. of Memel by rail. It has a Schloss (built 1537, partially burnt 1876), a fine Rathhaus, four churches, two hospitals, a gymnasium (since 1586), a Realschule of the first class (1839), and a large barrack. T. manufactures paper, leather, linens, woollens, and beer, has iron-founding and sugar-refining, and considerable commerce in horses, timber, corn, and produce. Pop. (1875) 19,787. T. is historically interesting as the place where, on a raft in the river, the peace of 1807 was concluded between Napoleon, Alexander, and Friedrich Wilhelm III., by which the last was deprived of one-half of his dominions.

Tim'ber (Old Eng. *timber:* Comp. Ger. *zimmer*, perhaps allied to Gr. *demō*, 'I build') means all kinds of wood, common or ornamental, used in building. T. in carpentry denotes a piece of wood in a frame; and in shipbuilding one of the curved ribs which spring up from the keel. T. sawn, split, sliced, or shaved is called *lumber* in America. The trade in T., already of enormous extent, is annually expanding.

Law Regarding T.—It belongs to the owner of the land. An ordinary lease does not empower the tenant to cut T., but he is entitled to cut and use the underwood, and also to take sufficient wood for repairs (see HAYBOTE). A life-tenant is also entitled to take wood for repairs, and to T. which has been blown down; but he is not entitled to fell trees, unless the estate has been given to him without Impeachment of Waste (q. v.). If the root of a tree extend under the soil of two proprietors, the tree belongs to the owner of the land in which it was sown or planted. Stealing trees or injuring them is a statutory offence, punishable by fine, imprisonment, or penal servitude.

Tim'ber Trees are all trees yielding wood used for constructive purposes. The trees indigenous to a country are first utilised, but as knowledge and means accumulate, the forest vegetation of the world at large becomes available for a wealthy nation. The temperate regions yield the largest supply of T. T.; the oak, elm, beech, ash among exogenous trees, and the pine, spruce, larch, and other conifers in the northern hemisphere, the *Eucalypti* of Australasia, and the valuable produce of New Zealand in the southern hemisphere, being of the highest importance; whilst from the tropical zone come teak, mahogany, and many others. The destruction of T. T. has caused a marked deterioration in the productive capacity of those countries where it has been carried on to excess. All civilised governments now insist on conservation; trained officials regulate the felling, and see that the devastated districts are re-stocked.

Tim'brel (a corruption of Sp. *timbal*), a drum or tabour, used from a very remote age. It is somewhat like a tambourine.

Timbuk'tu, a city of the Sudan, in 17° 37′ N. lat. and 3° 5′ W. long., 6 miles N. of the Niger at the most northerly point of its course. The town is triangular in shape, and at present is less than three miles in circumference, though formerly it was much larger. The wall or rampart which surrounded it was destroyed by invaders in 1826, and has not been rebuilt. The streets are for the most part straight and unpaved, with a gutter in the centre. Most of the houses are of clay, and some are two storeys high, a very unusual thing in Negroland. On the outskirts there are a good many conical huts of matting. Of the mosques, two are especially noteworthy from their great size and imposing appearance, viz., that of Sankoré in the northern, and the Great Mosque in the western angle of the town. The latter is 286 feet long and 212 feet wide. T. has also two markets. The climate is unhealthy, and the surrounding country being desert, or nearly so, all supplies of food are brought by the Niger from Sansanding (q. v.) to Kábara, the port of T. The manufactures of T. are confined to a little iron work, and to leather bags, pouches, cushions, &c., made by the Tuarick women. The place owes its importance entirely to its commercial situation, which makes it the *entrepôt* for the trade between the N. and S. of the Sahara. In addition to the Niger there are two main channels by which commerce flows to T., viz., the caravan routes from Morocco on the N., and Ghadames on the N.E. The principal articles of trade are gold in rings, salt, English calico, red cloth, cutlery, looking-glasses, rice, negro corn, kola nuts (a substitute for coffee), ginger, tobacco, dates, and tea. The resident pop. of the town is about 13,000, but in the trading season, from November to January, is from 5000 to 10,000 more. T. was founded towards the end of the 11th c., and became known to Europeans in 1373. See BARTH.

Time, in music. Every musical phrase is divided into certain portions called bars, and the T. depends upon the number of beats given to each bar. If there are four or eight beats in a bar, we call the T. common T.; if there are three beats, triple T. If the beats are of the value of dotted notes the T. is compound. (See MUSIC for T. signatures.) Formerly triple T. was called perfect T., and was indicated by the signature O for perfection. Common or imperfect T. was indicated by a semicircle, which has now taken the shape of the letter C. For other meanings of T. in music, see TEMPO.

Time. According to Clerk Maxwell, the idea of T. is 'the recognition of an order of sequence in our states of consciousness.' By the exercise of memory, the events in one's experience may be arranged chronologically, and by intercourse with others, and comparison with natural phenomena which recur in a uniform rythmic manner, all events whatever may be systematically arranged according to their place in T. The measurement of T. is involved in the statement of Newton's First Law (see MOTION, LAWS OF). Our ordinary units depend upon the motion of the earth; but it would be possible to get a more general unit, say the T. of vibration of a wave of light of a definite wave length and refrangibility. See SPACE AND T., YEAR, DAY, &c.

Time'-Tables. See BRADSHAW'S RAILWAY GUIDE.

Timo'leon, a famous Greek general, was born of a noble family at Corinth in the beginning of the 4th c. B.C. He saved the life of his brother Timophanes in a battle with the Argeians; but his patriotism was stronger than his personal affections, and when that brother sought to establish a 'tyranny,' T. procured his assassination, 366 B.C. Though this act was generally approved, yet his own remorseful misgivings and his mother's reproaches preyed upon his mind, and for twenty years he lived in close retirement. In 344, when T. was about fifty years old, ambassadors from Syracuse arrived at Corinth imploring aid against Dionysius the younger, who was seeking to recover his authority over their city. T. was made leader of the Corinthian expeditionary force, and by stratagem, diplomacy, bravery, good generalship, and, perhaps most of all, good fortune, ultimately made himself master of Syracuse, repelling the efforts of the Carthaginian allies in a great battle at Crimissus (B.C. 339). In six years he succeeded in clearing Sicily of tyrants, and in establishing free democratic constitutions. His work now done, he resigned his power and lived a private citizen profoundly respected, till his death in 337-336. His brilliant successes, his constant good fortune, and the tragic story of his disinterested sacrifices, make T. a unique figure in ancient history. Plutarch and Cornelius Nepos have written his life. His career has excited less interest in modern times. See *T.'s Rückkehr nach Korinth*, by Conz (Stuttg. 1801), and Arnoldt's *Ueber die Quellen zu T.'s Leben* (Gumb. 1848).

Timor', an island in the Malay Archipelago situated in 9° 10′–10° 25′ S. lat., 124° 25′–127° 10′ E. long., and 300 miles long, with an average breadth of 50 miles. Pop. about 400,000. Though forming one of the Javan chain of islands, it approximates more nearly in soil, climate, and animal life to Australia, from which it is now 300 miles distant, though Mr. A. R. Wallace argues that the strait between the two was at one time only 20 miles wide. T. is traversed by a mountain-chain whose highest summit is Mount Alas (11,800 feet), and average height 6000 feet. T. Peak, near the centre of the island, is a volcano which has been quiescent since 1638. The extremities of the island consist largely of

upraised coral rock. The soil is usually poor and shallow, and the lowlands are very parched and barren during a great part of the year. Trees, mostly of Australian species, grow to a good size, but are nowhere numerous enough to be called a forest. Rice grows well in the swampy coast districts, maize on the dry lowlands, and coffee on the mountain-slopes up to 2000 feet. At an elevation of 3000 to 4000 feet potatoes and wheat do exceedingly well, the wheat in particular being of the finest quality. Sheep thrive on the mountains, and ponies everywhere. The indigenous fauna includes 22 species of mammals and about 200 species of birds, few of which are of gay plumage. Copper, gold, and naphtha are known to exist, but not in remunerative quantities or localities, the great want of the island being roads. The Dutch have settlements at the western end of T., the capital being Koepang, with a mixed population of 3500. It is the residence of a governor, whose jurisdiction extends to the other islands of the chain, as far W. as Sumbawa. The Portuguese own the eastern part of the island. The natives, who are practically almost independent, are of a Papuan type in the mountains, but on the coast there has been a considerable infusion of Malay, Chinese, Portuguese, and probably also Hindu blood. The leading exports are sandalwood, tortoise-shell, bees'-wax, horses, and wheat.

Timor-Laut' ('Timor lying to seaward'), a small group of islands in 6° 40'-8° 23' S. lat., 130° 26'-132° E. long., 260 miles E. of Timor. It consists of eight considerable islands of volcanic formation, and a great number of coral islets. The chief islands are T.-L., Larat, and Tenimber; the first, which is by far the largest, measuring 80 miles by 25. All three are very mountainous. The group lying within the range of the damp S.E. winds which blow through Torres Strait (q. v.), has a much more humid climate than Timor, and luxuriant forests ascend to the very summits of the mountains. The natural wealth of the islands is as yet undeveloped, and tortoise-shell and Bêche-de-Mer (q. v.) are the chief articles of trade. The natives resemble those of north-western New Guinea in appearance, and are fierce and treacherous.

Tim'othy, Epistles to, along with the **Epistle to Titus,** receive the name of the Pastoral Epistles, because they contain instructions regarding the oversight of churches. Until the last half-century they were almost universally acknowledged to have been written, as they profess to have been, by St. Paul, but some recent critics deny their authenticity for various reasons, of which the following are the chief:—1, That the way in which they make Paul act and speak is against it; 2, the manner in which Timothy and Titus are described is suspicious; 3, the general tone and character of the epistles are different from Paul's; 4, unpauline sentiments occur; 5, they exhibit many proofs of a post-apostolic origin; 6, the universality of God's favour expressed is unpauline; 7, numerous passages show the use of Paul's acknowledged writings; 8, Luke is quoted as Scripture (1 Tim. v. 18); 9, the passage 1 Tim. iii. 16 (*God*) is abrupt; 10, there are numerous and striking words and phrases peculiar to those epistles; 11, the language and general structure of periods are different from Paul's; 12, the false teachers spoken of betray a post-apostolic time. Most of these averments are strenuously challenged by conservative critics; some of them, it is urged, cannot be substantiated, others are positively without foundation, and others again are irrelevant.

Tim'othy Grass (*Phleum pratense*) is one of the most valuable of perennial fodder grasses, and particularly on tenacious, strong, and rather moist soils should form a considerable proportion of the seed sown either for alternate husbandry or permanent pasture. It furnishes a full yield in the second year, dries quickly for hay, retains and yields a copious supply of seed, and affords a greater amount of nutriment when its seeds are ripe than it does in the flowering stage. The plant is a native of Europe (common in Britain), W. Asia, and N. Africa. It was introduced into America by Mr. Timothy Hanson, from whom it received its name. Its other name of 'cat's-tail' grass alludes to its cylindrical spike. There are nine other species of *Phleum* (three British), but none are cultivated.

Timur' ('iron'), called also **Timur-Beg** and **Timur-Lenk** from his supposed lameness, and by Western writers from a corruption of the last, **Tamerlane,** was the son of Teragay, chief of the tribe of Barlas, and was born at Kesh, near Samarcand, April 8, 1336. His most illustrious ancestor was Karachar Nevyan, minister of Jagatai, the son of Genghis Khan, but he was connected by the female line with the imperial stem, while his ninth male ancestor was the brother of the fourth ancestor of Genghis. In his twentieth year T. attached himself to the powerful Amir Kurgan, who gave him his grand-daughter in marriage. In 1358 he led a troop of 1000 horse under the Amir against Khorasan, and was left in possession of Herat. The murder of the Amir recalled him to Samarcand, where he was successful in persuading the turbulent chiefs to submit to Tugluk Timur Khan. Left by the latter as his viceroy over the whole country, he strove to reduce the unruly chiefs to submission, but having incurred the suspicions of Tugluk Timur Khan, he was obliged to fly with his brother-in-law, Amir Husain, to the deserts of Khuwarizm or Khiva. Soon, however, with a force of 12 horsemen, which quickly grew to 100, he left the deserts and raised the standard of royalty. In 1362 at the head of 1000 horsemen he entered Sistan, but was severely wounded and obliged to retreat. In the following year his army had grown to 6000 men, and he hastened to give battle to Alyus Khawajah, son of Tugluk Timur, whose army numbered 30,000 horsemen. T. gained a brilliant victory, and drove the invaders out of the country. In 1364 he inflicted upon the Jetes a second terrible defeat, and after defeating and driving from the country his envious brother-in-law Amir Husain, in 1369 settled at Samarcand in an uncontested throne. His first act was to call a *Kurultai*, or general meeting of chiefs, at which he settled the form of government, and rigorously organised his army. His ambition now turned to wider conquests. For some years he confined his operations to incursions into Khuwarizm, but in 1376 he crossed the Jaxartes and established Tokatmish on the throne of Kipchak, and in 1378 he crossed the Oxus and crushed Yusuf, the ruler of Khuwarizm. He next turned to Persia, and reduced the whole country to a province of his empire between 1380 and 1387. In 1390 the rebellion of Tokatmish called him to Kipchak, and after wintering at Tashkend, he crossed the deserts N. of the Caspian Sea, and on May 1391 inflicted a crushing defeat on Tokatmish in N. lat. 53°. In May 1392 he again entered Persia, and during the next five years thoroughly subdued the whole country. In 1393 he crushed Ahmed, Sultan of Bagdad, in 1394 conquered Georgia, and after stamping out a second rebellion of Tokatmish, crossed into Muscovy, and penetrated to the shores of the Dnieper. In 1396 he returned to Samarcand. The next project of his ambitious mind was the conquest of Hindustan, and in March 1398, at the head of 60,000 men, he passed through the defiles of the Hindu Kush, crossed the Indus, and in January 1399 defeated the army of the Sultan of Delhi on the banks of the Jumna. Soon after he took Delhi and Muttra, and gave over their inhabitants to indiscriminate massacre. In April 1399 he returned to his capital, carrying 'spoils beyond measure.' He next overran Syria, took Haleb, Damascus, Aleppo, and Bagdad, signalising his conquests by fearful massacres. At Angora, July 20, 1402, he completely defeated the great Ottoman Sultan Bajazet (q. v.), who was taken prisoner. T. now overran the whole of Asia Minor, and after quelling an insurrection in Persia returned to Samarcand. He now prepared for his long-meditated conquest of China, and in the depth of winter left his capital at the head of his army, crossed the Jaxartes on the ice, but was attacked at Ozar by fever and ague, and died there, February 17, 1405, leaving thirty-six male descendants. A great part of his immense empire was lost soon after his death, but his descendants reigned for a century in Jagatai and Persia, and for 300 years over Northern India, under the name of the Great Moguls. See the Persian history by Sheref-ed-Din-Ali (translated by Pétit de la Croix under the title *Histoire de Timur-Bec, connu sous le nom du Grand Tamerlane*, Par. 1722). A very unfavourable picture is given by the Syrian writer Ahmed ibn Arabshah. See Clavijo, the Ambassador of Henry III. of Castile at the court of T., *Historia del gran Tamerlan, e Itinerario* (translated by C. R. Markham for the Hakluyt Society, 1860); Gibbon's *Decline and Fall of the Roman Empire;* C. R. Markham's *History of Persia* (Lond. 1874); and Howorth's *History of the Mongols* (2 vols. Lond. 1876). Two works are extant, attributed to T.,—the *Institutes*, in Persian (Eng. translation, Oxford 1783), and the *Memoirs*, in the Turki language (Eng. trans. by Major Stewart, 1830).

Tin (*stannum*, symbol *sn*) is a metal belonging to the group which, in combination with oxygen, form acids. T. is a beautiful white metal having an atomic weight equal to 118; its specific gravity is 7·292, and its melting point is 442° F. It forms two series of compounds, dyad as in stannous chloride $SnCl_2$, and tetrad in stannic salts as stannic chloride $SnCl_4$. T. possesses a brilliant metallic lustre, is very malleable, but it is deficient in tenacity. When bent, metallic T. gives out a peculiar crackling sound, and on handling it emits a peculiar smell. When heated in the air a film of oxide forms on its surface, and at a white heat it burns with a brilliant white flame yielding stannous oxide. It is slowly dissolved by dilute hydrochloric acid, but in concentrated acid aided by heat it is rapidly changed into stannous chloride with evolution of hydrogen. Strong nitric acid does not affect the metal, but in a diluted condition the acid attacks it with violence, forming metastannic acid, a hydrated stannous oxide. The alkalies act upon T., at high temperature forming soluble metastannates, and further under the influence of heat it combines readily with chlorine, bromine, sulphur, and phosphorus. T. has a singular tendency to crystallise superficially when acted on by hot dilute aqua regia, a fact taken advantage of to form Moirée Metallique (q. v.). A number of the compounds formed by T. possess considerable economic value. The dioxide SnO_2 combines with water in two modified forms, viz., metastannic acid $H_2Sn_5O_{11}4H_2O$ and stannic acid H_2SnO_3. The former of these is the condition in which the metal is found in its ore tinstone; and, artificially prepared, it constitutes putty powder used for polishing plate, fine metals, and glass; and it produces the opaque glassy compound used as enamels. In combination with sodium, stannic oxide forms 'stannate of soda,' a salt much used in dyeing and calico-printing. A solution of this salt readily tins copper. Stannous chloride $SnCl_2$ in its hydrated form $SnCl_2 2H_2O$ is formed by dissolving T. in hydrochloric acid. It crystallises in the form of prismatic needles, and is a powerful reducing or deoxidising agent. Under the name of T. salts or T. crystals it is in extensive use as a mordant in dyeing and calico printing. Solutions of this salt are known in commerce as single and double muriates of T. according to their strength. Stannic chloride $SnCl_4$, a colourless mobile liquid which gives off dense white fumes, is prepared by passing dry chlorine gas over melted tin, or by treating corrosive sublimate with tin filings. When mixed with water a crystalline hydrate is formed, $SnCl_4 5H_2O$, with great evolution of heat. In its impure state the salt is used by dyers under the name of nitromuriate of T. or 'composition.' 'Pink salts,' also extensively used by dyers, is a double salt of chloride of T. and ammonium, $2H_4NCl, SnCl_4$. Stannic sulphide SnS_2, or Mosaic gold, is prepared by acting on T. filings with ammonium chloride, or mercuric chloride. It is obtained in crystalline scales of a golden yellow colour and a metallic lustre, and is used for imitating gilding and bronzing; but its use is now almost superseded by the employment of bronze powders.

Metallurgy of T.—T. is a metal which has been known and highly valued from very remote times, and in all probability it was used in the alloy bronze for an indefinite period before it was known in its separate condition. It was an important object in the commerce of the ancient Phœnicians, who brought it over both from the E. and from the S. of England; and among the Greeks it was distinguished as *Kassiteros*. From its external resemblance to lead it was termed by the Romans *plumbum album*, lead being called *plumbum nigrum*. For at least 2000 years the S.W. coast of England has been a famous source of T., the principal supplies of the world during that period having been drawn from that region which in consequence was called the Cassiterides or T. Islands, a name which has been erroneously associated with the Scilly Islands.

The only commercial ore of T. is tinstone, an impure dioxide of T.; its other compound, stannine, the sulphide of T., being found in insufficient quantity for use. Tinstone has not been discovered in great abundance in many localities, its sources hitherto having been Cornwall and Devonshire in England, Bohemia and Saxony on the continent of Europe, the islets of Banca and Billeton, and the Straits Settlements in Asia; and recently it has been discovered in great abundance in Tasmania, Queensland, and New South Wales. The tinstone in England is obtained partly as 'stream ore' from the alluvial deposits in valleys and the foreshores of the sea, and partly from lodes in T. mines. Stream T. is obtained in small particles, and is usually remarkably fine, so that certain of the preliminary operations of dressing and calcining necessary for the common ores can be dispensed with. The greater part, however, of the tinstone operated on is associated with various impurities, principally arsenical and sulphurous compounds. The preliminary operations to which T. is subjected are partly mechanical and partly chemical. The ore is first broken into small pieces and pounded very fine in a stamping-mill, and freed from the intermixed earthy gangre and all lighter impurities by repeated washing. It is next placed on the bed of a reverberatory furnace, where it is roasted in contact with air, the charge being frequently stirred to promote the oxidation of the sulphur and arsenical compounds present. Special forms of calcining apparatus, as Brunton's calciner and Oxland & Hocking's calciner, have been devised for effecting this operation. The roasted ore is again washed, whereby the soluble arsenical and sulphurous compounds are separated, and the oxides lighter than the T. oxide are floated away; the residue, consisting of 'black T.,' being ready for the operation of smelting. Two forms of furnace are used for smelting the prepared ore, one being of the ordinary reverberatory type, with a hollow bed, and the other being a shaft furnace on the principle of the blast furnace used for smelting iron, but built only to a height of from 7 to 10 feet. The reverberatory form is now exclusively used in England. The furnace charge is mixed with about one-fifth of its weight of small coal, a small proportion of slaked lime, and some fluor spar, a little common salt being sometimes added. After about five hours' exposure to a sufficient heat, the smelting process is complete; the mass is then rubbed to separate the slag which is drawn out through a special opening, and the metal with some liquid slag is run into one of a pair of basins, where the slag is skimmed off. The smelting T. is still impure, and requires to undergo a process of refining to free it from iron, arsenic, and other contaminations. It is therefore again placed in the reverberatory furnace, which is gradually heated till the pure fusible T. melts, leaving the pure refractory impurities, and the T. run into a basin is kept liquid by the heat of a fire for several hours, during which time it is 'poled' or stirred with a green stick, the dross rising to the surface being meantime skimmed off. Another method of refining is to lift the metal in ladles and pour it back into the basin from some height. When the formation of dross ceases the purified T. is cast into moulds.

T. has hitherto been the most valuable of the non-precious metals, but the abundance of the ore in Australia appears to have made such an impression on the price of the metal that copper and T. are at present about equal in value. In 1872 the average price of T. was £152, 10s., and in 1877 it had fallen to less than one half, £73, 3s. 6d. The quantity of British T. smelted in the former year was 9560 tons, valued at £1,459,990; and in 1877, 9500 tons smelted were valued at £695,162. Further in the year 1877 the imports of T. amounted to 13,762 tons, worth £961,330. The British T. exported in 1877 was equal to 6110 tons, of a value of £449,655; and of foreign T. 3894 tons, valued at £276,592, were sent abroad.

T. is much more extensively used in combination with other metals than in its pure condition; but for various purposes in chemical and pharmaceutical manufactures it is employed on account of not being injuriously acted on as are some other metals. Pipes of block T. are used for conveying water in some cases, but these pipes are more frequently only internally lined with pure T. T. pipes are also used for the worms of distilling apparatus, aerated-water machines, &c. Tinfoil consists either of pure T. or the metal alloyed with a little lead, beaten and rolled into thin sheets, and used for wrapping up food substances, &c. In thicker sheets the same material is used for bottle capsules, &c., and recently a considerable demand has arisen for sheet T. in connection with the phonograph. Tinfoil is also used for silvering mirrors by forming with it a mercuric amalgam. *Pewter* (q. v.) is an alloy of T. and lead in extensive use, and *Britannia Metal* (q. v.) consists principally of T., as does also *Queen's Metal* (q. v.). *Plumber's Solder* is a varying compound of T. and lead. Of greater importance are the alloys of copper and T., comprising *Speculum Metal*, containing 2 parts of copper and one of T., used for the mirrors of reflecting telescopes; *Bell Metal*, containing copper 78 and T. 22; *Gun Metal*, with about 90 copper and 10 T., largely used for machinery bearings, and *Bronze* (q. v.). See TINNING AND TIN-PLATE.

Tin'amou (*Tinamotis*), an aberrant group of *Rasorial* or *Gallinaceous* birds, occurring in S. America. They have a very short, even rudimentary tail. The elegant T. (*T. elegans*), the familiar species, attains the size of a large grouse. The neck is long, and the colour is a greyish buff on the head and neck, the head being crested, while the back is of a buff and blackish brown. The bird feeds on grain-seeds. It is easily captured.

Tin'cal. See BORAX.

Tinc'ture. See HERALDRY.

Tinc'tures are alcoholic solutions of medicines prepared from the crude drug by dissolving non-volatile principles. They are prepared by maceration or displacement, in some of them strong alcohol being used, and in others dilute. The process is described in article *Percolation* (q. v.). Most of the T. are made with proof spirit, which is composed of 5 parts of rectified spirit mixed with 3 parts of water, the resulting compound containing about 47·5 per cent. of water, the specific gravity being ·920. Ether is occasionally used, and ammonia is sometimes conjoined with the spirit, the former compound being called an ethereal tincture and the latter an ammoniated tincture.

Tin'dal, Matthew, one of the English Deists, was born in Devonshire in 1656. He studied at Lincoln and Exeter Colleges, Oxford, graduated B.A. in 1676, and was elected Fellow of All Souls in 1678. In opinions he was first High Church, then Roman Catholic (1685); next Low Church, and finally Rationalist. He died 16th August 1733. T.'s chief work, *Christianity as Old as the Creation, or the Gospel a Republication of the Religion of Nature*, was published anonymously in 1730, when the author was an old man. The argument of the book is that Christianity, as far as it is true, must be the religion of nature; for as God is unchangeable, so is human nature. Thus everything of value in any religious system is already given us outside of that system. T. attacks many of the statements in Scripture, especially those bearing on Jewish history in the ordinary rationalistic manner; but he does not explicitly deny the truth of the Christian revelation, though all his arguments tend to show that it is superfluous. Answers and refutations were numerous. Of T.'s other works the following are the most important:—*Four Discourses of Obedience to the Supreme Powers* (1694); *Rights of the Christian Church Asserted* (1706); *New High Church turned Old Presbyterian* (1709); *A High Church Catechism* (1710). T.'s style is often heavy and confused, but he was a man of learning, candour, and sense. See Lechler's *Geschichte des Englischen Deismus* (Stuttg. 1841); Hunt's *Religious Thought in England* (vol. ii. Lond. 1871); and Stephen's *English Thought* (vol. i. Lond. 1876).

Tin'der, an inflammable substance composed of partially-burned linen, or anything easily kindled. It is used for catching a spark produced by means of a piece of flint and steel. German T. or Amadou is made from several species of fungi (*Polyporus*). The soft tissue is sliced, beaten with mallets, and then dipped in solution of saltpetre.

Tin'ea is the generic term given to parasitic diseases of the skin of vegetable origin, the more important varieties being *T. tonsurans*, *T. decalvens*, *T. favosa*, *T. sycosis*, and *chloasma* or *pityriasis versicolor*. *T. tonsurans* has been described under Ringworm (q. v.). *T. decalvens* may affect the beard, scalp, and eyebrows, and appears as smooth bald patches of a circular form. Its parasitic character is doubted by some authorities, who ascribe it to some inflammatory influence which destroys the hair papillæ; and accordingly the disease is generally classed in this country as *Alopecia* (q. v.). *T. favosa* is described under *Favus* (q. v.), *T. sycosis* under *Sycosis* (q. v.), and *chloasma* under *Pityriasis* (q. v.).

Tin'ea, a genus of moths, including the familiar clothes moths, distinguished by having a rough head, with 5-jointed maxillary palpi and cylindrical labial palpi. The front wings are oblong-ovate and the hind wings ovate and scaly.

Tin'gi, a Brazilian name for the leaves of *Magonia glabrata* and *M. pubescens*, two medium-sized gregarious trees of the natural order *Sapindaceæ* (q. v.). The seeds of the fruit yield a sort of soap. An infusion of the root is used for stupefying fish, and the bark is applied to ulcers and sting-sores.

Tink'ar's Root is the root of *Triosteum perfoliatum*, a shrubby plant belonging to the honeysuckle family. It is a native of rocky woods in the United States from New York to Carolina, where it is called 'fever-root' from its medicinal application, or T. R. from the practitioner who brought it into notice.

Tinnevell'y, the chief town of the district of the same name in the Madras Presidency, British India, 50 miles N. from Cape Comorin, and 513 miles S.W. of Madras by rail; pop. (1871) 21,044. It almost adjoins the military station of Palamcottah. The *district* of T., the most S. in the peninsula, has an area of 5176 sq. miles; pop. (1871) 1,693,959. About 100,000 are native Christians, of whom the Roman Catholics live in fishing villages along the coast, while the Protestants are collected in towns. The crops are rice, cotton, and tobacco; the manufactures, jaggery sugar from the date palm, cotton cloth and muslin. The chief port is Tuticorin. The total exports are valued at £848,000; the imports at £439,000.

Tinn'ing, a process to which many small objects of brass, &c. —notably pins, hooks and eyes, and buttons—are subjected, whereby they receive a very thin coating of tin, which gives them a bright silvery appearance and untarnishable lustre. It is effected by boiling the objects a few minutes with granulated tin in a solution containing 1 part of cream of tartar, 2 of alum, and 2 of common salt in 12 of water. On the withdrawal of the tinned articles, they are dried in revolving barrels containing bran. Copper vessels are tinned by first thoroughly cleaning the surface to be operated on, heating it to a high temperature, while it is preserved from oxidation by a thin coating of rosin and pouring melted tin on it. The tin is uniformly spread over the surface, and the superfluous metal removed by the workman, who uses tow for this purpose. See TIN-PLATE.

Tinn'itus Au'rium is the Latin medical term for 'ringing in the ears.' It may be induced by a full dose of quinine. Nervous deafness is often accompanied by distressing T. A., and in such cases the hydrochlorate of ammonia may be given in full doses. In most cases it is an unimportant symptom, depending on some local temporary cause.

Tin'o, or **Tin'os** (anc. *Tenos*), an island of Greece, nomarchy of the Cyclades, immediately S.E. of Andros. Area, 81 sq. miles; pop. (1870) 11,022. It is 18 miles long by 8 broad, and is traversed by high mountains, the terraced slopes of which yield wine, wheat, melons, figs, &c. Marble, in block or wrought into various kinds of vessels and ornaments, and silk, raw or made into gloves and stockings, are the chief exports. The chief town, T., on the S. coast, is the seat of a Roman Catholic bishop, and has two Roman churches, a small harbour, and a pop. of 2028. To the N. of it is the white marble church of Panagia Evangelistria, a famous resort of pilgrims.

Tin-Plate consists of sheets of fine charcoal iron-coated and partially alloyed with pure tin with the view of preserving the iron from oxidation and giving it a clean, bright, and not easily tarnished surface. As is well known, T.-P. is in most extensive use for common mugs, basins, pitchers, tea and coffee pots, lamps, candlesticks, and for innumerable other purposes; but recently the demand for the preparation has enormously increased owing to the development of the trade in 'tinned' meats, fruits, and provisions of all kinds. In preparing T.-P. the sheets of iron must first be made chemically clean with the most scrupulous care. To secure this they are first pickled in dilute sulphuric acid, then heated to redness in a reverberatory furnace. On cooling they are passed between polished rollers, immersed in a sour mixture of bran and water, from which they are passed into a dilute mixture of sulphuric and hydrochloric acids. Thereafter they are scoured with bran and plunged into either pure water or lime-water. Being now cleaned, they are placed for about an hour in a bath of pure melted tallow, and from that they are passed into the molten tin, the surface of which is kept from oxidation by a thick layer of tallow. After about an hour and a-half they are withdrawn, and the superfluous tin allowed to drain off. They are then once more immersed in a tin bath, and next plunged into hot molten tallow, which carries all the superfluous tin to the lower edge of the plates, after trimming which the plate is finished. Plates coated with a varying alloy of tin and lead are known as Terne plates. These are extensively used for structural purposes, but they cannot be safely employed

in connection with food substances. In 1877 there were 75 T.-P. works in the United Kingdom, the greater part of them being in Wales, the estimated quantity of plates made in that year being 4,049,750 boxes, which would weigh about 197,750 tons. The greater part of the exports of T.-P. go to the United States and Canada.

Tin'tern Abbey, Monmouthshire, standing on the Wye's right bank, 5 miles to the N. of Chepstow, was founded for Cistercian monks in 1131 by Walter, second son of Richard Fitz-Gilbert de Clare. Rebuilt by Roger de Bigod (1269–88), it is an excellent example of the Transition style from Early English to Decorated, the most striking features of its cruciform church (228 by 150 feet) being the central belfry arches, and four great windows with their lacelike tracery. The dismantling of the abbey followed close on the dissolution (1337), when the ruins were granted to the ancestor of the Dukes of Beaufort.

Tintorett'o, Il, one of the greatest painters of the Venetian school, whose real name was Jacopo Robusti, and who received his well-known surname from the fact of his father being a dyer (*Tintore*), was born at Venice in 1512. He studied for a few days under Titian, but deserted the studio of the master for some unknown reason, and subsequently became a devoted student of antique sculpture, of anatomy, and of the works of Michael Angelo. On the walls of his studio he inscribed the ambitious motto, *Il disegno di Michelangelo ed il colori di Tiziano*, and such was the ardour and rapidity of his labour, reflected in the intensity of his style, that he acquired the nickname of Il Furioso. It was admitted by Sebastian del Piombo that T. could paint as much in two days as he could in as many years. The palaces and churches of Venice were rapidly adorned by him with vivid representations of historical, mythological, and scriptural subjects, but only a few of his frescoes survive. The only works said to bear his name are 'The Crucifixion,' in the Scula di San Rocco (engraved by Agostino Caracci), the 'Miracle of the Slave' in the Academy, and the 'Marriage of Cana' in the Church of Santa Maria della Salute. His largest work, 'Paradise,' on the ceiling of the library in the Doge's palace, is 84½ feet by 34, and contains upwards of 100 figures. Other famous works are 'Belshazzer's Feast,' the 'Tiburtine Sibyl,' 'Last Supper,' 'Worship of the Golden Calf,' 'Last Judgment,' and 'Slaughter of the Innocents.' About a third of his works are symbolical, and he frequently makes ingenious use of the winged lion of St. Mark. He certainly belongs to the greatest class of painters in the sense that he is neither ideal nor atrabiliar, but intensely faithful in his treatment of nature. His genuine love of brilliant colour he somewhat sacrificed to an overweening estimate of the value of chiaroscuro, which latterly made him pronounce 'black and white' the finest of all colours. The vehemence of his execution has given rise to the objection that his art lacks refinement, but, as Ruskin remarks, the stroke of T., in the eyes of the ignorant a mere violent dash of colour, is, though the work of an instant, modulated to the utmost degree of delicacy. Daring and passionate in imagination, T. sought to vary by dramatic movement the romantic motives of the Venetian school, and brought to perfection the poetry of chiaroscuro with something of Angelo's sublimity. T. died at Venice, 31st May 1594. His favourite daughter, Marietta, who was an excellent portrait-painter, died in 1590, but his son Domenico, also a painter, lived till 1637. See Crowe and Cavalcaselle, *History of Painting in Italy* (Lond. 1864); and Ruskin, *The Relation between Michael Angelo and Tintoret* (1872).

Tippecanoe', a river of Indiana, U.S., which rises in the T. lake and winds S.W. for 200 miles to the Wabash. At Battle Ground on this river General Harrison defeated the Indians under the 'Prophet,' brother of Tecumseh (5th November 1811).

Tipperah (*Tripura*), the name of a British district and also of a native state in political connection with Bengal, on the N.E. frontier of India. The *district* of T., which lies between the hills and the Meghna river, has an area of 2655 sq. miles; pop. (1872) 1,533,931. It is a flat plain, intersected with numerous water-courses; and produces abundant crops of rice, jute, and betel-nuts. In 1876–77 the registered exports were valued at £606,000, and included rice, jute, and betel-nuts; the imports at £170,000, chiefly piece-goods and salt. There are manufactures of weaving, pottery, and mats. The chief town is Comillah.—The *state* of T., which lies E. among the hills, has an approximate area of 3876 sq. miles; estimated pop. 74,242; revenue, £70,000, inclusive of £51,406 derived from estates in British territory. It is the possession of these estates that decides the succession to the throne. The products are rice, cotton, timber, and elephants. The capital is Agartala. The present Rajah is an enlightened man, an amateur photographer, and a student of physical science. A British political agent has resided at his court since 1871.

Tippera'ry, a county of Ireland, province of Munster, surrounded by King's County, Queen's County, Kilkenny, Waterford, Cork, Limerick, Clare, and Galway. Area 1,061,730 acres; pop. (1871) 216,713. T. lies in the basin of the Suir, which rises in the N. of the county and forms part of the southern boundary before passing through Waterford to the sea. The surface, for the most part level, is diversified by hill-ranges, of which the chief are the Galtees (3015 feet), Knockmeledown (2150 feet), Slievenaman (2364 feet), the Devil's Bit (1600 feet), the Keeper (2278 feet), and Slievenamuck (1215 feet). The Shannon and Lough Derg form part of the western boundary, separating T. from Galway and Clare; and other streams which water it are the Brosna, Nenagh, and Mulkear. There are many small lakes, and among the more fertile districts are the plain of Ormond and Golden Vale. The prevailing rocks are clay, slate, greywacke, sandstone, and limestone; and among the minerals are anthracite, coal, copper, zinc, and lead mixed with silver. The soil, calcareous loam, is in parts singularly productive. In 1876 there were 135,942 acres under crops, 305,758 under grass, 16,363 in woods, and 78,402 in bog, waste, and water. The crops include potatoes, oats, wheat, turnips, and mangel-wurzel. T. had (1876) 13,484 horses, 6938 asses, 132,876 cattle, 127,046 sheep, and 52,929 pigs. In 1874 the valuation amounted to £398,357. Divided for civil purposes into a N. and S. Riding, T. returns two members to Parliament. Clonmel (q. v.) is the chief town. There are numerous antiquities, including the Holy Cross Abbey at Cashel, and Cahir Castle. The Mitchellstown caves, on the border of Cork, are of great extent and contain fine stalactite deposits. The pop. has been reduced, chiefly by emigration, to the extent of 114,854 since 1851.

Tippera'ry (Ir. Gael. *Tiobrad-Arann*, 'the well of the district of Ara'), a market-town in the county of the same name, on the Arra, an affluent of the Suir, 24½ miles N.W. of Clonmel and 110 S.W. of Dublin by the Great Southern and Western railway. Lying at the base of the Slievenamuck mountains, near the centre of the Golden Vale, on the direct road from Clonmel to Limerick, it carries on a considerable trade in butter, corn, flour, &c. The daily butter-market is said to be next in importance to that of Cork. T. is the headquarters of the Union Agricultural Society, and has a spacious corn and provision market, in which markets are held on Thursdays and Saturdays. There is a fine parish church, a Gothic Roman Catholic church with a spire 156 feet high, a Presbyterian church, a Methodist chapel, a town-hall, &c. Pop. (1871) 6084.

Tipp'oo Sul'tan ('tiger-king'), the son of Hyder Ali, and the most inveterate enemy that the English ever encountered in India. Born in 1750, he displayed a predilection for arms from his youth, and during his father's lifetime twice defeated British officers. In 1782 he succeeded to the throne of Mysore. He found himself at the head of a veteran army of 100,000 men, with three millions sterling in his treasury; and he brought to a not inglorious conclusion the war then raging with the British by the treaty of Mangalore in 1783. A second war lasted from 1790 to 1793, and a third broke out in March 1799, partly instigated by French Republican emissaries, who planted a tree of liberty at Seringapatam, and hailed the Sultan as Citizen T. Within two months, T. was driven from the field into his fortress of Seringapatam, which was stormed by the British. T. fell in the assault, and was buried on the 5th of May in his father's mausoleum. T. did not inherit the military and political genius of Hyder, and he appears to have become intoxicated by the exercise of despotic power. He behaved with great cruelty to his prisoners; struck coins with his own name as 'padishah;' and forcibly converted to Islam the Hindu population of the Malabar coast. His favourite plaything—a tiger, in life size, wound up to growl and tear an Englishman—may now be seen in the Indian Museum. See *The History of T. S., written by Mir Hussain Ali Khan* (translated into English by Colonel Miles, Lond. 1844).

Tip'ula. See CRANE-FLY.

Tirabosch'i, Girolamo, a learned Italian writer, was born at Bergamo 28th December 1731. He entered the Society of Jesus, became professor of eloquence in the University of Milan, was appointed in 1770 head librarian to Francis III., Duke of Modena, obtained the title of knight and councillor in 1780, and died at Modena 3d June 1794. His principal work, *Storia della Letteratura Italiana* (Mod. 1772-82, 13 vols.; Rome 1785, 12 vols.; Milan 1822-26, 16 vols.), is one of the great authorities on Italian literature to the close of the 18th c. A French abridgment was published by Landi (Bern 1784, 5 vols.), and a German abridgment by Jagemann (Leip. 1777-81, 6 vols.). He also wrote *Vetera Humiliatorum Monumenta* (Mil. 6 vols. 1793), *Biblioteca Modenese* (6 vols. 1781-86), *Memorie Storiche Modenesi* (6 vols. 1793); and 43 vols. of a *Giornale de' Letterati* appeared under his editorship.

Tirailleurs (Fr.), skirmishers or sharpshooters. The name does not occur in the French army before the year 1792. It was given to certain bodies of French marksmen during the first campaigns of the revolutionary war, whose business was to annoy the front of an advancing or the rear of a retreating enemy.

Tiree' (Gael. *Tir-ith*, 'land of corn'), an island of the Hebrides, 18 miles N.W. of Iona, and 2 S.W. of Coll, is 12 miles long by 4 broad, has a flat surface, but is surrounded by rocky bays. It abounds in game and rabbits, and the caves of the Ceanmharra cliffs are the haunt of myriads of seafowl. The inhabitants, who numbered 2834 in 1871, are engaged in cattle-rearing and fishing. The Duke of Argyll is sole proprietor. Throughout T. are scattered many Scandinavian forts, standing stones, and other remains.

Tire'sias, a celebrated soothsayer, a native of Thebes, who was struck blind either by Athena because he had seen her bathing, or by Hera, through resentment at his having, in a dispute between her and Zeus, decided in favour of the latter. In compensation, however, he was granted the divine gift of prophecy, and his life was prolonged for several generations. In the war of the Seven against Thebes he declared that Thebes would be victorious if Menœceus would sacrifice himself; and during the war of the Epigoni, on the defeat of the Thebans, he advised them to commence negotiations for peace in order to gain time for flight. During the flight T. died, after having drunk from the well of Tilphossa.

Tirhut', a district in N. Behar, Bengal, British India, the largest and most populous in the province. It lies between the Ganges and the Himalayas, and is crossed by many minor rivers. Area, 6343 sq. miles; pop. (1872) 4,384,706. T. is purely agricultural. The crops are rice, barley, Indian corn, and inferior cereals, indigo, opium, and tobacco. The indigo made here is the best in India. There are about 42 concerns, with an annual out-turn of nearly 1000 tons. Saltpetre is manufactured to some extent. A large trade is carried on by boats with Patna, and by land with Nepal. In 1876-77 the registered exports were valued at £1,113,000, including indigo, oilseeds, saltpetre, and tobacco; the imports at £926,000, consisting chiefly of piece-goods, food-grains, and salt. The scarcity of 1873-74 was very severely felt in T. Since 1875 T. has been divided into the two districts of Durbhungah and Muzufferpur.

Tirle'mont (Flem. *Thienen*), a town of Belgium, province of Brabant, on the Great Geete, 12 miles E.S.E. of Louvain by rail. Its church of St. Germain, on an eminence over the town, dates from the 9th c., and contains an altar-piece by Wappes. T. manufactures flannel, woollen hosiery, leather, sugar, and oil, and has a large trade in corn and wool. Pop. (1877) 13,206. It was the scene of a defeat of the Austrians by Dumouriez, March 16, 1793. See Wauters, *L'Histoire des Communes Rurales de T.* (1876).

Tir'nova (Turk. *Turnov*), a fortified town of Bulgaria, on the Jantra, a tributary of the Danube, 35 miles S.S.E. of Sistova and 65 miles N.W. of Jamboli by rail. It stands on a hill 1000 feet high, and is encircled by a wall and trench. Formerly the capital of Bulgaria, it is still the commercial centre of the state, and the converging point of several of the Balkan routes. It is the seat of a bishop, and has several Greek churches, besides mosques, baths, and bazaars. The chief industries are the making of silk and coarse cloth and dyeing. Pop. 13,000. During the Russo-Turkish war the central division of the Russian army, under the Grand Duke Michael, met with no opposition on entering T. (6th July 1877), and there the Czar issued a proclamation to the Bulgarians whom he had come to liberate. T. formed the base of General Gourko while holding the Shipka Pass against Suleiman Pasha, and in the peace negotiations subsequent to the war was made the Bulgarian headquarters by General Todleben. The Assembly of Notables met at T. to elect a prince for the newly-liberated Bulgaria, 2d February 1879. See Kanitz, *Tirnovo's alt-Bulgarische Baudenkmale* (Vienna 1876).

Tir'yns, one of the oldest of the Hellenic cities, noted in the *Iliad* as the 'well walled,' situated in Argolis, in the Peloponnesus, 1½ miles N. of Nauplia, around a rock 50 feet high, on which stood the Acropolis, part of whose 'cyclopean' walls, of huge, irregular, polygonal blocks of stone, is still standing. Excavations were carried on at T. by Schliemann in 1876.

Tisane, or **Ptisan** (Gr. *ptisso*, 'I pound'), is an infusion or decoction, used as a weak diet drink, and is a favourite form for the administration of remedies in the domestic medicine of France.

Tisch'endorf, Lo'begott Friedrich Konstantin von, the great New Testament critic, was born January 18, 1815, at Lengenfeld, in the Saxon Voigtland, Germany. After studying theology and philosophy at Leipzig from 1834, he became a privat-docent there in 1839, and for some years after travelled over a great part of Europe and the East in search of materials for a revision of the text of the New Testament. After his return he was appointed extraordinary professor of theology at Leipzig (1845), and ordinary professor (1859). In 1853 and 1859 he undertook a second and third journey to the East, particularly to Egypt and Sinai, from which he brought back many valuable MSS., including a Greek Bible of the 4th c. He died December 7, 1874. T.'s works chiefly relate to textual criticism of the New Testament; editions of the *Codex Ephraëmi Syri* (Leip. 1843 and 1845), and of the *Codex Friderico-Augustanus* (Leip. 1846), *Monumenta Sacra Inedita* (1846; *nova collectio*, 6 vols. 1855-71), *Evangelium Palatinum Ineditum* (1847), *Codex Amiatinus* (1850 and 1854), *Acta Apostolorum Apocrypha* (1851), *Evangelia Apocrypha* (1853), *Apocalypses Apocryphæ* (1866), *Synopsis Evangelica* (3d ed. 1871), *Codex Claromontanus* (1852), *Fragmenta sacra Palimpsesta* (1854), *Codex Sinaiticus* (4 vols. St. Petersb. 1854; smaller ed. Leip. 1863), *Novum Testamentum Vaticanum* (Leips. 1867). His greatest works are the critical editions of the New Testament (8th ed. 2 vols. 1869-72; smaller ed., half in 1873, the remainder completed by C. R. Gregory, 1877), and of the Septuagint (5th ed. 2 vols. 1875). See Volbeding, *Konstantin T. in seiner 25 jährigen schriftstellerischen Wirksamkeit* (Leip. 1862).

Tiss'ues, the name given to the primary layers of which the bodies of animals and plants are composed. It consists of *cells*, *fibres*, *tubules*, &c., and these are frequently further elaborated and interwoven so as to produce a more complex form of tissue than in other cases. The elementary T. of the human body are represented by (1) *Epithelium* (q. v.), seen in the skin and the lining membrane of the digestive canal; (2) *Areolar*, *Cellular*, or *Connective tissue*, widely distributed in every part of the human frame, and serving to bind together and to consolidate other parts and tissues; (3) *Adipose tissue* or *fat*, composed of large cells, containing oily matter, and serving as a storehouse of combustible matter, a protective layer, and a conservator of heat; (4) *Pigmentary* tissues, seen in the *choroid coat* of the eye, in the *iris*, in the skin, &c; (5) *Cartilage* or *gristle*, of *permanent* nature (as in the *rib-cartilages*) or *temporary* nature, as in the fœtus, where it is destined to become bone; (6) *Bones* and *teeth*, which grow according to the general laws of tissue-growth.

Tiss'ues, Veg'etable. See CELLULAR TISSUE, VASCULAR TISSUE, and VEGETABLE PHYSIOLOGY.

Tit or **Tit'mouse** (*Parus*), a genus of Insessorial birds belonging to the order *Dentirostres*, and forming the type of the family *Paridæ*, in which the bill is straight and short, with the nostrils opening at its base. The wings are of moderate size, and the first 3 quills are graduated. The tail is rounded and even, and the tarsi are scaly in front. The inner toe is short, and the claws curved and strong. In the genus *Parus* itself the nostrils are concealed by the forehead plumes, and the 4th and 5th quills are the longest. The hinder claw and toe are extremely long. The Great T. (*Parus*

major) is a familiar inhabitant of Britain and Europe generally. It attains a length of 6 inches, and is of a purple-black colour on the top of the head and throat, with a spot of pure white on the nape of the neck. The back and shoulders are greenish black, and the under parts are light yellow. The nest is made in holes in walls and in trees. The Blue T. (*P. cæruleus*) is also a familiar British bird, of a bluish-grey colour above, and whitish yellow below; while the red-bellied T. (*P. rubidiventris*) and the yellow-cheeked T. (*P. xanthogenys*) are good examples of other species, the former occurring in S. India and the latter in the N.W. Himalayas. The *Parus caudatus* or long-tailed T. or 'bottle-crested T.' is a familiar British species, and builds a marvellously constructed little nest, of egg-shaped form. The average length is 5½ inches. The crested T. (*P. cristatus*) is of rare occurrence in England, but is common in N. Europe. Its length is 4½ inches, and its colours are black and white boldly disposed. The genus *Paroides* includes the *P. biarmicus* or bearded T., found rarely in England, but common in Holland. The upper parts are pale fawn and grey, while the under parts are white, tinted with yellow. The average length is 6 inches. The marsh T. is a well-known British form. The Cole T. (*Parus ater*), so-named from its dark-coloured plumage, is common in Britain.

Tita'nium (Ti = 50), a metallic element closely allied to tin, is obtained from certain ores, *rutile, anastase, brookite*, &c., in which it occurs in the form of titanic acid (T_2O_4). It is also found in combination with iron in *iron sand, iserine*, or *menachanite*. The acid is extracted by treating the ground mineral with carbonate of potash so that titanate of potash is formed; and this compound is then decomposed by a series of operations, the chief of which is treatment with hydrochloric acid. When pure it is white, but becomes yellow when strongly heated. It is employed in the manufacture of artificial teeth and for tinting glazed porcelain. Passing dry chlorine gas over a heated mixture of titanic acid and charcoal results in the formation of a colourless volatile liquid, tetrachloride of T. ($T_2 Cl_4$), which is very similar to the corresponding tin compound. From this compound metallic T. is obtained in prismatic crystals by passing its vapour over heated sodium. T. has a remarkable affinity for nitrogen; and the violet-coloured nitride (TiN_2) is formed when ammonia gas is passed over red-hot tetanic acid. The terchloride ($TiCl_3$) is obtained in violet crystals, and forms a violet solution in water which resembles stannous chloride as a reducing agent. Lower oxides are believed to exist.

Titanothe'rium, an extinct genus of *Mammalia*, the remains of which occur in Miocene deposits of N. America, and which is included by Marsh in the Ungulate family *Brontotheridæ*. These animals were large, had long skulls, small incisor teeth, and very large horn cores.

Ti'tans, in Greek mythology, were six sons and six daughters of Uranos and Gaia, named Okeanos, Koios, Kreios, Hyperion, Iapetos, and Kronos; Theia, Rhea, Themis, Mnēmosynē, Phoibō, and Tethys. Uranos having banished to Tartarus the Hekatoncheires ('the hundred-handed') and the Cyclōpes, Gaia called the T. to avenge their brothers. They rose and freed them, deposed Uranos, and set Kronos in his place. Kronos and the T. were in their turn put down by the sons of Kronos and Rhea, named the Olympioi, with Zeus at their head, but not till after a long struggle, in which Zeus brought to his aid the Cyclōpes and Hekatoncheires, whom Kronos had again imprisoned in Tartarus. Zeus quelled the T. with the lightning given him by the Cyclōpes, hurled them to Tartarus, placing them under the care of the Hekatoncheires. This struggle, called the *Titanomachia*, was regarded as symbolic of the conflict of reason and order with the rude forces of nature. See Preller, *Griechische Mythologie* (3d ed. by Plew, 2 vols. Berl. 1872–75).

Tithes (Old Eng. *teotha*, a 'tenth' part) are a tenth of the yearly produce of lands, arising from the crops which they bear and the stock which they maintain, and one-tenth of the clear profit of the industry of the people. The origin of T. is to be found in the legal provision made for the Levites in the Mosaic Law (see Levit. xxvii. and Deut. xiv.). The usage passed into the Christian church at an early date, and gradually received the sanction of external law. In England, T. of crops is called *prædial;* as of corn, fruit, &c. T. of stock is called *mixed;* as of wool, lambs, milk, &c. T. of industrial profit is called *personal*. The great T., as of corn and hay, are generally payable to the rector or parson; the small T. to the vicar. Mines and wild animals—deer, &c.—are not tithable, nor are fish taken in the sea or river; but if taken in enclosed water they are liable. Barren ground becomes liable if converted into pasture-land, after seven years from the first attempt to make it productive. Day-labourers are not liable to personal T., and the Queen is exempt by her prerogative. A vicar is not liable for T. to his rector, nor a rector to his vicar. Lands may be exempt from T. by *composition*, or by *custom*, or *prescription*. Composition is by agreement between the owner of the land and the parson or vicar, with consent of the ordinary and his patron, that the land shall for the future be free of T. for a stated equivalent or *Modus* (q. v.). The agreement, to be valid, must be equitable, and the equivalent invariable. A statute of Elizabeth limits the period of composition to twenty-one years, or three lives. A discharge, total or partial, by custom or prescription, is given when lands have been totally or partially exempt from Immemorial Time (q. v.). 6 and 7 Will. IV. c. 71, amended by subsequent statutes, provides for the conversion of all the uncommuted T. in England and Wales into a corn rent-charge, payable in money, according to the value of a fixed quantity of corn, as ascertained from year to year by the average price of corn for the seven years ending at the preceding Christmas. Commissioners are appointed for the purpose—two by a Secretary of State, and one by the Archbishop of Canterbury. Commutation may be (1) by parochial agreement, voluntary on the part of the majority of those having two-thirds of the interest in the land and T. It is binding on the minority unless an appeal be taken, to sustain which sufficient cause of objection must be shown. (2) It may be by compulsory award, which must be effected under the Central Board of Commissioners. 23 and 24 Vict. c. 93 extends the Acts for the Commutation of Tithes.

Ti'thing, a former subdivision, viz. tenth part, of the Hundred (q.v.), occupied by ten householders, each of whom was answerable for the good conduct of the others. Its limits were ordinarily co-extensive with those of a parish, with which it is now practically identical, just as the office of *T.-man* is merged in that of a petty constable.

Titho'nus, in the Greek myth resung by Tennyson, was a son of Laomedōn, who from enamoured Eōs obtained the boon of immortality, cruel because not coupled with immortal youth.

Ti'tian, or **Tizia'no, Vecell'i**, the greatest painter of the Venetian school, was born probably in 1477, of a family of local importance, at Pieve di Cadore, an upland village in the Friulian Alps, 86 miles from Venice. The Piave, flowing to Venice, the swelling outline of Monte Cridola, the 'dawn-coloured' peaks of the dolomites, all entered into the education of the future painter, who was almost the first to appreciate the beauty of landscape. Of T.'s early artistic aspirations very little is told even by way of fable, but at the age of eleven, along with his brother Francesco, he was despatched by his father to Venice, where he studied first under Zuccato, the mosaist, and then under Gentile and Gian Bellini. The influence of Palma and Giorgione is visible in such early works as the wonder-working Christ in the church of San Rocco, and the allegory 'Profane and Sacred Love' (now at Rome), which is characterised by loveliness and simplicity. In 1507–10 T. was employed with Giorgione in covering the Fondaco de' Tedeschi (the 'German cloth warehouse') with frescoes long since destroyed by the sea winds. After painting the famous 'Tribute Money,' he offered and was engaged in 1513 to adorn the Hall of Council with 'The Battle of Cadore,' of which, in addition to descriptions, we have now only a sketch and Fontana's solitary engraving. Meantime T. had been invited to Rome by Leo X., and although preferring to serve 'their sublimity' the Doge and Signori, his profitable dealings so hindered this battle-piece that he was rebuked for negligence in 1518, 1522, and 1537, its completion in the last year being due only to the rivalry of Pordenone. The 'broker's patent' for which he had stipulated he received in 1516; it was worth 100 ducats a year, and involved the duty of painting a portrait of the Doge. As his fame rose, T. became the courtly painter of courts, subservient in choice of theme, devoted equally to Venus and the Virgin, but asserting his independence characteristically in determining his rate of production, and in demanding his pay with pertinacity. Long a favourite at the courts of

Ferrara and Mantua, he was introduced in 1532 by Aretino, his life-long friend, to the Emperor Karl V., who, delighted by his portrait, loaded T. with high-sounding honours, and in 1541 bestowed on him a pension which was little else than a legacy of care. The subsequent events in his life are his triumphal descent on Rome in 1545-46, his visit to the imperial court at Augsburg in 1550-51, and his reception of a new royal patron in Henri III., who visited him in 1574, while returning from Poland to France. In 1523 he had married Cecilia, of whom little more is known than that she died in 1530. The beauty of his daughter Lavinia, and the industry of her artist brother Orazio, consoled T. for the profligacy of Pomponio, his elder son, who became a bishop, and shocked even Aretino by his vices. Wealth, power, and honour had fallen to T. long before he was stricken by the plague, on 27th August 1576. Among his masterpieces are 'Bacchus and Ariadne' (National Gallery), 'Peter Martyr' (destroyed by fire, 1867), 'St. Catharine,' 'Defeat of the Janizaries,' 'St. Sebastian,' 'Annunciation,' 'Christ in the Garden,' 'Medea and Jason,' 'Venus and Adonis,' 'Danäe,' and 'Noli me Tangere.' T. was a master of delicate, powerful portraiture. It was his portrait of Philip II. which won the heart of Mary Tudor. Ruskin ranks him as the principal painter of romantic landscape. The contemporary of Michael Angelo and Raphael, both of whom he long outlived, T. illustrates more perfectly than either the strength and weakness of the Renaissance. He broke completely away from the intensity of Florentine art and the mysticism of the Sienese, and turned to revel in the material grandeur which had reached its height in the pride of Venetian luxury. His style is large and sane, like his nature, and his art 'a golden mean of joy unbroken by brusque movement of the passions.' His was the vigour of exquisitely-balanced faculties; his, above all, the sublime sense of colour and the mastery of pure tints in subtle interplay. Each masterpiece is a chromatic symphony, aglow with the fires of Venetian sunset, luminous with the haze of the lagoons, shot through with 'the inmost purple spirit of light,' radiant with the pearly gleam of flesh, tremulous with silver lights and golden mysteries of shadow. 'There is,' says Ruskin, 'a strange undercurrent of everlasting murmur about his name, which means the deep consent of all great men that he is greater than they . . . that there is a softness more exquisite than Correggio's, a purity loftier than Leonardo's, a force mightier than Rembrandt's, a sanctity more solemn than Raphael's.' A statue of T. was erected at Pieve in 1877. See Gilbert's *Cadore, or T.'s Country* (Lond. 1869); Symonds' *Renaissance* (vol. iii. 1877); and especially *T., his Life and Times*, by Crowe and Cavalcaselle (2 vols. Lond. 1877).

Titica'ca, a remarkable lake, situated in the heart of the Andes, partly in Peru and partly in Bolivia, and 12,545 feet above the sea-level. It lies N.W. and S.E., and is 120 miles in length, with an average width of from 50 to 60 miles. The southern portion, measuring 24 by 21 miles, is almost severed from the main body of the lake by a projecting peninsula. The lake discharges at its S.W. extremity by the Desaguadero (q. v.) into the salt Lake Aullagas, which has no known outlet (see PERU). The E. shore of Lake T. is abrupt and mountainous, but the W. and S.W. shores are low and level, and are skirted by thick beds of tall rushes swarming with waterfowl, and of floating weed, which affords food to cattle when the scanty land-pastures are exhausted. The lake is deep and stormy, so that ice forms near the shores only. It contains a number of strange fishes, and eight species of marine crustaceans, which seem to indicate that it was once at the sea-level. There are eight habitable islands, the largest being T., which gave its name to the lake, and has an area of 20 sq. miles. It was the sacred island of the Incas, who laid it out in terraces planted with consecrated maize and flowers, and irrigated by channels supplied from the royal bath at the top. According to Squier, the name T. probably signifies 'Tiger Rock,' and is due to a fancied resemblance of the rugged crest of the island to a wild cat. The lake is now navigated by steamers, and may be reached by railway from the seaport of Mollendo, 346 miles distant.

Ti'tiens, or **Tiet'jens, Tere'sa**, one of the greatest of operatic singers, was of Hungarian extraction, and was born at Hamburg in 1834. She appeared as *Lucrezia* in her native town in her sixteenth year, and her subsequent engagements at Frankfurt and Vienna had established her position as the chief lyric artist in Germany before her debut in London on April 13, 1858, as 'Valentine' in *The Huguenots*. Her success here was so decided that she made this country her future home, and it was the peculiar scene of her triumphs. She followed Mr. Mapleson's fortunes at the Opera House in the Haymarket and at Drury Lane, and was the sheet-anchor of his management. Nature not only gifted her with a voice of marvellous strength and brilliant quality, but with a dramatic force illumined by the fire of genius. Her physique was imposing, and her style full of stately dignity. Her rare devotion to her art generated the perfection of her vocal method. Upon her alone fell the mantle of Grisi, and her *répertoire* embraced all the grandest tragic rôles in modern opera. As Norma, Donna Anna, Semiramide, Medea, and Leonora, she was unequalled by any of her contemporaries. In the concert-room and in oratorio her success was unequivocal. She died in the full maturity of her powers on October 3, 1877, leaving a blank on the stage well-nigh impossible to fill, while many friends, particularly among the poor and struggling class, mourned the loss of one beloved for her generosity, unselfishness, and warmth of heart. A monument was erected to her memory in All-Souls' Cemetery, Kensal Green, London, November 1878.

Tit'lark and **Tit'ling**. See PIPIT.

Ti'tle, Registra'tion of. See LAND, TRANSFER OF, BY REGISTRATION, LANDED ESTATES COURT.

Ti'tle-Deeds are the written evidences of the ownership to real estate. To pledge them in security of a pecuniary loan may in England create a Mortgage (q. v.). See also LAND, TRANSFER OF, BY REGISTRATION.

Tit'ular, one who possesses the title of an office without the real power or authority belonging to it; *e.g.*, the King of Sardinia was titular King of Jerusalem. Titular dignities of this kind are common in the Roman Catholic Church. Bishops may be nominally appointed over districts in which there are no Christians—*in partibus Infidelium* (q. v.). In English Ecclesiastical law a T. is one who may lawfully enjoy a benefice without performing its duties. In Scotch law the application of the term is different. At the Reformation, the Church lands having become the property of the crown, the king erected them into temporal lordships, the grantees to which were styled *Lords of Erection*, or *Titulars of the Tithes*.

Ti'tus, Epistle to. See TIMOTHY.

Ti'tus, Fla'vius Sabi'nus Vespasia'nus, Roman emperor, elder son of the Emperor Vespasian (q. v.) and Flavia Domatilla, was born December 30, 41 A.D. Brought up along with Britannicus at the imperial court, he early showed great bodily and mental vigour. He saw service first in Germany, and afterwards fought under his father in Britain. T. also accompanied his father in the expedition to Palestine in 67 to crush the rebellion of the Jews, and, on Vespasian's departure for Rome to receive the imperial dignity, was entrusted with the sole conduct of the war, which ended with the capture and destruction of Jerusalem, September 8, 70. After this T. was admitted to a share in the government, and received a triumph along with Vespasian. The licentiousness and cruelty he had previously shown were, on the death of his father in 79, when he became sole Emperor, succeeded by a mildness and clemency that won for him the title of '*amor et deliciæ generis humani.*' His wise beneficence mitigated the disasters of his reign—the eruption of Vesuvius, 24th August 79, which buried Herculaneum and Pompeii, a destructive plague, and a three days' and three nights' conflagration in Rome (80). The ruins of the public baths built by T. still exist. He died 13th September 81, after a reign of 2 years, 2 months, and 20 days, and was succeeded by his brother Domitian. See Beulé, *T. et sa Dynastie.*

Tiumen', a town of W. Siberia, at the confluence of the Tjumenka with the Tura, a tributary of the Tobol, 138 miles S.W. of Tobolsk. It is regularly built (chiefly of wood), has 10 stone churches, a mosque, &c. There are manufactures of soap, tallow candles, and textile fabrics, bell and iron foundries, potteries, and shoemaking. T. is also a great centre of transit traffic—boats coming here from the Obi, Irtish, Tobol, and Tura, and unshipping goods for the W. and S. T. is the projected starting-point of the Central-Asian Railway. A great market is held here in January. Pop. (1867) 15,572.

Tiv'erton, a town of N. Devon, 18 miles N. of Exeter by rail, stands on the slope of a hill above the confluence of the Exe and Loman, from whose two fords it derives its Old English name of *Twy-ford-ton.* The chief of its three churches, St. Peter's (136 feet long by 82 feet wide, with a tower 110 feet high), dates from 1073, but was partly rebuilt in the 16th, and has been thoroughly restored in the present century. Other edifices are the town-hall (1864), in late Venetian style, with a tower of 80 feet, a market-house (1830), and the grammar school ('free' in name but not in fact), which, founded by Peter Blundel in 1604, and familiar to every reader of Blackmore's *Lorna Doone*, is now (1879) about to give place to a modern structure. The historic building, however, will remain intact. The cloth trade has declined since the 17th c., and lace-making (employing 358 adults in 1871) is now the leading industry. T. returns two members to Parliament, and publishes two weekly newspapers. Tuesday is the market-day. Pop. (1871) 10,024.

Tiv'oli (anc. *Tibur*), an old Roman town in Italy, province of Rome, beautifully situated on the left bank of the Teverone, 17 miles E.N.E. of Rome. It is interesting from the number of antiquities it contains, the most remarkable of which are the remains of the temples of Vesta and the Sibyl, and the villas of Mæcenas and Hadrian. Near the town is the Villa d'Este, erected in 1549. In 1826 a serious inundation destroyed many houses, and in consequence a new channel was formed for a part of the waters of the river, by the construction of two shafts through the limestone-rock of Monte Catillo, 870 feet and 990 feet long respectively. In 1834 this new channel was opened by Folchi in the presence of Pope Gregory XVI., and a new waterfall was thus formed 330 feet high. Pop. (1874) 8105.

Tlemcen', a town in Algeria, 88 miles S.W. of Oran (q. v.), with which it is connected by railway. It occupies the site of the Roman city of *Pomaria*, and under the Moors, in the 12th and 13th centuries, was a place of great importance, with a pop. of nearly 150,000. It stands on the northern slope of a steep mountain, at a height of 2500 feet, in the midst of a well-irrigated and richly-cultivated country, which especially abounds in fruit-trees. The chief exports are olive-oil, dried fruit, corn, wool, sheep and cattle, dressed alfa cloths, carpets, and leather goods. It has 23 mosques, two of which are fine specimens of Moorish architecture. Pop. 16,722. See Schneider and Hans, *Von Algier nach Oran und T.* (Dresd. 1878).

Toad (*Bufo*), a genus of Amphibian Vertebrata, belonging to the order *Anoura*, in which there is no tail. Strictly speaking, however, the tail, which exists in the tadpole or larva only, disappears on the attainment of adult life. In the T. (which forms a special family, that of the *Bufonidæ*), the tongue, as in the Frog (q. v.), is fixed to the front of the lower jaw, but is free and bifid posteriorly. There are no teeth in either jaw. One foreign genus of toads (*Rhinophrynus*), however, has a tongue which is free in front. The hind limbs are not so disproportionate as in the frog, and the hind toes are only partially webbed. The skin is glandular and warty. Contrary to the general belief, no poison apparatus exists in the T. An acrid secretion is given off from the skin, but it is not poisonous. The habits of the T. resemble those of the frog, but it is by no means so lively as the latter, and appears to prefer dark and shady resorts. The food consists of insects, slugs, and like fare. The common T. (*Bufo vulgaris*) attains a length of 3 or 4 inches. It is of a dark olive-green colour, and deposits its spawn in water in March and April. The Natterjack T. (*B. calamita*) is a second species, found in England and in the S.W. of Ireland. Its colour is a yellowish brown, and a bright yellow line marks the spine. It is said to exude a powerful and disagreeable odour. Among other toads, the Surinam T. (*Pipa Americana*) is a familiar species (see PIPA). The green T. (*B. viridis*) occurs in the S. of France; the *B. tuberosus*, or warty T. of Fernando Po, is a well-known form. The *B. agua* of S. America resides in holes which the creature excavates. The T. is extremely tenacious of life, but experiments by Buckland, Edwards, and others have conclusively shown that there is no truth in the oft-repeated stories of the creature being able to support life when enclosed in solid rock for immense periods of time.

Toad'flax (*Linaria*, the leaves of some species resembling those of the *linum* or flax) is a genus of herbs of the natural order *Scrophulariaceæ*, closely allied to *Antirrhinum* or Snapdragon (q. v.), from which it is distinguished by the corolla being spurred, and the capsule openings being somewhat different. There are about 100 species, natives of Europe, W. Asia, and N. Africa, some of which occur in other countries as introduced weeds. Of the British representatives, *L. vulgare* is the only one generally common. It is easily recognised as a stout, erect, glabrous perennial, with crowded linear-lanceolate leaves and a dense raceme of yellow flowers peering through hedge-bank vegetation on a gravelly soil. It is purgative and diuretic. Three other species are cornfield weeds. *L. Cymbalaria*—the ivy-leaved T.—found on old walls, &c., in many parts of the kingdom, is a native of S. Europe, where it is used as a salad herb. *L. speciosa* is a border annual in gardens.

Toad'stone, a local name applied to the igneous rocks of various descriptions which intersect and are interbedded with the strata of Carboniferous formation in Derbyshire.

Toast. See DRINKING USAGES.

Tobacc'o (according to Humboldt, the native Haytian designation for the pipe used in smoking) is a genus of *Solanaceæ*, natives of America, Eastern Asia, and Australia. Its botanical name is *Nicotiana*, given in commemoration of Nicot, who was the means of introducing the plant into France. The genus consists of sticky-leaved herbaceous plants, with a tubular, bell-shaped, five-cleft calyx; a funnel-shaped five-lobed corolla, having five stamens inserted within the tube; a two-celled ovary surmounted by a simple style; and a two-valved capsule with numerous seeds. The best-known species is *N. tabacum*, a handsome plant of 3-6 feet high, with large oblong lance-shaped leaves and pretty rose or pink flowers. It is extensively cultivated both in the New and the Old World, recent botanical investigation proving that not only is the American and Cuban crop procured from it, but also that it is the source of Latakia T. and of that known as Manilla. Although *N. tabacum* is shown to yield the bulk of the commercial T., other species likewise produce a serviceable article, as *N. Persica*, *N. rustica*, *N. repanda*, *N. multivalvis*, *N. quadrivalvis*, and *N. latissima*. Columbus, when exploring Cuba in 1492, was the first who noted the Indian custom of T.-smoking, and about a century later T. was brought to England by Sir Ralph Lane. Sir Walter Raleigh is credited with introducing T.-smoking into England—a fashion that made rapid progress, there being in 1614 upwards of 7000 T.-shops in and around London. But the smoker was not allowed his enjoyment unmolested either in this country or in other parts of Europe, both Christian and heathen rulers combining to crush the custom. James I. not only tried to suppress it by proclamations, but he raised the duty from 2d. to 6s. 10d. per lb. In defiance of all legislative measures its use increased among all classes, and spread with great rapidity to the various countries of Asia, so that at the present time it is estimated that the annual production of T. throughout the world amounts to more than two millions of tons. Prohibitory laws prevent its cultivation in the United Kingdom.

The cultivation of T. is conducted on a much more extensive scale in the United States than in any other country in the world, the most important centres of the industry being Virginia and Kentucky. Although Kentucky is now by far the largest producer, Virginia was the first state to be specially identified with T.; and the T. trade of that state about the middle of last century laid the foundation of many great fortunes, and gave the first great impetus to the commercial prosperity of the city of Glasgow whose 'Virginia dons' or 'T. lords' were her earliest merchant princes. The following is an outline of T. cultivation and curing as conducted in these states:—The variety of the plant chiefly grown attains a height of from 5 to 6 feet, with large broad leaves which may attain a length of 2 feet. The seeds are first sown in a warm sheltered plant-bed, from which, after the young plants have attained a height of 6 or 8 inches, they are transplanted. In the field the plants are placed in rows 4 feet apart and 3 feet between each, and the earth is heaped up around each plant. After some time they have to undergo the process of 'worming,' a searching for and destroying a T. worm which infests the plantations. Then comes the operation of 'pruning,' or removing such small lower leaves as touch the ground. These leaves are sometimes collected, cured, and sold as 'prunings.' When the plants are at the point of flowering they are subjected to 'topping,' or breaking off of the top of the

stem, whereby the sap which would have gone to flowers and seed is diverted to stem and leaves. 'Sackering' is an analogous operation, consisting in the removal of lateral or axillary buds which readily appear after the removal of the tops. The crop ripens towards the end of September, and the plants are cut down near the ground, the stems split, and by means of the split hung up on sticks in sheds to dry. A fire is lighted in the centre of the shed and kept up for four or five weeks, when it is sufficiently dry. Then ensues the operation of 'stripping,' or removing the leaves from the stem and assorting them into small bundles of different qualities called hands, each containing 5 or 6 ounces. In this state it constitutes dry T., and as such is generally sold by the cultivator; but it does not yet possess the properties or aroma ultimately developed in it. To develop its aroma it is subjected to bulking, which consists in piling up a large circular heap and covering it over with heavy woollen cloths, when it undergoes a sweating or incipient fermentation by which its odour is brought out. T. is a highly exhaustive crop, and various districts with various soils produce very different sorts as far as flavour is concerned. In the trade a great number of varieties are recognised, mostly distinguished by the names of the countries from which they are derived. The principal other manufactured forms known to the public are *bird's-eye*, which is the cut leaf with its stalk (in other kinds the stalk being removed); *shag*, from dark Virginia leaves; *canaster*, coarsely cut Ohio and German leaves; *returns*, a mixture of the cuttings of all kinds. Of roll and cake T. the principal kinds are *pigtail*, *negro-head*, and *cavendish*. The varieties of *cigars* and *cheroots* are innumerable. In *snuffs* the *high-dried* is from the leaf roasted before grinding, the *rappee* from the moist leaf.

According to the agricultural statistics of the United States in 1876, 550,000 acres were devoted to T., the crop from which amounted to 172,000 tons, the yield per acre being thus upwards of 600 lbs. In several states, including New Hampshire and Pennsylvania, the yield is as high as 1600 lbs. to the acre. For the principal European countries the following table exhibits the most recent returns:—

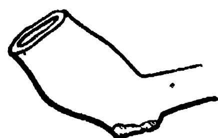
Country.	Acres.	Tons.	Value.
Germany	54,00	31,700	£653,000
Austro-Hungary		62,300	
France	32,000	14,000	480,000
Russia (estimate)	100,000	50,000	
Turkey with Asia Minor and Danubian States (estimate)		31,000	
Holland		6,000	
Belgium		2,000	
Italy		4,500	96,000

T. is also grown to a limited extent in Greece, Sweden, and in Spain. The Spaniards in their colonies have always possessed a monopoly of the finest T. grown in the world. The annual produce of Cuba is stated at 15,000 tons, one-third of which is grown in the celebrated Vuelta Abajo district, from which only real Havana cigars are made. Scarcely less famous is the T. of the Philippine Islands, whence Manilla cheroots are made. Of that T. the Spanish government sells to the value of about £1,600,000 annually. The Dutch also cultivate a very superior class of T. in their East Indian possessions, which is brought to Europe to the extent of 12,000 tons annually; and in Jamaica a variety of T. is now being produced whence cigars in no way inferior to the finest Havanas are made. Throughout S. America, in India, China, and Japan, T. is extensively prepared for local use; but recently Indian T. has been sent to the European market with hopeful prospects.

In Austro-Hungary, France, Italy, Spain, and Portugal, the manufacture of T. is a government monopoly, and in Great Britain, Russia, and Turkey the manufacture is conducted under state surveillance. The following statement shows approximately the consumption per head in several of the principal smoking countries:—

Germany	4·00 lbs.	Hungary	1·91 lbs.
United States	3·52 ,,	Italy	1·55 ,,
Austria	3·25 ,,	United Kingdom	1·45 ,,
France	1·96 ,,	Russia	1·32 ,,

From returns issued by the Board of Inland Revenue, we gather that the quantity of T. cleared from bond for consumption in the United Kingdom has nearly doubled in forty years. Whereas in 1841 the quantity was under 14 oz. per head of population, in 1851 it amounted to 1 lb. ¼ oz.; in 1861, 1 lb. 3¾ oz.; in 1871, 1 lb. 5½ oz., and in 1876, 1 lb. 7½ oz.



T. is used either for smoking, chewing, or as prepared powder for snuffing; but the dirty habit of chewing is not very prevalent, and snuff-taking is now much less common than formerly. Smoking, however, is decidedly on the increase.

Physiological and Medicinal Properties of T.—When T. is taken in a large dose, either in the form of powder or infusion, the following effects are produced, according to Dr. Taylor:—'The symptoms are faintness, nausea, vomiting, giddiness, delirium, loss of power in the limbs, general relaxation of the muscular system, trembling, complete prostration of strength, coldness of the surface with cold clammy perspiration, convulsive movements, paralysis, and death. In some cases there is purging, with violent pain in the abdomen; in others there is rather a sense of sinking or depression in the region of the heart, passing into syncope, or creating a feeling of impending dissolution. With the above-mentioned symptoms there is dilatation of the pupils, dimness of sight, with confusion of ideas; a small, weak, and scarcely perceptible pulse, and difficulty of breathing." These physiological effects may be produced by taking T. internally, by applying it to an open surface, as an ulcer, or by applying the leaves to the skin. There is reason to suppose that T.-juice is frequently used by criminals to drug porter and other liquids, so as to render their victims more helpless. The following analysis of T. *smoke* is given by Dr. Richardson, who has very fully investigated the subject of T.-smoking. Firstly, there is in all T. smoke a certain amount of *watery vapour*, impregnated with various substances from which it may be separated. Secondly, a small quantity of free *carbon* is always present, and it is to the presence of this constituent that the blue colour of the smoke is due. Thirdly, there is a certain quantity of *ammonia* present. Fourthly, *carbonic acid* is always present. Fifthly, T. smoke yields a *product having an oily appearance*, and possessing poisonous properties, which contains three substances, viz., a fluid alkaloid, *nicotine*, a volatile substance having an empyreumatic odour, and an extract of a dark resinous character, having a bitter taste. The carbon, in the case of inveterate smokers, settles on the back part of the throat and on the lining membrane of the bronchial tubes. The ammonia excites the salivary glands, and is supposed to exert a certain influence on the blood; and the carbonic acid may have some influence in producing the languor which accompanies and follows smoking. The empyreumatic substance gives the peculiar smell, and the resinous extract the bitter taste, but the peculiar physiological effects are due to the nicotine. According to Richardson, T.-smoking may produce various functional disturbances: (1) on the *stomach*, causing indigestion. (2) On the *heart*, producing debility and irregular action. (3) On the *organs of the senses*, as dilatation of the pupil, confusion of vision, subjective sounds &c. (4) On the *brain*, suspending the waste of that organ, and oppressing it if it be duly nourished, but soothing it if it be exhausted. (5) On the *nerves*, leading to over-secretion of the glands which they control. (6) On the *mucous membrane of the mouth*, giving rise to smoker's sore-throat. (7) On the bronchial surface of the lungs, sustaining any irritation that may be present, and increasing the cough. (8) T. possesses the power of arresting oxidation of the living tissues, and thus checking their disintegration. 'Before the full maturity of the system is attained, even the smallest amount of smoking is hurtful; subsequently the habit is, in most instances, only prejudicial when carried to excess. It is innocuous as compared with alcohol; it does infinitely less harm than opium; it is in no sense worse than tea; and by the side of high living, altogether, it contrasts most favourably.'

Law of the United Kingdom regarding T.—The culture of T. is prohibited in the United Kingdom, under a penalty of £10, except in a medicinal garden, to the extent of half a pole. Any one having T. so produced is liable to a penalty of £100. Adulteration renders the offender liable to six months' imprisonment, or to a fine of £100. The latter penalty is also attached to cutting leaves in imitation of T. The removal of over 4 lbs. of it, or of snuff above 2 lbs., without a permit, is prohibited under penalty of forfeiture. See Tiedemann, *Geschichte des Tabaks* (Frankf. 1854); *Bibra, Die Narkotischen Genussmittel* (Nürnb. 1855); Fairholt, *T., its History and Associations* (Lond. 1875); and the *Tabakszeitung*, published at Berlin since 1868. Mr.

Arnold is (1879) preparing a catalogue of his unique collection of 500 works on T., its uses, cultivation, manufacture, &c.

Tobacco-Pipe, an implement consisting essentially of a bowl or holder for tobacco, and a stem through which the tobacco smoke is drawn into the mouth. It is in almost universal use, but in form and material it varies much in different countries. Clay, meerschaum, wood, stone, metal, horn, ivory, and amber, are all employed for making pipes in whole or in part. Pipes having long thin stems, straight, bent, or twisted, of white plastic clay, are manufactured in England, Belgium, and Holland; Germany makes them of porcelain; meerschaum and amber pipes come chiefly from Ruhla, Vienna, and Paris, while the 'briar-root' is a specialty of St. Claude in France. (The name 'briar' is a corruption of *bruyère*, a shrub the root of which is gathered extensively in S. France for the pipe manufacture). Turkey and Algeria produce red clay bowls, having flaring mouths, with cherry or jasmine wood for the stems and amber for the mouth-pieces. Pipe-sticks of wild cherry are largely prepared in Germany. The Lapp smokes an iron pipe, and the Ural Cossack a graphite one, while the Samoyede uses a walrus tooth, and the Hottentot a bull's horn for a pipe-bowl. A *chibouk* of Siout clay is smoked in Egypt, and the elegant *hookah* or *narghilhé* in India, Persia, &c. (see NARGHILEH). The primitive form of the hookah—a cocoa-nut containing water and provided with two tubes—is still in use among the Hindus and Tibetans. The calumet, or 'pipe of peace' of the N. American Indians, has a carved bowl of red 'pipe-stone' obtained from a quarry of the Coteau des Prairies, Dakota Territory, while the 'war-pipe of these tribes is the Tomahawk (q. v.). The T.-P. is believed to have been invented in N. America, primitive examples, chiefly in stone, and wrought in fanciful forms, having been excavated from the 'grave-mounds' of Ohio, Mexico, and Central America. Smoking was first practised in England in the 16th c., when, according to Aubrey, the rich used silver pipes, and the poor a walnut-shell and straw. Harrison, in his unpublished *Chronologie*, observes under 1573: 'In these daies the taking in of the smoke of the Indian herb called *Tabaco* by an instrument like a litle ladell . . . is gretly taken up and used in England against Rewmes.' Clay pipes must soon have become common, for their manufacture was an important industry in 1619, from which year dates the incorporation of the craft of T.-P. makers. Early clay pipes had a very small bowl, thick stem, and broad spur, on which the pipe rested unsupported. A specimen of the time of Cromwell, found in Bruntsfield Links, Edinburgh, is shown (half the actual size) in the accompanying figure. Broseley, in Salop, has been a noted seat of the clay T.-P. manufacture since the 17th c. The pipes are made by hand by the following operations:—A piece of moist Pipe-Clay (q. v.) is rolled out into a slender cylinder to form the stem of the pipe, and a lump is left at one end to make the bowl. The stem is bored by driving an oiled iron wire through its axis, after which the clay with the wire still in it is introduced into a folding metal mould, the two sections of which are then brought closely together in a clamp or vice. The pipe-stem being thus formed, a 'stopper' fixed to a lever arm is inserted in the head of the mould, and so squeezes the clay into the form of a bowl. The superfluous clay is next cut away, the wire is withdrawn, and the pipe is taken from the mould, trimmed, and after drying for a day or two is fired in a kiln in which 50 gross of pipes may be fired in eight or nine hours. Lately an ingenious machine for making clay pipes was devised by Mr. Robert Rankin, and made by Messrs. Steven and Struthers, Glasgow, which promises from its productive power to revolutionise the manual industry. Hand-made clay pipes cost 7½d. per gross, or £11 for 480 gross; Rankin's machine turns out the latter quantity at a cost of £2.

Tobacco Pipe—17th c.

Toba'go, a British island in the W. Indies, one of the Windwards, 60 miles S.E. of Granada and 18 N.E. of Trinidad, has an area of 114 sq. miles, and a pop. (1876) of 17,881, an increase since 1861 of 2471. It is 32 miles long by 9 broad, and is traversed by a mountain range which attains a height of 1800 feet. The hills, which are in great part covered with primitive forests, present steep cliffs to the sea, but in other places open upon littoral plains in well-watered valleys. The climate ranges from 75 to 90, and the products comprise pimento, sugar, cocoa-nuts, cotton, coffee, indigo, &c. In 1876 the value of exports (chiefly sugar, rum, and molasses) was £79,670, and of imports £54,582, while the burthen of ships entering and clearing the ports was 26,553 tons. Scarborough, the chief town, lies on Rochley Bay, at the base of a conical hill, 422 feet high, and crowned by Fort King George. Plymouth, on the lee-shore opposite, is the landing-place for the royal mail-steamers. T. was discovered in 1498 by Columbus, who named it Assumption. Its present name is said to have arisen from the fact that early European visitors found the native Caribs addicted to the use of *tobacco*. T. became British in 1764, and is administered by a lieutenant-governor under the governor of Barbadoes.

Tobermo'ry (Gael. 'the well of our Lady St. Mary'), a small town in the island of Mull, Argyllshire, on T. bay in Mull Sound, 30 miles N.W. of Oban. It was founded in 1788 by the British Fishery Company, and has a small but safe harbour with two quays. A new Free Church, in Old English style, was opened January 1879. Pop. (1871) 1344.

To'bit, Book of, is one of the apocryphal books of the Old Testament. There are three theories regarding it:—(1) that it records actual history, which was universally believed up to the time of the Reformation, and is held by some scholars even yet; (2) that it is a moral fiction, an opinion which was first started by Luther; and (3) that it is based upon a real occurrence, preserved by tradition but poetically embellished. The religious character of the book is interesting and important, as showing the phases of faith which prevailed before the time of Christ. Those who believe the book to be genuine history necessarily hold also that Tobit himself was the author of it, since in the first three chapters he speaks in the first person (*cf.* also xii. 20, and xiii. 1). According to this theory it must have been written about 600 B.C. (*cf.* T. i. 15). By modern critics, however, it has been placed as late as 350, 300, or 200 B.C., and even 10, 100, and 130 A.D. There is no dispute as to its having been originally written in Hebrew and Aramaic, from which it was translated into Greek; the LXX. being the oldest extant version of it. See A. Neubauer, *The Book of T.* (Lond. 1878).

Tobolsk', a Russian government of Siberia, bounded W. by European Russia, N. by the Arctic Ocean, E. by the governments of Yeniseisk and Tomsk, and S. by the Kirghiz steppes. Area 531,963 sq. miles; pop. (1873) 1,086,848 (nine-tenths Russians, the rest Tartars, Ostiaks, and Samoyedes). The W. and S. is covered with spurs of the Ural and Altai mountains, from which the land slopes towards the Arctic Ocean in an extensive plain, of which the northern portion, between N. lat. 66° and the ocean, is a frozen swamp for nine months of the year; the middle, between N. lat. 58° and 66°, a forest region with a mild climate, inhabited by hunters and producing fur; and the southern, an agricultural tract with a warm climate, producing the cereals and the fruits of Central Europe. The chief river is the Obi, with its feeders the Tobol and Irtish. Agriculture and cattle-rearing in the S., the collecting of furs in the middle, fishing in the N., besides manufactures in several of the towns, and mining in the district next the Ural Mountains, occupy the people. There is a large transit trade with Russia. Recent exploration voyages by Captain Wiggins of Sunderland have proved the practicability of opening up direct communication by sea with the rivers Obi and Yenesei. The former of these rivers promises to become a permanent channel for the exportation of the corn of T., which can be sold in the English markets cheaper than American corn.—**T.**, capital of the preceding government, at the junction of the Tobol and the Irtish, is 298 miles E. of Ekaterinburg. It was founded in 1590, and is the seat of the general governor and the highest courts of W. Siberia. It has a theological and a normal seminary, a gymnasium, a military school, an arsenal, theatre, and penitentiary. Pop. (1872) 17,427.

Tocantins', a large river of Brazil, rises in the province of Goyaz, and after a northerly course of 1640 miles falls into the river Para (q. v.), the southern arm of the estuary of the Amazon. The chief affluent of the T. is the Araguaya, which joins it in 6° S. lat., and is there as large as the T. itself. Both rivers are navigated by steamers, the T. for 820 and the Araguaya for 943 miles, but the former is much impeded by falls, rapids, and sandbanks. At its mouth the T. is 8 miles wide.

Tocque'ville, Alexis Charles Henri Maurice Clérel de, the eminent French politician and political writer, was born at Verneuil, July 29, 1805. His father was Hervé Louis François Joseph Bonaventure Clerel, Comte de T. (1772–1856), peer of France, politician and historian, and a writer of some merit. T. studied philology at Metz and law at Paris (1823–26). In 1827 he was appointed *juge auditeur* of the tribunal of Versailles. In 1831–32 he was sent by the French government, along with his friend M. de Beaumont, to the United States to inspect and report on the American prison system. They published a joint work on their return, entitled *Du Système Pénitentiaire aux États-Unis et de son Application en France* (Par. 1832; 3d ed. 1845). This treatise, which was crowned by the Academy, recommends the solitary confinement of prisoners. In 1832 T. resigned his office under government, and, after a brief visit to England, gave himself up to the composition of the first of his two great works, *La Democratie en Amérique* (1835–40, 15th ed. 1868; Eng. trans. 4 vols. Lond. 1838). This work is in reality a treatise on the general principles which ought to be taken as the rule of action by all democratic governments. These are, in brief—(1) full extent of individual liberty with all its concomitants (as freedom of the press, &c.); (2) careful avoidance of centralisation. The bearing of this on French politics is obvious. This work was received with the favour it deserved; the Academy awarded to it a special prize of 8000 francs, and a quick succession of honours was bestowed on the author. In 1837 he was appointed chevalier of the Legion of Honour; in 1839 he was chosen by the electors of Valagnes as their representative; and in 1841 he was elected member of the Academy. For some years practical politics occupied all his attention. In 1849 he entered the Odilon Barrot Cabinet as minister of foreign affairs, but the *coup d'état* of 2d December—to which, as may be imagined, he was strongly opposed—drove him from office. He then occupied himself with *L'Ancien Régime et la Révolution* (Par. 1856, 7th ed. 1866; Eng. trans., *France Before the Revolution*, Lond. 1856). This is his greatest work. It was meant to be an exposition of the manner in which the post-revolution France grew out of the pre-revolution France. From a review of the previous state of things it was conclusively proved that the outburst was not, and could not be, caused by any party or sect; on the contrary, it was an absolutely necessary resultant of the pre-existing causes. This work, powerful as it is, was but a fragment of the original design. T. intended to follow it up by others dealing with the great events in the later history of France. He was engaged at these when he died at Cannes, April 16, 1859. Besides the works mentioned above, T. wrote *État Social et Politique de la France* (trans. by J. S. Mill, in *Westminster Review*, 1836), *Le Droit au Travail* (Par. 1848), and a number of reports and papers on prison reform and general, social, and political subjects. All the works of T. are written in a calm, dignified, and powerful style. An ardent lover of liberty, he is yet fair to all sides. His facts are unimpeachable, and the conclusions he draws are invariably logical. No more luminous, severe, dispassionate intellect ever applied itself to politics. It is hardly extravagant to call him the greatest political thinker of his day in France, perhaps even in Europe. His *Œuvres Complètes* (9 vols. Par. 1860–65) were edited by his friend M. de Beaumont, who also edited his *Correspondance* (Par. 1860; Eng. trans. Lond. and New York 1861), to which he prefixed a biographical memoir.

Tod, a now disused weight for measuring wool, which contained 28 lbs. avoirdupois.

To'das or **Torowars'** (a Tamil name for herdsmen), a curious aboriginal tribe confined to the Neilgherry Hills in S. India, where they have attracted much attention. They are a well-built race, and, though only numbering 683 souls (1871), exercise a supremacy over the other hill people. Their sole occupation is the herding of buffaloes, from whose milk they make excellent *ghee*. They wear little else than cotton blankets, and abundant silver ornaments. Their dwelling-places are thatched huts, resembling the tilt of a waggon. Their language is a peculiar branch of the Dravidian Stock (q. v.). See *Primitive Tribes of the Nelagiris*, by J. W. Breeks (Lond., India Museum, 1873).

Todd, Henry John, D.D., an industrious English author, born in 1763, studied at Hertford College, Oxford, where he graduated (1786), took orders, and became successively vicar of Milton, near Canterbury (1792), rector of All Hallows, Lombard Street, London, and keeper of the MSS. at Lambeth Palace, and rector of Settrington, Yorkshire (1820), where he died, 24th December 1845. Among his voluminous works the most valuable are his elaborately annotated editions of Milton and Spenser, his *Illustrations of the Lives and Writings of Gower and Chaucer*, and his expanded edition of Johnson's *Dictionary*.

Todd, James Henthorn, D.D., a distinguished Irish scholar, was born at Dublin, Ireland, April 23, 1805, and graduated at Trinity College, Dublin, of which he became a fellow in 1831. Entering the Church, he was appointed professor of Hebrew (1849), and librarian of Dublin University (1852); was twice chosen Donellan lecturer, became treasurer and precentor of St. Patrick's Cathedral (1864), took a leading part in founding the Irish Archæological Society, and for five years was president of the Royal Irish Academy. He died at Rathfarnham, near Dublin, 28th June 1869. His most important works are *St. Patrick, Apostle of Ireland* (1863), and editions of ancient Irish records, as *The Martyrology of Donegal*, *The Book of Hymns of the Ancient Church of Ireland* (1855), the Irish version of Nennius (1848), and *The Wars of the Gaedhill with the Gaill*.

Todd, John, D.D., an American divine and author, born at Rutland, Vermont, U.S., October 9, 1800, graduated at Yale College in 1822, and at Andover in 1826, and was successively pastor of Congregational churches at Groton (1827–31), Northampton (1833–36), Philadelphia (1836–42), and Pittsfield (1842–72), where he died, August 24, 1873. He wrote a large number of works, some of which attained a wide circulation both at home and in England. The chief are *Lectures to Children* (1834), *Student's Manual* (1835), *Index Rerum* (1835), *Truth made Simple* (1839), *The Young Man* (1843), *The Daughter at School* (1854), *Mountain Gems* (1864), *Woman's Rights* (1867), *Sunset Land, or the Great Pacific Slope* (1869), and *Old-Fashioned Lives* (1870). See *John Todd, the Story of his Life, told mainly by Himself* (New York 1876), edited by the Rev. John E. Todd.

Todd'y is the name given to a saccharine juice drawn from palm-trees in India and Ceylon, and which, when fermented, yields an alcoholic beverage. Whisky T. is a beverage which enjoys undiminished popularity in Scotland. It is made by dissolving a proportion of sugar in a wineglassful of boiling water, adding a glass of malt whisky, and thereafter from one to two glasses more of boiling water. Quantities may be varied according to taste, but T. should contain nothing more than pure sugar, good whisky, and boiling water.

Tod'hunter, Isaac, M.A., F.R.S., son of a dissenting minister, was born at Rye, in 1820, and after studying at University College, London, accepted for a time the post of tutor in a school at Wimbledon, from which he passed to St. John's College, Cambridge, where he graduated Senior Wrangler in 1848. Since then he has resided at Cambridge as fellow, assistant-tutor, and principal mathematical lecturer of his college. He has written numerous text-books on various branches of mathematics, including, besides the usual elementary works on geometry, algebra, trigonometry (plane and spherical), and natural philosophy (2 vols.), standard treatises on more advanced portions, such as the *Theory of Equations* (1861), *Plane Co-ordinate Geometry* (5th ed. 1874), *Analytical Statics* (1866), *Differential Calculus* (7th ed. 1878), *Integral Calculus* (4th ed. 1878), *Mathematical Theory of Probabilities* (1865), and an *Elementary Treatise on Laplace's, Lamé's, and Bessel's Functions* (1875). Perhaps the most valuable of his writings are *Researches in the Calculus of Variations*, which obtained the Adam's Prize in 1871, and *A History of the Mathematical Theories of Attraction and the Figure of the Earth from the Time of Newton to that of Laplace* (2 vols. 1873). He is also author of a volume of essays entitled *The Conflict of Studies* (1873).

Todle'ben, Franz Edward, a distinguished Russian general, a son of one of the Kaufmanns, was born at Mitau, Kurland, May 8, 1818, and educated at Riga, and at the College of Engineers in St. Petersburg. He served in the Caucasus against Schamyl, 1848–51, and under General Schilders in the Danubian campaign of 1853–54, and on the outbreak of the Crimean War was ordered to the defence of Sebastopol against the Allies. By cumulating the fire of the garrison on the works of the Allies, and pushing forward with prodigious energy the construction of the fortifications of defence, T. rapidly turned the tables on his

enemy, and asserted an engineering superiority over the attack. His skill, perseverance, and activity seemed to conjure up, as if by magic, the massive ramparts which prolonged the siege for 349 days (see SEBASTOPOL). T. was raised to the rank of General of Engineers, and received the order of St. George in 1858. The *Journal of the Defence* was subsequently expanded into the *Défense de Sevastopol; Ouvrage rédigé sous la Direction de Lieutenant General E. de T.* (2 vols. 4to, with elaborate maps, 1863-70). In this work, which appeared simultaneously in Russian, French, and German, the technical account of the engineering work is supplemented by a full account of infantry and artillery operations. One of its conclusions is that, in spite of the opinion of many military authorities to the effect that 'it is useless in time of peace to expend immense sums on permanent fortifications: . . . the defence of Sebastopol has proved directly the reverse.' T. was intrusted with the defence of Nicolaiev and Cronstadt, and as 'adjoint' to the inspector-general of engineering (the Grand-Duke Nicholas), he exercised *de facto* the functions of that office from 1860. In September 1877, after the failure of the great attack on Plevna (q. v.), he was summoned to the direction, and completely changing the Russian tactics, completed the investment by the construction of works on the W. side, and so, by intercepting all reinforcements and supplies, ultimately starved Osman Pasha (q. v.) into surrender on December 11, with 20,000 men and 60 guns. On 28th March 1878 T. succeeded the Grand Duke Nicholas as commander-in-chief of the army in Turkey, and in December following was appointed General of the 7th Grenadiers, and by special ukase the regiment received his name.

Todmor'den, a market town on the borders of Lancashire and Yorkshire, 9 miles N.N.E. of Rochdale by rail, is picturesquely situated in a hill-girt valley, watered by the Calder. It contains five Anglican churches and numerous chapels, an Oddfellows' hall, a masonic hall, and a new town-hall (1875) in the Corinthian Order, in front of which stands a bronze statue by Foley of the late John Fielden, M.P. Besides enormous cotton-mills, there are manufactories of calicoes, fustians, dimities, and bobbins, iron foundries, and machine works, &c. T. publishes two weekly newspapers. Pop. (1871) 7836.

Toff'ee is a confection prepared by boiling sugar with a proportion of butter, and casting the boiled compound into cakes on a slab.

To'ga (Lat. 'covering,' from *tego*) was the distinctive dress of a Roman civilian. It consisted of a large piece of white woollen cloth more or less shaped like a segment of a circle, and was thrown loosely round the body in a manner the details of which varied with the fashion of the time and perhaps the taste of the individual. At first the T. was worn alone, but it soon became customary to have a *tunica* under it, and in the latter days of the republic it was superseded even as an upper garment by the more luxurious *pallium* or *lacerna*, still appearing, however, occasionally even under the empire somewhat as our obsolete court-dress does among us. Persons accused of any crime allowed their T. to become soiled (*T. sordidata*) as a sign of dejection; candidates for public offices, on the other hand, whitened it artificially with chalk (*T. candida*); while mourners wore a *T. pulla* of naturally black wool. The *T. picta* or embroidered T. was worn by high officers on special occasions, such as the celebration of a triumph, the ordinary dress of magistrates being the *T. prætexta*, whose only adornment was a deep purple border, and which was worn also along with the *bulla* by children of both sexes.

Toise, an old French unit measure of length, has been superseded since the beginning of this century by the *mètre*. The linear T. contained 6 feet or 72 inches, the square T. 36 sq. feet, and the cubic T. 216 cubic feet. The linear T. was equal to 1·949 mètres, or nearly 6·35 English feet.

Tokat', a town of Asiatic Turkey on the Tosanly-su, a tributary of the Kizil-Irmak, 50 miles N.N.W. of Sivas. It occupies a circular valley and contains a citadel, a splendid but ruinous palace, a bridge, and a mosque. It is the seat of an Armenian archbishop and an important caravan-station. Copper-smelting is actively carried on. Pop. 45,000 (26,000 Turks, 15,000 Armenians). T. is the Byzantine *Eudokia*.

Tokay' is a very celebrated variety of white wine cultivated and produced in Hungary, in the valleys of the Waag and the Gran on the left bank of the Danube. The grape from which T. is made is known locally as *Io Formint*. The berries are medium-sized, of a yellowish-green colour, and grow in large, loose, pendulous branches on a strong vine. Their juice is sweet, and has a very distinct and peculiar flavour. Five different varieties of true T. are commercially distinguished—1st, *Essence*, a sweet light wine containing not more than 7 per cent. of alcohol, and which must be very old (from 40 to 50 years) before it is in perfect condition. 2d, *Ausbruch* T., also a sweet, but more highly alcoholic wine. 3d, *Maszlacs* T. 4th, *Szamoroauy*, or dry T., and 5th, *Ordinari*. The annual produce of the various qualities of T. is estimated to equal 268,000 eimer (upwards of 3,800,000 gallons); but of the very finest quality, which is more a liqueur than a wine in the ordinary sense, very little is produced, and it is strictly preserved for the emperor and a few nobles, in whose hands is the very limited tract of the T. vineyard (Mezes Malé) capable of yielding it. The finest qualities of old T. found in the market sell at prices ranging from £2 to £3 per bottle.

To'kens, a kind of unauthorised coinage, current at certain periods in Britain, first appear in the reign of Henry VIII., and were finally abolished in 1817. James I. and Charles I. endeavoured to restrict the issue of T. to certain privileged parties, but without success. In the end of last century the Bank of England issued *bank T.*, silver pieces of the respective values of 5s., 3s., and 1s. 6d. Ordinary T., which were mostly used by small tradesmen to represent the fractions of a penny, were made of lead, copper, tin, brass, or even leather, and stamped by the issuing shop. The recently-introduced British Workman Public House tallies closely resemble the old T. In the Scotch churches T. are small leaden tallies issued to persons in full communion with the Church previous to the periodic celebration of the Lord's Supper, and handed in by them on their taking their seat at the table. These tallies are now being gradually superseded by cards.

Tokio, the official name of Yeddo (q. v.).

Tök'öly, Emeric, Count, born at the castle of Käsmark, in the Hungarian comitat of Zip, in 1656, on the death of his father, a Protestant noble and insurgent (1671), fled to Transylvania. Here Prince Apafi gave him the command of troops, with which, in 1678, joining the Magyar patriots, he ravaged Moravia, took Kaschau (1682), and marched with the Turks upon Vienna. Treacherously arrested by Kara Mustapha (1685) and sent to the Sultan at Adrianople, T. was released in 1686 and furnished with 9000 Turkish soldiers for further operations against Austria. Created Prince of Transylvania, he defeated Heusler at Yernesi (1689), but was compelled to retreat before the Prince of Baden into Wallachia. He later shared in almost all the Turkish operations against the Austrians, and, excluded from the amnesty that followed the Peace of Karlowitz (1699), lived at Constantinople, dying on his estate of Ismid, 13th September 1705.

To'land, Janus Junius, afterwards **John**, one of the most notable of the 'English Deists,' was born at Redcastle, Ireland, 30th November 1670. He studied at the universities of Glasgow, Edinburgh (where he took the degree of M.A. in 1690), Leyden, and Oxford. In 1696 he published his famous work, *Christianity not Mysterious* (first two editions anonymously, 3d, 1702, with name). The work was to consist of three parts, of which the first done was unpublished. In the first it was affirmed that among the very essentials of true religion were clearness and intelligibility, and that these were contained in Christianity. The second was to be a rational explanation of the reputed mysteries of the Gospels; the third was to show that nothing unreasonable was contained in the Evangelists. The general scope of the book was to limit the sphere of the supernatural, not to reject it altogether; but notwithstanding this it created an immense uproar. The clergy thundered against it from the pulpit, or wrote in refutation of his arguments. In 1697 T. visited Ireland, in the wake of his unpopular work, but found no toleration of its doctrines there. The Irish Parliament, who would have disdained not merely to read but to touch the work, severely condemned at once the book and the author. The former was burnt by the common hang-

man of the city of Dublin, with an imposing display of civic ceremony, and the Lower House of Convocation of the Irish Church, in condemning the book, blamed Parliament for not extending a similar punishment to the latter. T., who was an intensely vain man, was delighted at this uproar, until it became too furious, and he was obliged again to remove from Ireland. The rest of T.'s life was a troubled one. He was in want of money, and had to support himself by doing any stray piece of work that he could procure. His other writings were for the most part fragmentary. The chief were: *Life of Milton* (1698), *Anglia Libra* (1701), *Socinianism Truly Stated* (1705), *Nazarenes* (1718), *Tetrydymus* (1720), *Pantheisticon* (1750). The last of these works 'amounts to a distinct avowal by T. of Pantheism.' He died at Putney, 11th March 1722. A man of inordinate vanity, T. nevertheless possessed considerable powers of mind, and an ardent love of knowledge and speculation. To estimate his full importance he must be known in connection with the religious history of his own day. See Lechler's *Geschichte des Englischen Deismus* (Stuttg. 1841), Hunt's *Religious Thought in England* (vol. ii. Lond. 1871), and Leslie Stephen's *English Thought* (vol. i. Lond. 1876).

Tole'do, a walled town of Spain, capital of the province of the same name, picturesquely situated on a steep hill overlooking the Tagus, 56½ miles S.S.W. of Madrid by rail. Pop. (1877) 17,273. It has twenty-six churches, numerous monasteries, and with its old gates, bridges, and towers, has a very imposing appearance. Its streets are irregular and crooked. The chief buildings are the cathedral, the metropolitan church of Spain, 426 feet long by 216 wide, with five naves supported by 84 columns, 40 side-chapels, in one of which the Mozarabic or Gothic liturgy is still used, many royal sepulchres, rich art treasures, and (in the chapter-house) a library of rare MSS.; the Alcázar, now used as a barrack; the Palace of the Inquisition, now the government buildings; the Vargas Palace, the townhouse, two gates of Arabic workmanship, and two high bridges. Near the Tagus is the great royal manufactory of T. blades, with numerous forges and smithies. T. also manufactures silks, gold and silver stuffs, and exports the famous Marcipan. The University of T. declined in 1498. T. is the *Toletum* of the Romans, a fortified town of Hispania Tarraconensis. It was early famous for its manufacture of steel, and in the time of Julius Cæsar was a great arsenal. From 576 to 711 it was the royal residence of the West Goths.

Tole'do, a city of Ohio, U.S., on the Maumee River, 9 miles from its mouth at Lake Erie, at the terminus of the Wabash, Erie, and Miami canals. It had (1877) 50 churches, 37 schools, a trades' college, a public library of 10,000 vols., and 3 daily and 15 weekly newspapers. T. contains the largest waggon-work in the United States. The other manufactures are bridge and boat building and cabinetmaking, and there is an active trade in general goods. In 1875 T. received 92,946,379 feet of lumber, 15,390,000 laths, and 16,303,000 shingles, and sent by lake and railway to the Eastern states or abroad 740,758 barrels of flour, 6,709,686 bushels of wheat, and 14,928,589 bushels of corn. T. was incorporated in 1836. Pop. (1876) 60,000.

Tolenti'no (anc. *Tolentinum*), a town of Italy, province of Macerata, on the Chienti, 16½ miles S.W. of Macerata by the highroad. It contains the cathedral of *S. Niccolo di T.*, with rich carving and frescoes, also a town-hall, a Gothic gateway, and an art-school. There are manufactures of leather, and of cast-iron and woollen goods. Pop. (1874) 4289. At T. was signed in 1797 a treaty between Bonaparte and Pius VI.; here also the Austrians defeated Murat in 1815.

Tolera'tion is the liberty given to a minority in the state freely and openly to express their opinions on religious and political subjects. Its root idea is the personal liberty of the individual—one man has a right to action unhindered by others unless he injures them. This is a principle which will be admitted by nearly everybody; but the real difficulty is to decide where the exact line of limitation is to be drawn between the general rule and its exceptions.

In the ancient civilised communities of Greece and Rome it may be broadly stated that there was complete religious toleration. The apparent exceptions, of which the most celebrated is the case of Socrates (q. v.), need not detain us. But the reason is plain. Religious ideas had not the force then they have now. Men were for the most part indifferent, and the consequence was that few were inclined to stray from the ordinary paths, and if they did so they were left unpunished. In the modern world all has been changed. A definite system of theological doctrine was evolved from the elements of Christianity. Men were commanded to believe it under the fearful penalty of eternal perdition. Later there were sects, and each believed that its way was the only safe way for man. Then the whole of modern life is richer and more diversified than that of the classic world. Thus the conditions became reversed. There was at once a greater tendency towards diversity, and towards the restraining of that diversity. The argument of the persecutor was briefly this:—Eternal ruin follows the rejection of this doctrine. Those who reject it or who persuade their fellows to do so must for their own sakes and the sake of others be restrained. Although the Reformers were inclined to persecute quite as hotly as the Catholics, this must not blind us to the fact that the principles on which the Reformation was founded finally led to T. The present broke with the past on many important points. A dead level of uniformity became more and more impossible, and men gradually became reconciled to the existence side by side with themselves of men who differed from them. One of the chief causes of religious T. in our own time is the diminished sense of the supernatural. We do not persecute for the same reason that the ancient world did not. Something must also be assigned to higher motives. The true spirit of Christianity has never been better understood than in our own day, and in its essentials the religion of love is pre-eminently the religion of T.

As regards political T., it is evident that it can really exist only in a republic or limited monarchy. No despotic government will admit free opinion if that free opinion be dangerous to it, and where is it not? The ideal of political T. is to be found in a state where the minority have full power to express their opinions. These opinions become (let us suppose) the opinions of a majority. That majority then quietly and constitutionally succeeds to power, and the former majority is now in its turn the minority.

The earliest expression of the principle of T. in English literature occurs in the last chapter of Sir T. More's *Utopia*. Milton's *Areopagitica*, Jeremy Taylor's *Liberty of Prophesying*, Locke's *Letters on T.*, are noble though not quite flawless contributions to the theory of the subject. In our own time the whole matter has been admirably discussed in J. S. Mill's treatise *On Liberty*, perhaps the most valuable of his many contributions to the cause of human advancement.

Tolera'tion Act. See ACT OF TOLERATION.

Toll'ens, Hendrik Van, one of the greatest of modern Dutch poets, was born at Rotterdam, September 24, 1780. He was trained to business by his father, but his bent towards the study of modern languages and poetry could not be resisted. After some translations from French and German, he published the comedies *De Bruilafd* (1799), and *Gierigheid en Baadzucht* (1801), and the tragedy *Konstantijn*, all which he afterwards excluded from the collected edition of his works. He issued three small volumes of *Idyllen en minnezongen* in 1801 and 1805, and gained the second prize for his *Lofdicht op Hugo de Groot* (1803), and the first for *Egmond en Hoorne* (1805). A collection of his *Gedichten* (3 vols. Haag and Rotterd. 1808–15; 5th ed. 1831) was very favourably received; *Vaterlandisch Krijgslied* (1815) and *Wien Nêerlands Bloed* (1816) made him the favourite poet of the people; and the third edition of his *Gedichten* in 1817 found 10,000 subscribers. T.'s longer work, *Tafereel van de overwintering der Nederlanders op Nova Zembla* 1596 *en* 1597 (1816; 9th ed. Leuwarden 1872), is a masterpiece of descriptive poetry. The other chief works of T. are *Romanzen, Balladen, en Legenden* (2 vols. 1818–19), *Nieuwe Gedichten* (1821 and 1829), *Volksliederen* (1833), and *Laatste Gedichten* (1848–1853). During the publication of his *Gezamentlijke Dichtwerken* (8 vols. 1855–57), T. died at Ryswijk, October 21, 1856.

Tolls are placed at turnpikes by road trustees, acting by authority of Parliament. They were formerly used for any kind of custom. See BAR, TOLL; HIGHWAYS, LAW REGARDING.

Tolo'sa, a town in the province of Guipuzcoa, Spain, 16 miles S. of San Sebastian. It has zinc and lead mines, and manufactures of paper and arms. Pop. (1870) 4200.

Tol'tecs, a Mexican race who are supposed to have been supreme in Central America from the 7th to the 11th centuries. They were completely obliterated by the Aztecs (q. v.) and Tezcucans, who held the country when the Spaniards first landed. The latter races were of a martial spirit, but they were indebted for their arts, their civilisation, and their religion to their milder predecessors. The T. present striking analogies to the Etruscans, and in a less degree to the Egyptians and Assyrians. They were great builders, and their religion was a mystic system of great complexity, intimately connected with the study of astronomy, and interpreted by a priesthood, who formed an exclusive caste. See Prescott's *History of the Conquest of Mexico*, book i.

To'lu. See BALSAM.

Tolu'ca, a town of the Mexican confederation, capital of the state of Mexico, 20 miles S.W. of Mexico city by rail. It stands in a fertile district, has manufactures of soap and candles, and exports vast quantities of hams. Many swine are reared in the neighbourhood, and much maize is grown. The district is subject to earthquakes. Pop. 12,000.

Tom'ahawk, a war hatchet used by N. American Indians. It is either wielded or thrown with unerring aim. Sometimes a tobacco pipe is combined with the T., the handle of which is drilled to meet a pipe-bowl fastened to the pole of the axe. The Indians are now supplied with these instruments by traders.

Toma'to (Sp.-American *tamate*), or **Love-Apple** (*Solanum Lycopersicum*), is a trailing annual plant, a native of the warmer parts of America (but not now known in a wild state there), introduced into Europe about the beginning of the 16th c., and since that time cultivated for its fleshy esculent fruit. In S. Europe—particularly Italy—it thrives in perfection, and has become a common article of food. In a green state the fruit is pickled; when ripe it may be eaten raw, or cooked in a variety of ways. An excellent sauce is also prepared from the juice. Several varieties exist differing in shape and colour of the fruit.

Tomb (Gr. *tymbos*), a term applied to a grave as well as to a monument raised over it. In the mounds of earth or stones plentifully found in Europe we see examples of the most primitive burial-places (see BARROW and CAIRN); and the Cromlech (q. v.) and Dolmen (q. v.) of Western Europe are also now recognised as prehistoric tombs. Natural caverns and subterraneous passages and chambers hollowed out by art were likewise early used as places of sepulture in Egypt, Palestine, Asia Minor, Arabia, Greece, and at Rome, Cyrene, and other places. Many ancient rock-cut sepulchral chambers are internally decorated (see CATACOMBS); and others, as those of Phrygia and Lycia, are remarkable for elegant façades worked in the living rock. Of all the tombs of antiquity the pyramids of Egypt (see PYRAMID) are unsurpassed for magnitude and importance. The Greeks had a great variety of tombs—the earth-mound, and buildings constructed of hewn stones developed from it, other detached buildings displaying architectural beauty cut from the rock, and in later times chaste and graceful *steles* or pillars, columns, and small temples, which were chiefly erected in the sepulchres outside the walls of the cities. One of the most splendid sepulchral monuments of all time was the tomb of Mausolus, king of Caria, at Halicarnassus (see MAUSOLEUM). Like those of the Greeks, the grave-monuments of the Romans were of very varied form. The tombs erected by Augustus and Hadrian to commemorate themselves and their successors were remarkable for their size and grandeur. The Via Appia was for several miles adorned with sepulchral monuments; and in 'the street of graves' at Pompeii, specimens of small tombs have been preserved. (See COLUMBARIUM.) During the dark ages mortuary memorials were neglected, but at the *Renaissance* the talents of great artists were again exercised in their construction. Several Indian mausoleums, for instance the Taj Mehal at Agra, are edifices at once elegant and magnificent.

Tom'bac, an alloy of copper and zinc, with a greater proportion of zinc than brass.

Tombig'bee, a river which rises in Mississippi, U.S., and after a S. by E. course of 450 miles through that state and Alabama, joins the Alabama River 45 miles above Mobile, after which the united stream is called Mobile River. The T. is navigable for 410 miles from Mobile Bay.

Tommase'o, Niccolò, a prolific Italian writer, was born at Sebenico in Dalmatia in 1803. After a course of study at Padua, he worked at Florence for the *Antologia di Firenze*, and in 1833 went to France, and after a stay of some years to Corsica. In 1838 he came to Venice, where, in consequence of a petition to the Emperor for a milder exercise of the censorship, he was arrested together with Daniel Manin (January 18, 1848). Liberated by the people on the 17th March, he eagerly entered into the struggle for independence, and was appointed, under the provisional government of Manin, minister of public worship. On the downfall of the Venetian Republic (August 1849) he retired to Corfu, where he prosecuted his arduous studies, though he had become almost blind in consequence of a severe illness. In 1854 he returned to Turin, and in 1859 settled at Florence, where he died May 1, 1874. As a writer T. was distinguished by profound and wide learning, and by the rare union of Catholic feeling with liberalism and patriotism. Of his numerous philosophical and critical works, the principal are *Dell' Educazione* (Lugano 1834; 3d ed. 1836); *Nuovi Scritti* (4 vols. Ven. 1839-40); *Studi Critici* (2 vols. Ven. 1843); and *Della pena di Morte* (Flor. 1865). His political writings he collected and published under the title *Il secondo Esiglio* (Milan, 3 vols. 1862). In philology the chief are his *Dizionario dei Sinonimi della lingua Italiana* (5th ed. 2 vols. Milan 1867), and *Nuovi Studi su Dante* (Tur. 1865). Important for the history of literature are his *Canti popolari Toscani, Corsici, Illirici, Greci* (Ven. 2 vols. 1843); and his *Lettere di Santa-Caterina di Siena* (Flor. 4 vols. 1860). He also edited the *Lettere di Pasquale de' Paoli* (Flor. 1846), and wrote two novels, *Il duca d'Atene* (Par. 1836) and *Fede e Bellezza* (Milan 1852), besides several lyrical poems. See Bernardi, *Vita e Scritti di Niccolo T.* (Tur. 1874).

Tomsk, a government of the Russian Empire, in W. Siberia, between the governments of Tobolsk and Yeniseisk. Area 329,020 sq. miles; pop. (1874) 855,000, chiefly Russians (including, in 1874, 2210 exiles), Tartars, and (about the sources of the Obi) Kalmuks. The S.E. is occupied by the Altai Mountains; the rest consists of great steppes, marshes, and woods. T. forms part of the basin of the Obi (q. v.). In the N.W. are salt lakes, occupying an area of 1930 sq. miles. Cattle-breeding is the main industry, much curbed by cattle plague, which in 1874 destroyed 18,000 sheep. In the same year the Altai mines produced 5405 lbs. of gold, and from the eight imperial smelting furnaces issued 21,912 lbs. of silver, 1,270,645 lbs. of lead, 1,514,856 of copper, 1,100,000 of cast iron. Two great annual fairs are held, Susunkij and Vosnesensk. **T.**, the capital and official centre of W. Siberia, on the Tom, 55 miles from its confluence with the Obi, has several churches and schools, fine private buildings and active trade. A university will be opened here July 1, 1880. Pop. (1870) 25,605.

Ton (Old Eng. *tynan*, 'to hedge,' akin to Goth. *tains*, 'a twig'), a frequent suffix in English local nomenclature (Brixton, Brighton, &c.), rarely met with in Germany (Altona and Osttönne), but frequently in Sweden (Sigtuna, Frotuna, &c.). Its original meaning of 'enclosure' is preserved in its application to the lone Kentish farmsteads of Appleton and Godington; but ordinarily the *ton* became the nucleus of a village, the village of a *town*.

Ton, a denomination of weight used in Britain and America, and equivalent to 20 hundredweights. Hence in Britain it contains 2240 lbs. avoirdupois, and in America 2000 lbs. For the measure of capacity, see TUN.

Tone, Theobald Wolfe, born in Dublin, 20th June 1763, was educated at Trinity College, and coming to London to study law, was called to the bar at the Middle Temple (1789). The outbreak of the French Revolution drew him to politics, and having promoted the fraternisation of Irish Catholics and Dissenters, he founded in 1791 the society of United Irishmen. The discovery of his intrigues with France drove him a fugitive to the United States (1795). Thence crossing to France, he sailed in the squadron, dispatched by the Directory to Bantry Bay (1796); next served a year in the Bavarian army; till, joining once more a French expedition to Ireland, he was taken prisoner, and brought to Dublin, where, sentenced to death by a court-martial, he committed suicide in prison, 19th November 1798. See his *Autobiography* (Wash. 1826), and Madden's *Lives of the United Irishmen* (new ed. Lond. 1858).

Tone, in music, may mean (1) the interval of a second or the distance between two sounds having only one sound between them. In theory some tones are greater than others, but in instruments tuned according to equal temperament (see TEMPERAMENT) tones are all equal intervals, while each T. is of the value of two semitones; (2) tune. The word T. is used in this sense in the term Gregorian T.

Ton'ga Islands. See FRIENDLY ISLANDS.

Tongres (Flem. *Tongren*), an ancient town of Belgium, province of Limburg, on the Jaar, 12 miles N.N.W. of Liège by rail. Its church of Notre Dame (1240) was the first dedicated to the Virgin N. of the Alps, and has a cloister of the 10th c., the oldest in the Netherlands. The hot spring in the vicinity was known to the Romans, and its virtues are described by Pliny. T. has industries in brewing, tanning, and the making of tiles and chicory. Pop. (1873) 7080.

Tongue, the organ of taste, in higher animals is a fleshy muscular body, attached posteriorly to the *hyoid bone*, and occupying the floor of the mouth. It is absent in some Vertebrates, as *Pipæ*, or Surinam toads, and in some fishes (*e.g.* Siluroids). In many fishes it is devoid of muscular tissue. In some birds, also, it is a mere horny investment of the hyoid bone. In the woodpeckers the T. resembles a mobile dart used to impale insects; but in the parrot tribe it is fleshy. In serpents and some lizards the T. is very extensile and bifid at its tip; and in frogs and toads it is immovable in front but free behind. In dolphins the T. forms the floor of the mouth, and is immobile. In Carnivora (*e.g.* Lion) the papillæ are large and horny, and are used in tearing the flesh off the bones of the prey. In the dog, mole, &c., a curious solid body, the *worm* or *lytta* is attached to the under surface of the T. In the Javan porcupine the T. is covered with horny plates. In the elephant it is smooth, and has but little flexibility; but in the Mamidæ or pangolins it is exceedingly long, and provided in the Tamandua ant-eater with recurved spines. In man the T. is bound to the hyoid bone by numerous muscles, and is also attached to the epiglottis by ligamentous folds of mucous membrane. It is connected with the lower jaw by the *genio-hyo-glossi muscles*, and a fold of mucous membrane called the *frænum linguæ*. The *dorsum* or upper surface of the T. in man is convex, and is divided into two halves by a median line or *naphe*. In front the surface is rough owing to the presence of numerous projections or *papillæ*; the posterior part is smooth. The papillæ are the organs of taste. They exhibit three varieties:—(1) the *circumvallate*, numbering from 8 to 10, placed at the back part of the T., and forming a double or V-shaped row behind. Each circumvallate papilla measures from $\frac{1}{16}$th to $\frac{1}{12}$th of an inch in diameter, and consists of a central portion placed inside a cup-shaped depression. (2) The *fungiform* papillæ of the T. are scattered over its dorsal surface, and are of large size and deep-red colour. They are covered each with smaller or secondary papillæ. (3) The *conical* or *filiform* papillæ are situated on the front part of the T. They are of small size and conical form; their colour is whitish, and they also exhibit a division into secondary papillæ. *Simple* papillæ are also found on the T. There are also numerous *mucous follicles* and *glands*. The *substance* of the T. itself is made up of *extrinsic* and *intrinsic muscles*, the latter being arranged to form longitudinal and transverse fibres. The T. derives its nerves from three sources—the *gustatory branch* of the fifth nerve; the *lingual branch* of the *glosso-pharyngeal*; and the *hypoglossal nerve*, the latter supplying the *muscles* of the T., and being therefore *motor* in its nature. The two former nerves are those which supply the T. with *common sensation* and with *Taste* (q. v.). It is a curious but well-ascertained fact that the T. is not essential to *speech*. Many cases are recorded in which little or no difficulty in articulation has followed excision of the T.

Diseases of the T.—T.-tie is a frequent deformity in infancy, which, in certain cases, may prevent the child from sucking, and may, in after life, interfere with articulation. This condition may be very easily and safely relieved by making with the scissors a little nick through the semi-transparent edge of the constricting tissue, all that is necessary being to avoid dividing the ranine artery as it passes along the *frænum linguæ*. *Ulceration* of the T. may occur under the following forms, the irritable, the dyspeptic, the syphilitic, and the cancerous. 1. *Irritable* ulcers of the T. may be excited by the irritation of rough teeth. They are often very painful; are apt to become phagedænic; and are often accompanied by indigestion, owing to the imperfect mastication of food. The treatment consists in extracting or filing down the irritating teeth; correcting the state of the digestive organs, and attending to the local condition of the ulcers. A brisk aperient may be given, and the surface of the ulcers may be touched with nitrate of silver, either solid or in solution. 2. *Dyspeptic ulceration* of the T. may arise without any local irritation. The ulcer, which is usually situated at the middle of the T., is often accompanied by cracks and fissures in other parts of the T., and is frequently the result of psoriasis. The treatment is the same as in cases of dyspepsia; and after the unhealthy state of the mucous membrane has been corrected, the administration of tonics is necessary. 3. *Syphilitic ulceration* of the T. is a very serious disease; and, in its worst form, it appears as a large excavation with foul raised edges, and a sloughy surface on the back or sides of the T., which greatly resembles cancer. Such ulcerations are best treated by the calomel fumigation, which may be effected by adapting a mouthpiece to the vapourising machine, and inhaling the vapour. Five grains of calomel every night is the quantity usually prescribed, or the ulcer may be dusted daily with five grains of grey powder. 4. *Cancerous ulceration* is by far the most serious of the D. of the T. The ulcer generally appears on the side of the T. as a small common ulcer. The appearance of the ulcer is speedily followed by a deposit of hard tissue at its base, which spreads an indefinite distance into the substance of the T., causing pain, difficulty in articulation, loss of appetite, salivation; and the peculiar cancerous cachexia is always present. The disease is apt to spread to the floor of the mouth, or arches of the palate, and the glands below the jaw are generally early affected. If the cancerous nature of the affection is obvious, the only question is whether a surgical operation is to be recommended, and what operation should be performed. If the whole of the diseased tissues can be removed, temporary relief may be obtained; but if the floor of the mouth, or the palate, or the submaxillary glands be implicated, a surgical operation should not be recommended. *Acute inflammatory swelling* of the T., or *glossitis*, is a very uncommon affection; but may be caused by wounds or irritating substances, or by mercurial or iodine poisoning. *Abscess* in the T. appears as a deep-seated, elastic tumour, situated in the body of the T., and in such cases a small incision is all the treatment required.

There are also several congenital malformations of the T., as *macroglossia*, or congenital hypertrophy, the T. being so large that the child cannot close the jaws or speak intelligibly; *congenital fibroid tumour*, which may remain quiescent for a long time; and *fibrous* or other innocent tumours imbedded in the substance of the T. Nævi sometimes, but rarely, occur in the T.

Tongues, Gift of, one of the gifts enumerated in the First Epistle of Paul to the Corinthians (xii., xiv.) as possessed by Christians at that time; and according to the book of Acts (ii.) first bestowed at the Feast of Pentecost immediately after our Saviour's ascension. What ancient interpreters understood by 'speaking with tongues' (Acts ii. 4; 1 Cor. xii. 30) was a miraculous speaking of foreign languages. From the narrative in Acts there can be no reasonable doubt that the writer meant to convey the impression that the disciples were heard to speak in languages which they had not previously understood. The other instances recorded in Acts offer exactly the same phenomena (x. 46, xi. 15, xiv. 15-18, xix. 6). On the other hand, the G. of T. of 1 Cor. was not speaking in foreign languages, but rather in an exalted, ecstatic manner (xiv. 5, 14, 18, 28).

Ton'ic, in music, the first or initial note of any diatonic scale, also called the key-note or final. A composition written in any key closes naturally upon its T.

Ton'ics are medicinal substances which act upon the nutrition of the various tissues so as to restore lost tone by increasing power in the part. T. differ from astringents in that they affect nutrition, and from simple stimulants in that they increase power by increasing nutrition, their influence being permanent and not followed by depression. The administration of T. is indicated in cases of debility depending on actual loss of power, and in convalescence from acute disease; but they are contra-indicated in cases of plethora, and in sthenic inflammatory action. Most T., with the exception perhaps of iron, act primarily through

the nervous system, and produce their effects, secondarily, on the muscular system. The shower-bath, cold sea-bathing, open-air exercise, friction, galvanism, and electricity, may all be classed among tonic remedies; but the chief medicinal T. proper are (1) *simple bitters*, which act upon the stomach so as to invigorate digestion and affect the general nutrition; (2) *bitter* T., as quassia, gentian, calumba, eupatorium, &c.; (3) *peculiar bitters*, such as cinchona and quinia, which possess other properties in addition to those of the simple bitters; (4) *aromatic bitters*, which act upon the alimentary canal, and are dependent for their virtues upon the presence of a volatile oil, *e.g.* chamomile, serpentaria, cascarilla, and angustura; (5) *mineral* T., the various preparations of iron, sulphuric acid, muriatic acid, nitric acid, nitro-muriatic acid, phosphorus, &c.

Ton'ic Solfa' Sys'tem, a system of musical notation denoted by letters. Such a system was advocated by Thomas Salmon so long ago as 1672, in his *Essay to the Advancement of Music*, while a version of a scale invented by Rousseau, in which the notation consists of the numbers 1 to 7, is still used to a considerable extent in France. The originator of the system now in use (called by her tetrachordal) was Miss Glover of Norwich, but it is justly associated with the name of the Rev. John Curwen, who really developed it into an important method of musical instruction. Its main use is in elementary singing-classes, but its disciples are also taught through it the study of composition, harmony, and musical instruments. The key-note of any scale is always called *doh* whatever its pitch may be, the second *ray*, and so on; the notes being indicated by the initial letters **d**, **r**, **m**, **f**, **s**, **l**, and **t**. Higher octaves are shown thus $\mathbf{d}^1$ (doh one octave higher), $\mathbf{d}^2$ (doh two octaves higher), and so on, and lower octaves $\mathbf{d}_1$, $\mathbf{d}_2$, &c. Thus the first lines of the National Anthem appear as follows:—

d d r $\mathbf{t}_1$ d r m m f m r d r d $\mathbf{t}_1$ d.
God save our grac-ious Queen, Long live our no-ble Queen, God save the Queen.

Time and accent marks are represented by dashes and colons; a dash (|) preceding a note representing a strong accent, and a colon (:) a weak one. A dot (.) is half a colon, and a comma (,) half a dot. A stroke under a number of notes signifies that they are to be continued or sung to the same syllable. Thus, in the first line of 'Rule Britannia'—

.$\mathbf{s}_1$ | d : d | $\underline{\mathbf{d,r.m,f : s}}$.d | r : $\underline{\mathbf{r.m,f}}$ | m.
When Bri - tain first at heaven's com - mand.

The addition of *e* to the initial of the note, as *de*, *re*, *me*, &c., denotes a sharp, and of *a*, as *da*, *ra*, *ma*, &c., a flat. In a change of key, the note where the change takes place is printed in a double manner showing its position both in the old and new key. The sign, for example, of a note which was doh in the old and is sol in the new, is $^{\mathbf{d}}\mathbf{s}$. In teaching the system a musical chart of the scale, called the modulator, is used, representing pictorially the relative places of the notes of a scale and its minor modes, chromatics, &c. In the minor mode *lah* is the key-note, the sharp sixth being called *bah* and the sharp seventh *se*. The system has made very rapid progress, and is most extensively used in singing-classes both in this country and in America as well as in the colonies. Whatever may be urged against it as a means of education for trained musicians, who if educated only according to it must submit to absence of acquaintance with the great range of musical literature, it has certainly carried music to a large class of the community which previous movements had failed to reach. A Tonic Solfa Association was established in London in 1853, and the first concert in connection therewith at the Crystal Palace was given by 3000 children in 1857 with great success. Annual conferences of teachers of the system are now held in London and other large towns. The Tonic Solfa College was founded in 1862, and up to 1871 had issued 92,000 certificates of various kinds. A newspaper called the *Tonic Solfa Reporter* is regularly published. For a full account of the system and its history see the numerous works of Mr. J. Curwen, including the *Grammar of Vocal Music* (1848), *An Account of the Tonic Solfa Method* (1854), *The Art of Teaching Music, being the Teacher's Manual of the Tonic Solfa Method* (1876); also the *Story of Tonic Solfa* (1871).

Tonk (*Tank*), the capital of the native state of the same name in Rajputana, India, 218 miles S.W. of Delhi, and 289 N. of Mhow. It is of considerable size, with a wall and mud fort. The *state* of T. comprises six scattered districts. Area, 2730 sq. miles; pop. 320,000; revenue, £110,000. It is the only Mahommedan state in Rajputana, and the chief is styled Nawab.

Tonk'a Bean, or **Ton'ga Bean**, the seed of the *Dipterix odorata*, a large papilionaceous tree of the order *Leguminosæ*, included in the limited group bearing, instead of a pod, a fruit not opening at maturity—a drupe similar to the fruit of the almond. The seed owes its new-mown-hay flavour to coumarin ($C_9H_6O_2$). It is used by perfumers for scenting purposes, and the bean is sometimes carried in snuff-boxes to scent the snuff. The tree is a native of Cayenne. *D. eböensis* of the Mosquito coast has a 'bean' resembling the above, but scentless. There are six other species, all confined to tropical America.

Tonn'age is the registered capacity of a vessel, estimated according to a definite rule. Previous to 1836, the rule for estimating the T. was based upon an erroneous principle, and led to the construction of long narrow vessels. In 1835 a bill was passed to remedy this evil, and a new system of measuring T. was supplemented and improved by the Merchant Shipping Act of 1854. In making the estimate the length of the T. deck (the second deck from below, and therefore the upper deck in vessels with less than three decks) is divided into an even number of equal parts (4, 6, 8, 10, &c.), the number depending upon the length of the ship. At each of these divisions the transverse area is calculated according to a fixed rule; and then beginning with the extreme bow end these areas are numbered 1, 2, 3, &c., to the extreme stern end. To the sum of the first and last (if they yield anything) twice the sum of the remaining odd numbered areas and four times the sum of the even numbered areas are added, and the total sum is then multiplied by one-third the common distance between the areas. This product divided by 100 gives the estimated T. In a steam-ship allowance must be made for the content of the engine-room, which is deducted from the gross T. The estimate cannot be more than approximate, but it affords a sufficiently accurate method for comparing the relative capacities of vessels.

Tonn'age and Pound'age, duties of 3s. on every tun of wine, and 5 per cent. on other imports, were granted Edward III. by Parliament for a limited period, being designed to furnish the Crown with ready money in case of sudden emergencies. They were confirmed to Henry V. for life; but Henry VIII., though levying them from his accession, did not obtain a formal vote till six years later. Regarded gradually as a royal prerogative, they were one of the great points of contention between Parliament and Charles I., who, having endeavoured to exact them by the sole exercise of his authority, had to renounce such claims (1629). Charles II., James II., and William III. received a grant of them for life, but under Anne and George I. they were made perpetual and mortgaged for the public debt, and finally abolished by the Customs Consolidation Act of 1787.

Tönn'ing, or **Tönn'ingen**, a seaport of Prussia, province of Schleswig-Holstein, at the mouth of the Eider, 30 miles S.W. of Schleswig by rail. It has a fine harbour, a beautiful market-place, and an excellent school of navigation. T. carries on a large trade with England in cattle and Danish farm produce. Pop. (1875) 3130.

Ton'quin, the most northerly province of Anam, extends on the W. side of Further India, between lat. 20° and 23° N., along the Gulf of T., and is traversed by the river Song-koi, which enters it from the Chinese province of Yun-nan, and is navigable as far as Hanoi, the capital of T. (pop. 150,000), 40 miles above Hai-Phong, for vessels drawing from 4 to 6 feet. The chief port, the French settlement of Hai-Phong, on the Cua-cam, one of the mouth branches of the Song-koi, can be reached by vessels drawing 14 feet, and a Hong-Kong firm have several small river steamers plying between it and the interior. T. is very fertile, highly cultivated, and full of natural resources. It yields much rice (two crops yearly), cotton, &c.; produces silk, and in 1874 had in operation 14 gold, 7 silver, 3 copper, 1 zinc, 17 iron, and 3 salt mines. The climate is comparatively healthy for Europeans. The inhabitants are poor, and Chinese are indispensable as middlemen for commerce. T. was opened to foreign trade by French treaty of March 15, 1874, but the privilege will be little appreciated till the province becomes the road to Yun-nan, with its vast store of metals. In 1877 the imports

Top'-Shells (*Turbinidæ*), a family of *Gasteropodous* molluscs in which the shell is usually turbinate or top-shaped, but may be pyramidal. It is generally nacreous internally. The *operculum* is horny, and may exhibit a spiral form. In *Turbo* itself the shell is top-shaped with a rounded base. The whorls are convex, and the aperture is large, the operculum being calcareous. The genus *Trochus* also belongs to the T.-S. In the latter genus the shell is pyramidal and the base flattened, the operculum being horny. The common top is the *Trochus zizyphnus*. Others are the *Turbo versicolor*, the *Trochus Imperialis*, and the *Trochus niloticus*.

Tor (Celt. 'projecting rock') is of frequent occurrence in the local nomenclature of Devon and Derbyshire, and possibly may be recognised in the *Tauren* of the Tyrol.

Torbanehill' Min'eral, or **Boghead' Cann'el Coal**, a body very rich in volatile carbon compounds, found near Bathgate in Scotland. The deposit is now nearly exhausted, but at one time it was in great request for enriching gas and for the distillation of paraffin oil. It gave rise to a famous lawsuit, in which the question 'What is Coal?' was keenly discussed from a scientific point of view.

Torfæ'us (Latinised form of **Torfason**), **Thormodr**, a Danish historian, was born at Engö, Iceland, May 27, 1636. In 1662 he was sent by Frederik III. to Iceland to collect MSS. of sagas, and he was afterwards successively appointed royal antiquary (1667), and historiographer-royal (1682). He died at Karmö, near Stavanger, Norway, January 31, 1719. Of his many historical works the chief are *De Rebus Gestis Faröensium* (1695); *Series Dynastarum et Regum Daniæ* (1702); *Historia Vinlandiæ Antiquæ* (1705); *Grœnlandia Antiqua* (1706); and *Historia Rerum Norvegicarum* (4 vols. fol. 1711).

Tor'gau, a town and fortress of the second rank, in the province of Sachsen, Prussia, on the left bank of the Elbe, 47¾ miles E. of Halle by rail. It contains three churches—two Lutheran and one Catholic. The castle of Hartenfels, built in 1481, is now used as barracks. Two good bridges cross the Elbe here. The manufacture of hosiery, weaving, and corn-grinding are the chief industries. Pop. (1875) 10,730. Since the Emperor Heinrich I.'s time T. has been important in German history. It was here in 1530 that the Lutherans drew up the 'T. articles.' The place was fortified by order of Napoleon in 1810. During the War of Liberation it sustained a three months' blockade, and finally capitulated to Tauenzien, 14th January 1814. On this occasion upwards of 28,000 French soldiers (sent hither partly from the Dresden hospital) perished at T. of typhus fever.

Tor'mentil (*Potentilla tormentilla*), a stout-rooted perennial with slender annual stems, which bear sessile ternate leaves and small yellow flowers, with usually four petals and eight sepals. It is common in northern Europe, occurring plentifully in Britain on heaths, moors, &c., up to 3300 feet. The rootstock is sufficiently astringent to be used for tanning. A decoction of it in milk has been given in diarrhœa and dysentery with success, and an extract has been recommended to strengthen the gums and fasten the teeth. Linnæus says the Laplanders colour leather red with the juice.

Torna'do. See WHIRLWIND.

Tor'nea, a small Russian town in N. Finland, in the government of Uleaborg, at the mouth of the river T. It has less commercial importance than the Swedish frontier-town Haparanda, opposite to it. From the summit of the mountain Afvasaxa, 31 miles to the N., the sun is visible during the whole night from the 16th to the 30th June. Pop. (1876) 892.

Tor'nea, a river forming part of the boundary between Sweden and Russia, rises in Lake Tornea-Träsk, and flows S.E. and S., falling into the Gulf of Bothnia after a course of 260 miles.

To'ro, a town of Spain, province of Zamora, on the Duero, 19¾ miles by rail E. of Zamora. It has 21 churches and 14 monasteries. The river is here crossed by five bridges. Once an important city, it has in modern times greatly declined. Pop. 8430.

Toron'to, a city of the Dominion of Canada, capital of the province of Ontario, on the N.W. shore of Lake Ontario, 45 miles N. of the Niagara Falls, 333 W.S.W. of Montreal, 513 S.W. of Quebec, and 500 N.W. of New York. The Bay of T., formed partly by an island, is a sheltered, spacious harbour, capable of admitting the largest vessels that navigate the lake, and defended by a fort which was repaired and remounted in 1864. The city is connected with the principal points of the Dominion and United States by the Grand Trunk, Great Western, Northern, T. Grey and Bruce, and T. and Nipissing railways. It has much the aspect of an English town, and in spite of its low, flat site, and somewhat commonplace vicinity, is a place of striking appearance, being finely laid out, with its streets, laid with tramways, crossing each other at right angles. King Street, the great promenade, runs parallel with the bay, and is intersected by Yonge Street, the second most important thoroughfare. The Esplanade, facing the bay, with its lines of quays and parallel lines of railway, is a great business centre. It is adorned with several good parks, including the Horticultural Gardens and the well-wooded University Park, with its beautiful monument to the volunteers who fell at Ridgeway. Among the principal buildings are the University, completed in 1859; the cathedral of St. James, begun in 1852, with a spire 316 feet high; the cathedral of St. Michael (Roman Catholic); the Osgood Hall, seat of the superior courts; the City Hall, the Opera-house, Post-office, &c. In all, T. has 58 churches, many of which have handsome spires; and as the educational centre of Upper Canada, its teaching institutions comprise, besides the University and University College (separated from the University 1853), a provincial normal school, colleges of physicians and technology, a school of medicine, St. Michael's College, 101 grammar-schools, &c. The University, opened in 1843, has some 250 students. T. has an asylum for the insane, with accommodation for 700, a city hospital, two houses for unprotected children, an orphan asylum (Protestant), a house of providence (Roman Catholic), and various minor charities. It publishes 4 daily and 17 weekly newspapers, besides 1 quarterly, 11 monthly, and 4 bi-monthly periodicals. An extensive manufacturing industry is represented by foundries, flour-mills, tanneries, breweries, boot and shoe stores, car-shops, lumber-yards, furniture-factories, &c. Within a short distance of T. are some of the most valuable and easily-wrought iron ores in the country, and mineral coal from the mines of Pennsylvania and Ohio can be offered in T. at a moderate price. The advantages thus afforded for smelting, and the proximity of and easy access to the United States market, were sufficient to induce a large English company to transfer its business-plant thither in January 1879. In 1871 the value of manufactures in T. was estimated at $13,686,093. During the open season the harbour is visited daily by the magnificent lake steamers from Montreal and other ports. For the year ending 30th June 1875 the exports (lumber, flour, wheat, cattle, prepared meats, &c.) amounted in value to $14,716,824, and an imperfect return of imports to $2,000,000. A firm of T. is negotiating (February 1879) with the British Government for the supply of the troops in Cyprus and Gibraltar with beef and mutton. In 1875 the temperature in the shade ranged from 10·2 F. in February to 66·6 in July, and the rainfall for the year amounted to 18·98 inches. Pop. (1861) 44,821, (1871) 56,092. T. returns two members to the provincial parliament, and two to the Dominion House of Commons. The name T. is supposed to be of Indian origin, but is of unknown meaning. The town, founded by General Simcoe in 1794, bore the name of York till 1834, when it was incorporated as a city. The capital of Upper Canada till 1841, and the seat of the united government alternately with Quebec from 1849 till 1858, it has been the capital of Ontario since 1867.

Torpe'do (*Torpedo*), the name given to species of *Elasmobranchiate* fishes belonging to the family *Torpedinidæ*. In this group the body is rounded and blunt-shaped in front, the back convex and unarmed, and the tail-fin triangular. The teeth are pointed, and the breathing apertures are serrated. The *T. vulgaris* is known as the Electric Ray and Cramp-fish. It is one of the electrical fishes, and can give very powerful shocks. The *electrical organs* consist of two honeycomb-like masses placed in the sides of the head. Each organ is made up of vertical gelatinous plates, separated by membranous partitions, and richly supplied with nervous filaments from the eighth pair of nerves. This arrangement of parts presents a close resemblance to a voltaic battery. The production of electricity is effected by the conversion of nervous energy into electricity by these specialised organs,

very much as nerve-force is converted into motion by muscular tissue. The electrical shocks decrease in violence after each emission of electricity, thus showing that the expenditure of nervous power diminishes the electrical force.

Torpe'do, a submerged military mine used in war for the purpose of destroying vessels belonging to an enemy. The name was first given by Robert Fulton, the American, to maritime defences invented by him, and which he successively offered to the French, British, and American Governments without success, their use being thought by the public of his time little short of diabolical. His system included four classes of torpedoes, viz.: (1) Buoyant mines, anchored and exploded by contact with the enemy's hull; (2) Line torpedoes, destined to be set adrift and fouled by the cables of the hostile fleet at anchor; (3) Harpoon torpedoes, to be discharged from guns by clockwork; (4) Block-ship torpedoes, to be carried on projecting booms and exploded by contact with the enemy. All those devices, except the third, are included in an improved form in the modern system. To another American, Samuel Colt (the inventor of Colt's revolvers), we are indebted for the introduction of electricity as an igniting agent. During the war between the allied Powers and Russia in 1855, Sebastopol, Cronstadt, and other Russian ports were protected by torpedoes or submarine mines designed by Professor Jacobi, but no serious damage was done by them, the charge of powder (about 9 lbs.) being too small. The fuse consisted of a small bottle of sulphuric acid embedded in a mixture of potassium, chlorate, and sugar, the breaking of the bottle by contact with the vessel effecting ignition. In the Franco-Austrian war of 1859, Colonel von Ebner designed an elaborate system of electrical mines for the defence of Venice, but no opportunity occurred of putting it to the test. The first occasion on which torpedoes were used on a grand scale was the Civil War in America. The Confederates had a large seaboard and many positions assailable by rivers to defend, and were altogether destitute of a fleet. They therefore established a torpedo factory at Richmond, from which hundreds of these deadly engines issued forth to commit terrible havoc upon the enemy. The Federals thereupon took retaliatory measures of the same kind. During the war seven ironclads, eleven wooden men-of-war, six army transports, and many smaller vessels belonging to the United States, were destroyed by torpedoes, while the Confederates lost three ironclads from their own mines, and one from the operations of the enemy. The Confederate system embraced—(1) Stationary torpedoes or sea-mines; (2) Automatic drifting torpedoes; (3) Infernal machines; (4) Offensive spar torpedoes; and (5) Submarine boats. The *stationary torpedoes* included simple frame torpedoes. Each shell of these contained 25 lbs. of gunpowder to which a fuze similar to that used by Professor Jacobi was attached, protected by a thin lead cap to be crushed by the hostile vessel. The swaying boom and turtle torpedoes were improvements, having a larger charge and being free to move in the water. General Rains devised an exceedingly sensitive fuze of fulminating mercury and fulminating silver which he used in his barrel or conical-shaped torpedoes. Electrical mines with enormous charges of powder worked by an operator on shore were also used by the Confederates. The *Commodore Jones* was destroyed on the James River, May 6, 1864, by a T. of this type. *Automatic drifting torpedoes* were used for rivers where the current could be depended on to carry them down to the hostile fleet, and as a protection against them, nettings were placed round ships at anchor. *Infernal machines* were explosives intended to be smuggled on board the enemy's vessels, and there to effect destruction. Their use was not legitimate in war. Such was the 'coal T.,' a metal case containing several pounds of gunpowder cast and coloured like a piece of coal—when thrown into a furnace the explosion of the boiler followed. The 'horological T.' contained a charge of powder to be fired after a fixed time by a clockwork arrangement. *Offensive Spar Torpedoes:* Outrigged spars from 20 to 30 feet in length were used for these. The Confederates used copper cigar-shaped torpedoes about 35 feet long charged with 50 lbs. of gunpowder, and driven by engines at a speed of about seven knots per hour. Under cover of night these boats approached the hostile fleet. Others were carried in ordinary steam launches. Thus Lieutenant Cushing blew up the *Albemarle*. The *Submarine boats* used by the Confederates were not found to work well. They were designed to pass under the enemy, dragging a floating T. to explode on contact with the enemy's hull. One boat of this kind was constructed of boiler iron, 35 feet long, propelled by hand at four knots an hour, and could remain submerged at any depth for half an hour. She had a crew of nine men. In her preliminary trials she sank three times and drowned twenty-three men. Eventually she sank a United States sloop and herself at the same time. Since the American war, although wonderful improvements have been made in torpedoes, they have not been tried on a very extended scale. During the Paraguayan war a fine Brazilian ironclad was sunk by two anchored torpedoes with sulphuric-acid fuzes. Torpedoes guarded the German ports during the war of 1870-71, and effectually scared the French navy. The *Ball of Verdun* was invented during this struggle; viz., a large iron ball, 3 feet in diameter, charged with gunpowder and provided with a clock-work train arranged to ignite the ball by the firing of a pistol after a certain time. The centre of figure and the centre of gravity being coincident, and the ball being little heavier than water, it was able to roll along the deepest part of the current of a river, thus eluding detection. Similar balls were used during the siege of Paris to convey letters into the capital. In the first stages of the Russo-Turkish wars there were several encounters between ships of war and T. vessels. On the night of May 25, 1877, Lieutenants Dubasoff and Shestakoff in the most daring manner steered a couple of steam launches into the centre of the Turkish flotilla on the Danube, and succeeded in blowing up a monitor. These vessels were painted black and screened with iron, having each two torpedoes attached to the end of a long spar projected from the bow. A long light chain was attached to the torpedoes, and they were connected with the boat by electric wire. On coming to the bow of the monitor, the T. was dropped from the spar and attached by the chain to a rope suspended from the bow. The steam launches shot away to the full length of the electric wire, and on the current carrying the torpedoes against the bottom of the ship, the officers in command of the launches effected the explosion by firing an electric battery. Notwithstanding that the machinery of the T. launches was almost noiseless, the attack could scarcely have succeeded had the Turks had efficient lighting and watching. On 1st July 1877 a Turkish monitor successfully fought four T. boats, the boats failing to strike her with their torpedoes.

The torpedoes in use at the present day may be broadly divided into defensive and offensive torpedoes. The former, which are simply submarine mines, are essential for harbour defence. They differ but little from mines used in land fortifications, and being worked from shore are usually managed by military engineers. For the charge gun-cotton is now more common than gunpowder, as it occupies less space and is impervious to wet, while electricity is the usual igniting agent. The mines are usually arranged to be fired at will or automatically by the touch of the vessel. In the latter case a circuit-closer or circuit-breaker is employed. The mines are retained in their positions by sinkers, of which there are two patterns, the *saddle* and the *mushroom*. The core of the connecting cable consists of a strand conductor of four copper wires, tinned, with a case of vulcanised indiarubber. As regards offensive torpedoes much has been done of late years, but the utmost secrecy is observed among different nations as to discoveries in this important branch of warfare, particularly in the mechanical details and the manner of adjusting and fitting the several manufactured parts. Some offensive torpedoes require the skill and daring of a sailor to move them into a position and explode them at a destructive range; others, such as fish torpedoes, may be operated either from land or shipboard. Among the principal known forms of offensive T. are the offensive spar T., as previously described, the Harvey T., and the Whitehead T. Many spar torpedoes have been constructed for the English navy, and they will always be popular among sailors on account of the dashing courage and adventurous daring which they require. Some have considerable armaments, and are capable of developing a speed of 18 miles, being propelled by noiseless machinery. The *Harvey T.* was invented by Captain Harvey of the Royal Navy. It was successfully tested at official experiments at Portsmouth in 1870. The largest patterns contain a charge of about 100 lbs. of gun-cotton or dynamite in a copper vessel encased in wood, about 4 or 5 feet long, 2 feet deep, and 6 inches wide, ballasted so as to ride vertically in the water. The vessel is attached to a fast steamer by wire-rope, and the T. is designed

to strike the hull of the enemy by means of breaks and levers. The first experiments with the *Whitehead T.* were made by Robert Whitehead at his celebrated factory at Fiume, Austria, upon the suggestions of Captain Luppis of the Austrian navy. The torpedoes of this kind recently on view at Woolwich Arsenal were in long cigar-shaped cases of thin steel, built in sections well screwed together, about 17 feet long and 15 inches wide in the widest part. The first compartment contains a charge of gun-cotton (in some 360 lbs.), to be fired by the forcing of a roughened pin into a cap of fulminate on contact with any object. The second compartment contains Mr. Whitehead's secret contrivance, giving the operator control over the machine, so that he can make it run at any regulated depth. The next section is a reservoir for compressed air, then comes the machinery, and last of all the screw and rudders. A full description of this T. will be found in the *Illustrated London News* of May 18, 1878. It is fired from a ship through an impulse tube, and when it finishes its run it rises to the surface of the water, being towed back by a boat. Experiments on a large scale with the Whitehead took place at Portsmouth on March 2, 1878, in presence of eighty members of Parliament. The torpedoes sped straight as an arrow, with great nicety as to the required depth, at a speed of from 12 to 14 knots. Several Whiteheads captured from the Russians recently lay at Constantinople. Their speed was estimated at 27 knots an hour for 200 yards, and the full distance of their run was 1800 yards. In the words of Lord Charles Beresford (speech in House of Commons, March 19, 1877), the Whitehead T. can do anything but speak. It can be set to explode on contact, or after a definite time, or within 1000 yards of the hostile object. It could make a hole in any vessel of 75 feet area, and sink any ship afloat. The invention of the *Fish T.*, steered by electricity, has superseded the use of submarine boats. It was patented by Colonel Ballard, R.E., in August 1870, and has been elaborated by inventors of various nationalities. In consists of a boat of the Whitehead class, which unwinds a coil of insulated wire, through which an electric current can be passed from a battery on shore or shipboard at will to certain electro-magnets. The motion of the fish is under the perfect control of the manipulators, and it may be propelled by compressed air, steam, or liquefied carbonic acid. The manufacture of torpedoes for the British Government is carried on at the Royal Laboratory, Woolwich, and qualified instructors are attached to the navy to teach their manipulation to the sailors.

Modern ironclads are such enormously costly structures, that naturally the utmost ingenuity has been exerted to discover some means of defence which could make them safe from these insidious and deadly attacks. Wire nettings are somewhat cumbersome, as they hinder the vessel's speed, while a Whitehead T. will go through half an inch of netting. It has been found that the explosion of a mine will burst or destroy all fixed submarine torpedoes within a radius of 100 feet. In the experiments at Portsmouth on March 2, 1878, it was shown how such mines could be fired by electricity from steam launches, without a soul on board, acted on by an operator in another vessel. During the critical months of 1878, while the British fleet lay in the Sea of Marmora, and when war might any day have broken out between Great Britain and Russia, extraordinary vigilance was shown by Admiral Hornby to guard his ships against night attacks. Electric lights from the tops turned the immediate surroundings of the ships from night into day, while steam launches, with 9-pounders, and with armed crews, prowled round them all night. Outposts were established at the outlets on the entrance to the bay, and the Gatling guns were kept constantly loaded. Outrigged spars and wire nettings also formed part of the defence. In February 1879 the Admiralty despatched men to various ports in the kingdom and in India to give instruction in T. practice. See *Submarine Warfare, Offensive and Defensive* (New York 1869), *Des Explosions au sein de l'eau* and *Études sur les Effets des Explosions sous-marines* in *Revue Maritimes* (Par. 1877), Ehrenkrook's *Fischtorpedos* (Berl. 1878), and *Geschichte der Seeminen und T.* (Berl. 1878).

Tor'quay, a celebrated English watering-place in Devonshire, beautifully situated on the N. side of spacious Tor Bay, 23 miles S. of Exeter, and 210 from London by rail. It is partly built in the coves and the narrow valleys that run inland to the coombes and plateaux of Dartmoor, partly on the terraces that line the great limestone cliffs, and from the sea it presents a singularly picturesque appearance, its white houses gleaming from out luxuriant foliage, with the dark background of the upland Tors. As a watering-place it became known only about the beginning of the century, but it soon acquired a European celebrity, and has increased with unusual rapidity. Tormohun is the mother parish, and Torre Church is the only church not of modern date. Of the great Premonstratension house of Tor Abbey, founded in 1196 by William Lord Brewer, there are some interesting remains connected with the Tor Abbey of modern times. Under the modern house are some crypts, the character of which was first ascertained during some restoration works in 1874. A museum, in Venetian-Gothic style, was erected 1874–75, at a cost of £2300, and an aquarium and winter-garden was projected in 1876, at a cost of £30,000. A new pier, built by Sir Lawrence Palk, is causing T. rapidly to rise into importance as a yachting station. The great attraction of T. is, however, its fine climate. With a mean winter temperature of 44°, or 3° above that of Greenwich, it has a summer average of 1° below Greenwich, or 55°. Many of the inhabitants are employed at Blacklee's Royal Marble Works, St. Mary Church, in preparing the famous Devonshire marbles, of which Petitor furnishes a richly-varied supply; the fossil varieties of these marbles are known commonly as madrepore. At T. is made the finest terra-cotta ware now produced, and the works of the Watcombe and T. companies are open to visitors. Pop. (1801) 1000, (1871) 21,657; (1879) estimated at 26,000. Torbay was the landing-place of William of Orange in 1688. In the vicinity are Kent's Cavern (q. v.), and Brixham Cave, discovered in 1851, both of which are rich in prehistoric remains. Kent's Cavern has been undergoing systematic exploration for several years on behalf of the British Association by Messrs. Vivian and Pengelly. See Thomson's *T. Past and Present* (Lond. 1877). The latest and most complete account of the town is given in J. T. White's *History of T.* (1878).

Torque (Lat. *torquere*, 'to twist'), an ornament for the neck worn by the barbaric nations of antiquity, and formed of wires of gold or other metal twisted into a rope-like shape usually terminated by clasps, or of small rings linked together like a chain. Among certain Asiatic nations it served as a sign of distinction, while Celtic peoples regarded it as a national ornament. The Romans, who adopted it from the Gauls, used it as a reward for valour. The accompanying figure represents a bronze T. found on the Quantock Hills in Somersetshire. A neck ornament, in which the primitive form of the T. is retained, is still worn in some parts of India.

Torque.

Torr'e del Gre'co, a town in the province of Naples, Italy, on the Gulf of Naples, 7½ miles S.E. of Naples by rail. It lies at the foot of Mount Vesuvius, on the lava stream of 1631. There are fisheries, and manufactures of coral articles and of wine. In 1875, 234 vessels of 14,717 tons entered and cleared. Pop. (1874) 18,950. Founded by the Emperor Friedrich II., T. suffered severely from earthquakes and eruptions in 1737, 1794, 1856, and 1861, yet the inhabitants have always rebuilt their homes on the same spot.

Torr'e dell' Annunzia'ta, a town of the province of Naples, Italy, on the Bay of Naples, 12½ miles S.E. of Naples by rail. It has manufactures of macaroni, paper, and weapons; also fisheries. In 1875, 571 ships of 66,238 tons burden entered and cleared this port. Pop. (1874) 15,321.

Torr'es-Strait, discovered by Torres in 1606, separates Australia from New Guinea, and is 200 miles long, with a minimum breadth of 80 miles, and a depth varying from 48 to 120 feet. Numberless sandbanks, coral reefs, and islands, together with swift tides and fierce squalls, make its navigation dangerous, especially to sailing-vessels. The largest islands measure from 4 to 35 miles in circumference, and are of volcanic formation, lofty and wooded.

Torres-Ve dras, a small town of Portugal, Estremadura, on the Sizandro, 30 miles N. of Lisbon, celebrated in connection with the famous lines of defence behind which Wellington retired after the vain effort to hold the Portuguese frontier against the

French. The outermost of the lines stretched 29 miles from Alhambra on the Tagus to the sea at the mouth of the Sizandro; the second, from 6 to 10 miles behind, from Quintella on the Tagus to the mouth of the St. Lorenza, a distance of 24 miles. The third line, much shorter, lay S.W. of Lisbon, at the very mouth of the Tagus, and was meant as a cover if embarkation were necessary. The whole lines consisted of 152 redoubts, with 534 pieces of ordnance and 34,125 men. The 'great work at Monte Agraça' had a perimeter of 2435 feet, an armament of 25 guns, and a garrison of 1590 infantry. The Allies entered the retreat which the foresight of Wellington had provided in October 1810, and held the French at bay till March 1811. The enemy then retired, and Wellington issued on his career as the liberator of the Peninsula.

Torricell'i, Evangelis'ta, an Italian mathematician and physicist, was born at Piancaldoli, in the Romagna, October 15, 1608, and came in 1625 to Rome, where he studied geometry under Castelli, and subsequently acted as amanuensis to Galileo, after whose death he was appointed by the Archduke Ferdinand II. professor of mathematics and philosophy at Florence, where he died October 25, 1647. T. published *Opera Geometrica* (Flor. 1644), but is chiefly known for the invention of the mercurial barometer (1643). The space above the mercury, which is filled with mercury vapour, is frequently called the *Torricellian vacuum*. See BAROMETER.

Torr'ington, a market-town of N. Devon, 6 miles S.S.E. of Bideford, crowns a hill-top on the right bank of the Torridge, and has a church which, blown up during Fairfax's attack in 1645, was thoroughly restored (1863). T. also contains a townhall, market-house (1842), literary institute, &c.; and besides brewing and tanning, manufactures gloves and fancy boxes. Pop. (1871) 3529. T. played an important part in the Great Rebellion, and gave the title of Earl to General Monk, who was born in the neighbourhood.

Torshok', a town of Russia, government of Tver, on the Twerza, 20½ miles E.S.E. of Oshtashkov by rail. It is one of the oldest towns in Russia, and was formerly fortified. It has a fine cathedral and twenty-two other churches, and carries on manufactures of wax, leather, gold and silver embroideries, besides a trade in corn. Pop. (1871, *St. Petersb. Cal.* 1878) 12,910.

Tor'sion, in mathematics, is the rate at which the osculating plane rotates per unit of length of the curve, where by *osculating plane* is meant the plane containing the tangent and the radius of curvature. A plane curve has no tortuosity; hence a *tortuous* curve, called by some a curve of double curvature, cannot lie in a plane. In mechanics the term is applied to the force with which a body, such as a thread, wire, or slender rod of metal, resists a twist. Experiment shows that within certain limits the T. is proportional to the angle through which the body is twisted, and that these limits depend upon the elasticity of the material. If a metallic wire stretched by a weight is twisted through a moderate angle, and then left to itself, it will begin to untwist and then to retwist, and so on in a series of perfectly isochronous and regular oscillations. The measure of the T. depends on the time of oscillation.

The *T. balance* takes advantage of these properties to measure small forces; and for this purpose was used by its inventor, Coulomb, who not only investigated the laws of T., but established by its means the fundamental laws of electric and magnetic attractions and repulsions. A similar apparatus has been used by Cavendish, Baily, and others in estimating the density of the earth.

Tor'sion is a method employed in surgery for arresting hæmorrhage from small arteries. The bleeding vessel is seized by a pair of forceps, drawn out for about a quarter of an inch, and then twisted round several times till it cannot untwist itself. T. is much preferable to ligature when small arteries are opened during an operation, as in the removal of a large tumour.

Torsk (*Brosmius vulgaris*), a Teleostean fish also known as the 'Tusk,' allied to the *Gadidæ* or cod, and found in the N. Atlantic. It has a small head, a long body, with a long and unbroken dorsal fin, an undivided tail, and a long anal fin. There is one *barbule* or tentacle under the chin. The colour is a dingy yellow above and white below. The T. lives in deep water. It is caught in large quantities, and when salted and dried is one of the most savoury of stockfish. The chief T. fisheries are off the Faroe and Shetland Islands, off the Norwegian coasts, and on the shores of Iceland.

Tor'so (Ital. 'a trunk'), a name in art applied to a statue of which only the trunk remains, as the famous 'T. of Hercules.'

Tor'stensohn, Lennart, a celebrated Swedish general in the Thirty Years' War, born at Torstena, August 17, 1603, became in his fifteenth year page to Gustaf Adolf, and in 1630, as captain of the bodyguard, accompanied the king to Germany, where he highly distinguished himself in the battle on the Lech, April 5, 1632. He was taken prisoner before Nürnberg, August 24, 1632, and subjected to rigorous confinement for six months in a subterranean dungeon at Ingolstadt by Maximilian of Bavaria, which shattered his health and obliged him to return to Sweden. In 1635 he returned to Germany, and took part in most of the battles under Bernhard of Weimar and Baner, the successors of Gustaf. In 1639 he returned to Sweden, but on the death of Baner in 1641 he became commander-in-chief of the Swedish army. After recruiting his army, he entered Schlesien through Sachsen, took Glogau and Schweidnitz, turned into Moravia and captured Olmütz. Obliged to retreat into Sachsen before the Archduke Leopold and Piccolomini, he turned upon his pursuers and inflicted a severe defeat at Breitenfeld, November 2, 1642. In the spring of 1643 he threatened Prague, and relieved the beleaguered Olmütz. In consequence of Denmark's declaration of war against Sweden, in December he burst into Denmark, and in six weeks subjugated the whole peninsula, with the exception of the fortresses Rendsburg and Glückstadt. After defeating the Austrian general Gallas at Jüterbok, November 23, 1644, he returned into Bohemia, defeated Katzfeld at Jankau, March 6, 1645, overran Moravia, pressed forward to the Danube, and demolished the fortifications on the Wolfsbrücke before Vienna. He now laid siege to Brünn, but its obstinate defence, and a pestilence among his troops, obliged him to retreat into Bohemia. Exhausted by sickness, he was obliged to leave the command to General Wrangel, and return to Sweden. He was made Count of Ortala by Christina in 1647, and died at Stockholm, April 7, 1651.

Tor'toise, the name given to various genera of *Chelonian Reptilia* belonging to the families *Testudinidæ* and *Emydidæ*. In the T. the limbs, unlike those of the Turtle (q. v.), are adapted for walking. The toes are distinct and provided with nails. The *shell* or *carapace* is strongly convex and of square shape; and the head, limbs, and tail can be withdrawn into the shell. The food consists chiefly of vegetable matters. Of the T. the most familiar species is the *Testudo Græca* or European T., found in S. Europe. It attains a length of from 6 to 8 or 12 inches, hybernates during winter, and lives to a great age—sometimes as much as 100 years. This is the kind hawked in the streets. The *Testudo Indica* or Indian T. is over 3 feet in length. It inhabits the Seychelles and Galapagos Islands; both its flesh and eggs are esteemed delicacies. The Sopher (*T. Sopher*) or Pllungofa T. is a native of America, attains a length of 13 inches, and is of a brownish-yellow colour marked with dark brown. The genus *Pyxis* includes the *P. arachnoides* of India and Madagascar, notable for its ability to close its shell by a kind of movable lid. The Terrapin includes the chicken T. (*Emys reticularia*) and the lettered T. (*E. scripta*). The wood T. belongs to the genus *Kinosternon*, and is common in N. America; the box T. (*Cistudo Carolina*) is another American species which has the power of closing its shell at will. In the Sewalik hills of India and in Tertiary deposits the fossil remains of a giant T. (*Colossochelys Atlas*) have been found. This animal attained a length of 18 or 20 feet, and may possibly have survived the human period.

Tor'toise-shell, the name given to the epidermal and horny plates (representing skin-structures) which cover the back of the *Chelonia imbricata*—the Hawksbill Turtle. T. should thus more properly be called 'turtle-shell.' These plates are overlapping scales, and may attain a length of over 12 inches. They are susceptible of a high polish, and in this state, and when thinned, exhibit the variations of colour familiarly seen in T. This substance is remarkably ductile under heat. It is used for making combs and like articles. The plates are taken off the back of the animal, which is then allowed to escape, the subsequent growth of the plates, however, being imperfect.

Torto'la. See VIRGIN ISLANDS.

Torto'na (anc. *Dertona*), a town in N. Italy, province of Alessandria, on the Scrivia, a feeder of the Po, 13 miles E. of Alessandria by rail. Its old *duomo* (a Jewish synagogue till the time of Constantine) was destroyed accidentally by gunpowder in 1609; that erected in 1575 contains several fine pictures, and a grand sarcophagus with Greek and Latin inscriptions. T. has a rich library (chiefly ecclesiastical), a large theatre, and industries in silk-reeling and the making of coarse cottons. Pop. (1874) 13.504. T. was a free republic in the Middle Ages.

Torto'sa (anc. *Orthosia*), a town of Spain, province of Tarragona, on the left bank of the Ebro, 22 miles from its mouth, and 85 S.W. of Barcelona by rail. It manufactures cottons, linens, glass, soap, pottery, &c., and has sturgeon and lamprey fisheries. The Ebro is here crossed by a floating bridge, and T. is defended by three forts. Pop. 20,600.

Tortu'gas (Sp. *tortuga*, 'a tortoise'), or **Dry Tortugas**, a group of ten islets or keys, belonging to Florida, U.S., 40 miles W. of the most westerly of the Florida Keys. They are of coral formation, low, barren, and partly covered with mangroves. On Loggerhead Key stands a brick lighthouse 150 feet high, with a fixed white dioptric light of the first order. At Dry Tortugas Harbour a smaller light stands inside Fort Jefferson, an important fortification on Grand Key. The islets served as a place of imprisonment for persons under sentence by courts-martial during the Civil War, and for several criminals concerned in the murder of President Lincoln.

Tor'ture (Lat. *torqueo*, 'I twist'), in the republics of Athens and Rome, could only be inflicted on slaves, whose evidence otherwise was inadmissible; but by the Roman emperors it was extended to freemen—even senators and equites—and thus became a recognised part of Justinian's code. Thence in the Middle Ages it was employed by nearly every European state; in England being reluctantly adopted by Edward II. against the Templars (1310). Introduced under Henry VI. by the Duke of Exeter, the Rack (q. v.) was frequently applied to supposed witches, and to both Marian and Elizabethan sufferers for conscience' sake; the last instance of its use was in 1640, when one Archer was racked for attacking the archbishop's palace. T., however, except in the case of the Peine Forte et Dure (q. v.), was never more than a Crown prerogative, and was not formally recognised by English law, as was the Boot (q. v.) by Scotch. Upon the Continent it was for many centuries employed against criminals and political offenders by the various states, by the Church, and especially the Inquisition (q. v.), against heretics. It continued in use down to the close of last century, being abolished in France (1789), Germany (1754), Austria (1776), Sweden (1786), &c.; but such abolition was not always effectual, since in Hungary forty-eight gipsies were racked till they admitted a wholly unfounded charge of cannibalism (1782), and even in this 19th c. Ferdinand VII. of Naples submitted his prisoners to the 'question.' See Howard, *State of Prisons* (new ed. 1780); Mittermaier, *Das Deutsche Strafverfahren* (4th ed. Heidel. 1847); and Jardine, *Reading on the Use of T. in England* (Lond. 1837).

To'ry. See WHIG and TORY.

Tot'nes, a market-town of Devon, on the navigable Dart, 23¾ miles N.W. of Plymouth by rail, is an ancient place, with 'rows,' like those of Chester, lining the older portions of its one main street. Two gateways, a Norman keep crowning a lofty mound, a quaint guildhall, and the Perpendicular church of St. Mary (1432; restored by Sir G. G. Scott, 1874), with a fine stone screen and noble tower, make up the chief antiquities of T. Other buildings are the Church Walk or exchange, assembly rooms, the market-house (1846), and a grammar-school (founded 1554), while on the 'Plains' near the river a granite obelisk was erected (1864) as a memorial to the Australian explorer Wells. T. publishes one weekly newspaper, and drives an important trade in agricultural products. Pop. (1871) 4073.

Tou'can (*Rhamphastos*), a genus of *Scansorial* birds, forming the type of a family (*Rhamphastidæ*) in which the bill is enormously developed. The mandibles are, however, hollow, and the substance of this great bill being largely composed of air-cells renders the structure much lighter than it would otherwise be. The tongue is very long, and has notched or serrated edges, while in some forms distinct side-processes may be developed. The nostrils are borne at the base of the bill, and the wings are short and rounded, and have their fifth quill longest. The tail is short and even, and the claws are strongly made. The T. inhabits S. America. The *Rhamphastos ariel* is the common species; it attains a length of two feet, the bill measuring about eight inches in length. The general colour is a deep black, the throat and cheeks are white, and the breast yellow. An orange ring surrounds the eye. The flight of the bird is quick and agile. It moves about among the trees by a series of skipping jumps. The voice is harsh; and the cry of one species, resembling the word 'Toucan,' has given origin to the name. The food consists chiefly of vegetable matters, but at the breeding season the T. eats large quantities of termites or white ants. A domesticated specimen has been known to eat mice and young birds. Numerous species have been described, the different forms exhibiting great variation in the colouring of the bill.

Touch, the most widely diffused of senses, through which we gain information respecting the common properties of the material world and its objects. All parts of the body endowed with common Sensibility (q. v.) are seats of this sense, and the nerves which confer upon parts the sense of T. are those which confer powers of ordinary sensation on the different parts of the body—these nerve-fibres arising from the *posterior roots* of the spinal nerves, and the sensory nerves arising from the brain (see NERVE). The sense of T. is subserved in various ways in lower life. In fishes the *lateral line* is the seat of this sense. In birds the *cere* is believed to be the most sensitive part of the body in respect of the exercise of this sense. In quadrupeds, the 'whiskers' in the lions and cats generally; or the general body-surface and wing-membrane, as in bats, may subserve this sense. In insects, crustaceans, centipedes, &c., the *antennæ* or feelers are the organs of T., whilst in spiders the *palpi* of the mouth represents the antennæ of the insect. The tentacles of the snails, whelks, and their neighbours; the 'arms' of cuttlefishes; the tentacles of sea-anemones, corals, zoophytes, &c.; and even the unspecialised but sensitive protoplasm of *Protozoa* (q. v): each and all exercise this sense in greater or less perfection. Even in plants this most widely-diffused sense is represented. The sensitive hairs on the leaves of *Dionæa* (q. v.), and the equally sensitive leaves of the *Mimosæ* or Sensitive Plants, illustrate the nature and prevalence of sensation in plant-life. The dictum of Goethe, that all the senses are but modifications of T., seems to rest on a philosophical basis, since material contact of light-rays with the eye, or of sound-waves with the ear, is necessary for the production of sensations of sight and hearing respectively. Modifications of the sense of T. are numerous. The sensation of heat, pricking, and other states exemplify such modifications. The sense of pressure indicates a slight exercise of the sense of T. over a relatively greater area, and at a great depth; that of pricking arises from an intense affection of nerves over a small extent and at a limited depth. It is alleged by some physiologists that common sensation and tactile or special sensibility are exercised by different nerves or sets of nerve-fibres. This is Sieveking's view, and also that of Schiff and Broun-Séquard. The conditions for the exercise of the sense of T. depend, amongst other things, upon the perfection of the cutaneous or skin-circulation. A benumbed finger is useless for touch. Nor must the force of habit and the influence of education be lost sight of in connection with the perfection of this sense. The phrase *tactus eruditus* bears a very succinct physiological meaning, as seen in the deft touch of the artist, the engraver, or in that of the surgeon and physician. There can be little doubt that acuteness of T. depends to a great extent upon the nervous supply of any given part of the body. The sense of T. is liable to physiological derangement, as well as to abnormal action. When the fore and middle fingers are crossed, and a marble rolled between them, the sensations which result are those of two marbles, not of one. And in the matter of *after-sensations*, this sense is capable of being vividly perpetuated by memory, the remembrance of a pain or of a pleasurable sensation being an every-day feature of human life.

Touch'stone, or **Lyd'ian Stone,** a siliceous rock or 'glinty slate' which has long been used as a test or 'touchstone' for gold, the purity of the metal being judged of from the streak which it leaves upon the stone.

Touch'wood is a soft, white substance into which wood is converted by the action of such fungi as *Polyporus squamosus.* It is easily ignited, and continues to burn for a long time like

tinder. When highly impregnated with the fungus-spawn, the mass has been observed to be luminous.

Toul, a fortified town of France, department of Meurthe-et-Moselle, on the left bank of the Moselle, 15 miles W. of Nancy by rail. Its chief buildings are the celebrated Gothic cathedral of St. Étienne (965-1496), and the part Gothic, part Romanesque, collegiate church of St. Genoult. T. manufactures lace, calicoes, tiles, fayence, and vinegar. Pop. (1876) 10,085. During the Franco-German war, T. surrendered after three days' bombardment, 23d September 1870.

Toulon', a French naval arsenal of the first class, department of Var, beautifully situated on a deep inlet of the Mediterranean, formed by the peninsula of Sépet, 40 miles S.E. of Marseille by rail. It is built at the foot of the Pharon Hills, which protect the city on the N., and are partly covered with fine forests. Defended by a strong citadel, girt with a double-bastioned wall, and surrounded by some twelve forts and redoubts, it is, next to Brest and Cherbourg, the principal naval station of France. The town is divided into old and new parts, the former quaint and dingy, the latter containing the public buildings erected by Louis XIV. and several spacious squares, as the Champs de Battaile, Puget, and St. Pierre. Among the chief buildings are the Hôtel de Ville with cariatides by Puget, the Hôtel de l'Intendance, the cathedral of St. Marie-Majeure, dating from the 11th c., but greatly altered, a naval hospital erected by Louis XIV., the hospital of St. Mandrier, on the Sépet, a public library of 15,000 vols. and 8500 MSS., and a handsome theatre. The Mourillon tower, built 1848, in six *étages*, commands a magnificent view. The Bagne for convicts, established by Colbert in 1682, was removed in 1872. The *port militaire*, one of the largest in Europe, comprises the old Darsa, formed under Henri IV., the new under Louis XIV., and the Darsa of Castigneau; three repairing docks and three arsenals—(1) the *arsenal maritime*, built by Vauban, with a general magazine, a cordage factory, a foundry, a naval museum, a park of artillery, and an armoury; (2) that of Castigneau (area 17 hectares), with bakeries, copper-works, forges, &c.; (3) that of Mourillon, with steam saw-mills, covered slips, and large fosses for the conservation of timber. The naval port, the equipment of which is singularly complete, and the cost of which amounted to upwards of 160 million francs, is separated from the roadstead by hollow bomb-proof moles, lined with batteries. A great number of the inhabitants (some 10,000) are employed in the arsenal works, and of recent years there has sprung up a considerable trade with Algeria. The *port marchand* was entered (1876) by 80 sea-going vessels of 15,173 tons, and by about 350 coasters, of 19,500 tons. T. has an agreeable climate; at its Jardin des Plantes palms grow in the open air. Pop. (1876) 70,509. T. is said to have been founded by a Roman soldier, Telo Martius, and was known as *Telo* in the 4th c. It was destroyed by the Arabs in 889, and again in the 12th c., but in the 16th c. it had become a stronghold of some importance. On 27th August 1793 it was taken by the English, who were forced on 19th December following to surrender it to the Republicans after firing the shipping. Napoleon, a simple officer of the *Hommes sans peur*, then first evinced his genius for war.

Toulouse', an important city of France, capital of Haute-Garonne, in a broad, fertile plain, on the right bank of the Garonne, at the junction of the canals Du Midi and De Brienne, and the Canal-Lateral, 160 miles S.E. of Bordeaux by rail. With its fine skies and superb southern prospect stretching away to the grand outline of the Pyrenees, the town as a whole has no great architectural character, although it contains many fine buildings, luxuriant gardens, shady boulevards, spacious quays, and stately bridges. Among its public resorts are the Places du Capitole, de St.-Georges, des Carmes, and the Jardin des Plantes; the promenades, Jardin, Royal, Allées St. Michel, St. Étienne des Zéphyrs, des Soupirs, and the Grand Allée, are so many green links in the Grand Rond or Boulingrin. A stone bridge of six arches, 810 feet long, dating from the 16th c., and a modern suspension bridge, give access to the important suburb of St. Cyprien, on the S. side of the river. The houses are mainly built of brick, and the streets, excepting those of St. Cyprien, are in great part narrow and irregular. Of the public buildings the chief are the cathedral of St. Étienne, containing tombs of the Counts of Toulouse; St. Servin, one of the best specimens of Romanesque architecture in France, completed in the 15th c., with tower 63 metres high; the church Du Taur, of 13th c., with curious brick façade; the 13th c. Capitole, or town-hall, with its *avant-corps* adorned with eight marble columns; the old battlemented Collége de St. Raymond; the church of La Dalbade, with a portal ornamented with delightful Renaissance *motifs*; the Hôpital St. Jacques, rebuilt in the 18th c.; the arsenal, in an *enclos* of the Chartreux; the modern Hôtel de Ville (1750-60), designed by Cammas, with grand sculptures; the Palais de Justice, in front of which stands a bronze statue of Cujas by Valois. The Musée, formerly an Augustinian convent, contains a unique collection of objects of the Stone Age, some 5000 medals, and splendid cabinets of pictures and sculpture (forty marble busts of Roman emperors). The Public Library has 60,000 vols. and 700 MSS. The seat of an archbishop, T. has faculties of Catholic theology, of law, of science, and of letters, an École des Beaux Arts, a music conservatory, an academie de *jeux-floreaux* ('floral-games,' after the Troubadour contests), and various learned societies. The manufactures, which are important, comprise woollens, cottons, machinery, farm implements, candles, oil, oilcloth, soap, paper, &c. Besides transmitting 2,000,000 hectolitres of grain yearly, it carries on a large trade, chiefly at four annual markets, in wine, timber, Pyrenees marble, pâtés de foi gras, truffles, &c. T. is also the seat of a court for Haute-Garonne, Tarn, Tarn-et-Garonne, and Ariège, as well as the residence of the commander of the 12th Army Corps, and 34th Division. There are here military schools, arsenals, powder-factories, &c. Pop. (1876) 131,642. Originally the capital of the powerful Volcæ Tectosages, the town became the 'Palladian' *Tolosa* of Provincia, and a place of literary celebrity under the Romans. It was the chief town of the West Goths (from 412 A.D.), and on the division of the empire (817) fell into the hands of counts, who shook off their fealty about a century later. The 'county of T.' extended along the Garonne. T. was a celebrated seat of the Troubadours, and suffered severely in the fierce crusades which Simon de Montfort headed against the Albigenses (q. v.). The Parliament of T., though little known now except by the vile Calas (q. v.) decision, had a great reputation in its day. T. has frequently suffered by the floods of the Garonne, on the melting of the snow in the Pyrenees and Cevennes, but perhaps never more terribly than by those of June 1875. The rushing torrent swept away bridges, tore up railways, bore along houses, wrecked the suburb of St. Cyprien, drowned 300 souls, and left the plains of Garonne a desert. The loss was estimated officially at £4,000,000, but the total loss, direct and indirect, did not amount to less than £12,000,000. See Jourdan, *Panorama Historique de T.* (2d ed. Toul. 1877).

Toungu', the chief town of the district of the same name in British Burmah, on the right bank of the Sittang river, down which it exports timber and rice. Pop. (1872) 10,195. It was the capital of the Pegu dynasty, which attained great power in the 16th c.; and was chosen in 1858 for the exile of Behaudur Shah, the banished Mogul Emperor of Delhi, and is still the residence of his son.—The *district* of T. lies on the frontier N. of Rangoon and E. of Prome. Area 6354 sq. miles; pop. (1872) 86,166. It is the home of the aboriginal tribe of Karens (q. v.).

Tour'aco (*Turacus*), a genus of African birds belonging to the *Conirostral* division of the *Insessores* or perchers. The T. is allied to the plantain-eater, and has a short bill, the fourth, fifth, sixth, and seventh quills being longer than the others. The White-Crested T. (*Turacus albocristatus*) is the best-known form. It attains the size of a crow, is olive-green on its upper parts, the prominent crest being green with a white edge. The T. is wary and inquisitive. It inhabits trees, and runs quickly amongst the branches.

Touraine', a former province of France, bounded by Orléanais, Berri, Poitou, and Anjou, and now included in the department of Indre-et-Loire and a part of Vienne. It was celebrated for its fertility and known as the 'garden of France.' Since 941 it formed a separate countship, and fell in 1045 to the Counts of Anjou, next to the Plantagenets, and in 1203 to the French crown under Philippe II., Auguste. In 1360 it was made a duchy, and was granted to various French princes, but in 1584, on the death of Duke François d'Alençon, brother of Henri III., it was again united to the Crown. See Bourasse, *La T., son Histoire et ses Monuments* (Tours. 1855).

Tourcoing', a town of France, department of Nord, 3 miles from the Belgian town of Mouscron, and 6¾ miles N.E. of Lille by rail. It has factories for wool, cotton, flax, and silk spinning,

besides wool-combing and weaving, dyeing and sugar-refining. Upholstery wares, machinery, soap, and cutlery are also manufactured. Pop. (1876) 48,634.

Tour'maline, a mineral species, named from Tourmali in Ceylon, whence one of its precious varieties was first brought to Europe. It crystallises in rhombohedra, and it is also obtained compact and in columnar form. In composition and appearance T. is a variable and complex mineral, consisting principally of a compound silicate and borate of alumina and magnesia, but containing frequently iron, lithia, and other substances. Opaque kinds are generally distinguished as schorl, and the transparent varieties include various well-known jewellery stones, as the Brazilian sapphire, a deep-blue transparent stone; the Brazilian emerald or peridot, green and transparent; and the Ceylon peridot, of a honey-yellow colour. T. possesses powerful electric properties.

Tour'nament or **Tour'ney** (Fr. *tournoi*, from *tournoyer*, 'to wheel'), a trial of arms in which two mounted knights or bands of knights contended, ordinarily with blunted weapons, for the meed of valour. Traditionally invented by Geoffroy de Prenilly in the 10th c., these mimic combats of shivered lances and broken bones, spread in the teeth of clerical censure to most of the courts of Western Europe, reaching their zenith in the 14th c. Thenceforth they declined with waning chivalry, and after the accidental death of Henri II. of France (1559) were generally abandoned. Scott, glowingly describing them in *Ivanhoe*, suggested their revival (1839), but the elements fought against the Earl of Eglinton, umbrella and mackintosh assorting ill with casque and helmet.

Tour'nay (Flem. *Doornick*), a town of Belgium, in the province of Hainault, lies on both sides of the Scheldt, 15 miles E. of Lille by rail. Till lately fortified, it is modern in aspect, but has a Romanesque cathedral dating from the 12th c., and restored since 1852, with five great towers, rich painted glass, and pictures by Rubens and Jordaens. Other buildings are the churches of St. Jacques, St. Quentin, and St. Brice (containing Childerich's grave), the Belfry (1190; restored 1852), an hôtel-de-ville, athenæum, public library, museum, and five hospitals. T. has important manufactures of linen, woollen, and cotton stuffs, of carpets, porcelain, &c., and carries on a considerable river trade. Pop. (1878) 32,180. The *Tornacum* or *Turnis Nerviorum* of the Romans, T. was the seat of the Merwig monarchy, from Flanders passed to Philippe le Bel, and was ceded by France to Spain (1526). The Princess Marie of Espinay, whose statue (1863) adorns the Grand Place, defended it bravely against Parma (1581); and T. was again held by the French (1667-1709; and 1745-48).

Tourne'fort, Joseph Pitton de, a celebrated French botanist, was born at Aix, in Provençe, June 5, 1656. On the death of his father (1677), who intended him for the Church, T. turned all his energies to the study of natural history, and made a large collection of the flora of the country around Aix—a collection which ultimately came into the possession of the Paris Museum of Natural History. In 1683 he was appointed professor of botany at the Jardin Royal des Plantes. He subsequently made numerous journeys to Spain, Portugal, England, Holland, &c.; and in 1702 returned from an extended tour in Greece, Asia Minor, Armenia, and the Archipelago. His remaining years were occupied as director of the Jardin des Plantes, and professor of medicine at the Collège de France. He died at Paris, December 28, 1708. T.'s chief works are *Eléments de Botanique* (3 vols. 1694), written also in Latin; *Histoire des Plantes qui naissent aux Environs de Paris* (1698); *Relation d'un Voyage du Levant* (2 vols. 1717), and a *Traité de la Matière Médicale*, published posthumously by Besnier (2 vols. 1717), besides papers in the *Mémoires* of the Academy of Sciences.

Tour'neur, Tour'nour, or **Tur'ner, Cyril**, an English dramatist, who flourished in the latter end of Elizabeth's reign and the beginning of James I. The investigations of his most recent editor, J. C. Collins, have added almost nothing to the almost nothing that was previously known about his life. From a letter of Robert Daborne to Philip Henslowe, June 5, 1613, it appears that he was about that time employed as a playwright; but that is perhaps the only fact of his life that has been preserved. His works are as follows:—*The Transformed Metamorphosis* (1600); *The Revenger's Tragedy, or The Loyal Brother* (1607); *Funeral Poem on the Death of Sir Henry Vere* (1609); *The Atheist's Tragedy, or The Honest Man's Revenge* (1611), and a *Griefe on the Death of Prince Henrie* (1613). Another little book, *Laugh and Lie Down, or the World's Folly* (1605), being a prose allegory describing the Fool of Folly, with ballads interspersed, has been erroneously ascribed to him; and a MS. containing the tragic comedy of *The Nobleman*, undoubtedly from his pen, is known to have been burned by Warburton's servant in 1815. It is to his *Revenger's Tragedy* that T. owes the admiration of such men as Lamb, Hazlitt, and Swinburne; the first emphasises his realism, the second speaks of his 'dazzling fence of impassioned argument,' and the third is charmed by the 'bitter ardour and angry beauty of his verse.' In none of the other poems does he approach the same excellence, but in most there is a touch or two of his finer spirit. The *Transformed Metamorphosis* was written at leisure moments in three weeks, but its purely verbal obscurities would require the labour of a school of commentators for their complete elucidation. The only known copy of the original was discovered in 1872 by Mr. Charles Edmonds at Lamport Hall, in Hampshire. See *The Plays and Poems of C. T.*, edited by John Churton Collins (2 vols. Lond. 1878).

Tour'niquet, The, is an instrument used by surgeons for restraining hæmorrhage in amputations and other operations on the limbs. The common T. consists of a pad which is pressed down by a screw, attached by a large strap which encircles the limb, and thus as the screw is pressed down it tightens the strap, and makes pressure equally on the limb all round. In applying the T. care should be taken to direct the pressure so as to compress the artery against the subjacent bone. The Italian, Signorini's, or the horse-shoe T., is an arch of metal, larger than the limb, having an expanded piece to rest against the side opposite to the artery, while a screw carrying a pad is directed against the artery from the opposite side of the arch. The Italian T. has the advantage over the common T. in that it makes no circular compression of the limb, and produces a less amount of venous congestion. All the aneurism compressors, as well as the aortic T. for amputation at the hip, are made on this principle. The T. is now to a considerable extent superseded by the application of an elastic bandage, as recommended by Professor Esmarck, by which the limb is rendered bloodless. To prevent the return of blood a stout piece of elastic tubing is passed twice round the limb just below the upper end of the bandage, and secured by hooks. The bandage is then uncovered from the limb, which is perfectly bloodless. When the operation is concluded, and after the constricting band is removed, a few minutes should be allowed for the bleeding to subside under the use of cold water, after the main vessels have been tied.

Tours, a fine old town of France, capital of the department of Indre-et-Loire and of the former province of Touraine, on the left bank of the Loire, 145½ miles S.W. of Paris by rail. The river is crossed by two suspension bridges and by a stone bridge of 15 arches, one of the finest in Europe (1424 feet long, 48 feet broad), from which the principal street runs diagonally across the town, dividing it into two almost equal parts. The well-planted and extensive boulevards which surround the town, and the beauty of the banks of the river, with the regularity of the streets and the striking character of many of the buildings, combine to render T. one of the most agreeable towns of France. The finest buildings are the Gothic cathedral, St. Gatien (1170-1547), with a noble tower and fine stained windows; St. Julien's Church, the Palais du Justice, and the Hôtel de Ville. Interesting ruins are those of the abbeys of St. Martin-de-Tours, and Marmoûtier, and the Tour de Guise, the only remnant of the castle of the counts of T. T. has a library of 40,000 vols., a museum and picture-gallery, a botanical garden, a lyceum, a school of medicine and pharmacy, and several learned and benevolent associations. Active manufactures of woollen, cotton, and silk stuffs, tapestry, pottery, and porcelain, chemicals, leather, wax, and hardware are carried on. The silk fabrics of T. (*Gros de T.*) were once widely celebrated, but the revocation of the Edict de Nantes in 1685 drove the Huguenot workmen to Holland and England and ruined the prosperity of the town, reducing its population from 80,000 to 30,000. Pop. (1876) 48,325. T., called by the Romans *Cæsarodunum*, was the capital of the Gallic Turones, from whom it subsequently took the name of *Turoni*. Near it, in 732, Karl Martell and his

Franks won the decisive battle which saved Christendom and turned the tide of Arab conquest. The town was in 1503 under Henri III. the seat of the parliament, and in the late Franco-German War, after the investiture of Paris, it was the seat of the Government of National Defence. It was taken by the invaders January 19, 1871. See Giraudet, *Histoire de T.* (Par. 1873).

Tour'ville, Anne Hilarion de Cotentin, Comte de, a famous French admiral, born at Tourville, La Manche, November 24, 1642. He joined the Maltese Order in 1656, and in 1660 entered the French navy, of which he became a captain in 1667, and commanded a ship of the line in the Mediterranean during the war with the Dutch and Spaniards (1672-74). In 1675 T. served first under the Chevalier de Balbette, then under Duquesne; and on the return from Agosta, where he fought with distinction, he destroyed 12 ships of the Dutch-Spanish fleet at Palermo (1677). He was appointed lieutenant-general of the navy (1680), and bombarded Algiers three times (1682, 1683, and 1688). Vice-admiral of the Levant in 1689, he commanded in 1690 the fleet that supported James II. in Ireland; and in command of the French channel fleet defeated the Dutch and English fleets (112 sail) at the Isle of Wight in July 1690. In order to facilitate the landing of the Jacobites on the English coast, he was ordered to attack with 44 ships the British and Dutch fleets under Admiral Russell at Cape de la Hogue, and was defeated. In 1693 he was made Marshal of France, and in 1694, meeting an English and Dutch trading fleet, he took 27 vessels and destroyed 4 in the pursuit. He died at Paris, May 28, 1701. See Richer, *Vie de T.* (Par. 1783); and Maureix, *Théorie du Maréchal de T.* (Par. 1878).

Touss'aint, Anna Luize Geertruide, a popular Dutch novelist, was born September 16, 1812, at Alkmaar, and married in 1851 to the painter Bosboom. In 1837 she published her first novel, *Almagro*, which was followed by *De Graaf van Devonshire* (1838) and *De Engelsche in Rom* (1840). Her greatest historical works are the historical novels *Het Huis Lauernesse* (2 vols. 1841), placed in the Reformation period, which has been translated into several languages; *Leycester en Nederland*, *De vrouwem van het Leycester' sche Tijdperk*, and *Gideon Florenz* (the last three forming 9 vols. 1851-54).

Touss'aint, François Dominique, surnamed **L'Ouverture,** was born at Breda, Hayti, in 1743, of slave parents of pure negro blood, and availed himself of the insurrection of the slaves in 1791 to become ruler of the entire island, January 1801 (see HAYTI). He was subsequently treacherously arrested with the connivance if not by the orders of the French general Leclerc and conveyed to France, where he died at the castle of Joux (dep. Doubs) of ill-treatment, April 27, 1803. In character T. seems to have been merciful, and by no means destitute of noble emotions; of his military and administrative talents there can be no doubt. He is the hero of Miss Martineau's novel, *The Hour and the Man* (1839). Various Memoirs of T. have appeared, the latest of which is by Gragnon-Lacoste (Par. 1877).

Tower of London, The, the most ancient, and historically the most interesting pile in the English metropolis, is a mass of buildings on the N. side of the Thames, immediately to the E. of the ancient city walls, its ramparts and gates surrounded by a dry ditch in pentagonal shape, in outer circuit measuring 1050 yards. Within this the whole of the buildings are encircled by a double line of walls and bulwarks, in some places 40 feet high and 12 feet thick; the space between the walls being known as the outer ward, and the interior as the inner ward. The inner ward was formerly the royal quarter. The outer ward was the folk's quarter. The inner ward is defended by 12 massive and conspicuous towers, stationed at unequal distances, and possessing distinctive names and formations. In the centre, rearing its head proudly above them all, stands the main quadrangular building and great Norman keep known as the White Tower. To the N. are the barracks, and to the N.W. the church of St. Peter ad Vincula. The entrance to the buildings is on the western side by the Lion's Gate.

Tradition ascribes the origin of the Tower to Julius Cæsar. The White Tower was reared by William the Conqueror, probably as a secure place of shelter for himself and a menace to the turbulent citizens. It was designed by Gundulph, Bishop of Rochester, and bears a sister likeness to Rochester Castle. It is in three stories, is 116 feet long, 96 feet wide, and 92 feet high. Gundulph also designed the original church of St. Peter's, a finer building than that reared in its place when it crumbled into ruin in the reign of Edward I. Henry III., who left so many epics in stone to attest his architectural genius, spent much of his life and treasure in adding to the splendour of the Tower. He enriched it with frescoes and sculptures, with marble shafts and delicate traceries. Traitor's Gate was built by him, the noble arch under which so many noble heads passed to their doom. Wren refaced the White Tower and modernised its windows, but its interior still bears the splendid stamp of its grand antiquity.

For centuries the Tower was a palace, a prison, a fortress, and a court of law. Here the Plantagenet kings held their gay tournaments, magnificent revels, and pompous religious ceremonials. Here also tragedy succeeded tragedy, and the innocent blood of many of England's bravest and beautifulest poured forth in a cruel stream. Wise statesmen, fair queens, child-princes, noble warriors and priests were slain, their only crimes in many cases being their rank, their patriotism, and their faith. 'No sadder spot on earth,' says Macaulay, 'in England . . . . . Death is there associated . . . . . with whatever is darkest in human nature and in human destiny, with the savage triumph of implacable enemies, with the inconstancy, the ingratitude, the cowardice of friends, with all the miseries of fallen greatness and of blighted fame.'

The first state prisoner was Flambard, Bishop of Durham, who effected his escape in 1100 and fled to Normandy. The noble Wallace suffered a cruel imprisonment and terrible death here in 1305. The good Lord Cobham's story and fate are associated with the Beauchamp Tower. Charles, Duke of Orleans, imprisoned in the Banqueting Hall for a quarter of a century by Henry V., commemorated there his dead wife in touching verse. A volume of his poems in the British Museum contains the earliest known representation of the Tower. Richard, Duke of Gloucester, haunts the pile like a spectre. He murdered Henry VI. in the Hall Tower. The infant princes, his nephews, were smothered in the Bloody Tower; their supposed remains, found in the reign of Charles II., now lie in Westminster Abbey. Clarence, according to tradition, was drowned by Richard in wine in the Bowyer Tower, and Hastings condemned to death in the Council Chamber. The remains of King Henry VIII.'s beheaded queens, Anne Boleyn and Katherine Howard, lie in St. Peter's Church. A group of ghastly executions are associated with the reign of Mary, prominent among which are those of Lady Jane Grey, the wise, fair, and pious 'Twelfth Day queen,' her consort Dudley, and her father-in-law Northumberland. Imprisoned together in the Garden Tower, Cranmer, Ridley, and Latimer searched the New Testament together. Sir Walter Raleigh was thrice confined in the Tower which bears his name in many places. Here he wrote his *History of the World*, and beguiled his solitude with chemical experiments. Sir T. Overbury was poisoned in the Tower in 1613, and Strafford was beheaded in 1641, Laud in 1645. The last of the numerous executions in the Tower, but a few of which have been mentioned, was that of Lord Lovat in 1747. Among notable persons imprisoned here were Algernon Sydney, Lord William Russell, the Seven Bishops, the Duke of Marlborough, Sir Robert Walpole, John Wilkes, Lord George Gordon, and Sir F. Burdett. Arthur Thistlewood, in 1820, was the last state prisoner.

The public are admitted to the Tower on Mondays and Saturdays gratis, and on other days on payment of 6d. to see the Armoury and White Tower, and 6d. to see the crown jewels. The government of the Tower is vested in the Constable, usually an officer of high military rank. Strangers are shown over the buildings by the warders or beefeaters. The Records and the Mint, now removed, were for a long time established in the Tower, which is now a great ordnance store and depository of valuables. In the White Tower is the 'Chapel of St. John,' which formerly held the records, one of the finest specimens of Early Norman style. The Banqueting Hall and Council Chamber adjoining is used as an armoury, and is filled with 60,000 stand of arms, kept in perfect order and beautifully arranged. On the south side of the White Tower there are some interesting specimens of early gunnery. The Beauchamp Tower, which was restored in 1853 by Mr. Salvin, is to the west, and the Horse Armoury to the south. The latter, built in 1826, contains a gallery 150 feet long by 33 feet wide, in which are twenty-two

equestrian figures clothed in the distinctive armour of the reigns from Edward I. to James II. A staircase from the Horse Armoury leads to an antechamber filled with weapons and trophies taken in our struggles in the East. Queen Elizabeth's Armoury in the White Tower contains arms and armour of her reign, various instruments of torture, the beheading axe said to have been used in the execution of the Earl of Essex, and the block on which Lord Lovat was beheaded. The Jewel House contains several crowns, including that made for the coronation of Queen Victoria (valued at £111,900), the Kohinoor Diamond, and the diadems, sceptres, and jewels constituting the Regalia. The Wellington Barracks, a large castellated building on the north side of the West Tower, were erected in 1845, on the site of the Grand Storehouse built by William III., which was, along with 280,000 stand of muskets contained in it, destroyed by fire in 1841. To the north-west of the Tower is Tower Hill, the dire spot where, till within 150 years ago, stood the scaffold for the execution of traitors.

See *Historical Memorials of the T. of L.*, by Lord de Ros (1866-67), *Her Majesty's Tower*, by W. Hepworth Dixon (6th ed. 1871), and *Notice of Historic Persons buried in the Chapel of St. Peter ad Vincula*, by D. C. Bell (Lond. 1877).

Town-Clerk' is the clerk to a municipal corporation. He keeps the records of the borough, and takes charge of the voting papers at municipal elections. He is paid from the borough funds, and is elected by the Town-Council (q. v.). In England the town-clerk's tenure of office depends on the will of the council; in Scotland it is *ad vitam aut culpam*. In the latter country he is bound to give extracts from the records without reference to the town-council, and he is personally liable for any failure of duty.

Town-Coun'cil. See BURGESS; CORPORATIONS; MUNICIPALITY.

Town-Ma'jor, Town-Ad'jutant, officers holding the rank of captain and lieutenant respectively, who regulate garrison details and duties, such as the supervision of guards, military police, paroles, the roster of officers for garrison duty, the issue of garrison orders, &c.

Town'shend, Charles, an English statesman, born at Rainham, Norfolk, 10th March 1674, in 1687 succeeded his father as second Viscount T., and took his seat as a Whig in the Upper House (1695). Having acted as a commissioner for arranging the Scottish Union (1706), he was joint-plenipotentiary with Marlborough in the unsuccessful negotiations at Gertruydenburg (1709), and next as Ambassador to the States-General signed the Barrier Treaty. For this he was censured by the House of Commons, and declared an enemy to Queen and kingdom—a disgrace which led him warmly to espouse the Hanoverian succession. Accordingly, under George I. he was head of the administration from 1714 to 1716 as Secretary of State, which office he resumed in 1721. This time, however, he shared his power with his brother-in-law, Walpole (q. v.), a quarrel with whom was followed by P.'s resignation and withdrawal to Rainham, where he died 21st June 1738. Generous but overbearing, rough and impetuous but of spotless honour, T. deserves to be remembered, if only for the introduction of the turnip to his native county. See the Histories of Stanhope (1853) and Lecky (1878).

Town'shend, Charles, grandson of the above, was born 29th August 1725, and entering Parliament in 1747 as an adherent of the Pelham government, was created a commissioner of trade and plantations (1759). Having made a name by his speech against the Marriage Bill (1753), he became a lord of the Admiralty (1754), a member of the Privy Council (1756), secretary of war (1761-63), first lord of trade and plantations (1763), and paymaster of the forces (1765). He 'had belonged,' says Macaulay, 'to every party and cared for none,' and now in 1766 he accepted the chancellorship of the exchequer in Chatham's Ministry, together with the leadership of the House of Commons. Stirred by a taunt from Grenville, T. introduced and carried the Colonial Importation Bill, the cause of the War of American Independence, but he did not live to see its issue, dying suddenly within three months, 4th September 1767. More popular than Pitt, by Macaulay styled 'the most brilliant and versatile of mankind,' by Burke 'the delight and ornament of the House of Commons,' the 'Weathercock' is now remembered but by his witty sayings, many of which are recorded in the Life of him by Percy Fitzgerald (1866). See also vol. iv. of Bancroft's *History of America* (new ed. 1876).

Town'ship, in English law, is a division of a parish with a constable of its own.

Toxicol'ogy (Gr. 'the science of poisons') is the term commonly employed in medical jurisprudence to designate the science of Poisons (q. v.). T. embraces a consideration of all known poisonous substances, their physical and physiological properties, the post-mortem results which they occasion, and the modes by which they may be detected by chemical re-agents, and microscopic and other modes of examination.

Toxoc'eras (Gr. 'bow-horn'), a genus of extinct *Cephalopoda* (q. v.) or cuttlefishes belonging to the family *Ammonitidæ*, and having a bow-shaped or armate shell. Species of T. occur in rocks ranging from the Lower Oolites to the Gault. The most typical development is found in the Cretaceous rocks.

Tox'odon (Gr. 'bow-toothed'), an extinct genus of Mammals forming the type of the order *Toxodontia*, the remains of which are found in recent deposits in S. America. The Toxodonts, of which only two genera (*Toxodon* and *Mesodon*) are known, present a singular combination of the characters of Ungulata (q. v.), Rodentia (q. v.), and Edentata (q. v.). The skull is large, and the molar and premolar teeth are strongly bent or folded. These teeth were rootless, and grew from permanent pulps. The lower jaw had small canine teeth, occurring, like the canines of the horse, between the incisors and premolars. No traces of limbs have been found in a fossil state.

Toys are chiefly manufactured in Germany and France, whence they are exported to all civilised quarters of the globe; and in Switzerland, England, and the United States, toy-making is also an important and expanding industry. The materials used are very numerous and varied, and the processes by which the T. are manufactured are frequently clever and interesting. Nürnberg, formerly the toy-emporium of Germany, manufactures large quantities of wood and metal T.; Sonneburg and neighbouring villages produce an abundance of playthings in wood and papier-maché; Marburg in Hessen has a specialty in musical T.; and Biberach in Würtemberg is famed for its substantial and nicely painted metal articles, including carriages, locomotives, furniture, &c. Wooden T. are to a large extent fashioned on the lathe. In Saxony an ingenious process is pursued in the production of figures of animals. A circular block of soft wood is turned into a ring of such a pattern that by slicing it vertically a rough representation of an animal (say an elephant) is secured. The size of the ring depends upon the required size of the animal. Each rudimentary figure is then trimmed by hand, the ears, trunk, tusks, and tail (all separately turned by a similar process) are inserted, and the elephant is finished by being painted and varnished. T. in papier-maché and other compositions are formed in carefully made moulds of plaster-of-Paris and sulphur, and are subsequently painted. Durability and cheapness are the distinguishing qualities of German T. The playthings of French production, on the other hand, are celebrated for their artistic merit and attractiveness; and the French doll, owing to its beautifully modelled head of porcelain, articulated body, and rich and tasteful *trousseau*, occupies the first rank. Ingenious and highly finished clockwork, musical and mechanical T., are also specialties of France. The Swiss excel in carved wood animals, châlets, &c. England's chief production in toy art is the wax doll, in which that country has no rival. The doll has a nicely modelled head of wax, with eyes of glass and luxuriant tresses. Inferior varieties of English dolls are known to the trade as 'composition' and 'rag' dolls. London also excels in the production of T. in glass, porcelain, stoneware, pewter, and other metals, as well as in ivory and common and choice woods; and there has lately been a remarkable development in the manufacture of T. in vulcanised indiarubber, vulcanite, &c. A small export trade in T. is carried on with India and the colonies; in 1877 it reached the amount of £33,235. We imported in the same year T. valued at £444,829 (£234,635 from Germany). The United States, which formerly drew all its supplies from Europe, now not only makes the most of its own T., but exports a great number of common kinds as well as of sensational T. of native invention. The export trade of 1877 amounted to over $1,000,000.

Tra'cery, in Gothic windows, the lace-like divergency of the mullions into circles, quatrefoils, and other geometrical figures (Early Decorated style), into flowing, elaborate forms (Late Decorated), and into a blending of curved and horizontal lines (Perpendicular).

Trach'ea (Gr. *trachys*, 'rough,' so called from the rough gristle of which it is composed), or **Windpipe**, the name given to the tube extending from the *Larynx* (q. v.) or organ of voice, and from the level of the fifth cervical vertebra to the third dorsal vertebra, at which latter point the T. bifurcates or divides into two main *bronchi* or divisions, one supplying each lung with air-tubes. The average length of the T. is 4½ inches, and its diameter about ⅘ths of an inch, the latter measurement being greater in males than in females. The T. consists of fibrous membranes united by elastic cartilaginous rings, rendering the tube flexible and patent. The cartilages are circular but imperfect rings, each being joined posteriorly by fibrous membrane. They vary from 16 to 20 in number. The *muscular fibres* of the T. are of *longitudinal* and *transverse* arrangement. The T. is lined with *mucous membrane*, the epithelium of which is ciliated. The T. receives blood from the *inferior thyroid arteries*, and nerves from the *pneumogastric* and *recurrent* trunks, and also from the *sympathetic system*. The *right bronchus*, or one of the main divisions of the T., is wider and shorter than the left. It enters the lung opposite the fourth dorsal vertebra. The left bronchus is smaller and more oblique than the right, and enters the left lung at the level of the fifth dorsal vertebra. Foreign bodies falling into the T. most frequently enter the right bronchus, because of the larger size of the latter, and because of the more oblique position of the left bronchus.

Diseases and Injuries of the T. The T. is liable to inflammation and its products, and frequently suffers from extension of disease from the larynx. *Acute inflammation* of the T. may occur as an idiopathic affection, or a symptom of other diseases, as smallpox, measles, typhus, tuberculosis, croup, &c. The symptoms are pain in the windpipe from the top of the sternum, expectoration of mucus, sometimes in regular rings, and a peculiar brazen-like cough. When confined to the larynx there is no hoarseness. *Chronic inflammation* of the T. usually accompanies follicular pharyngo-laryngitis, tuberculosis, and syphilis, and may extend to the submucous tissues and the cartilaginous structures, resulting in ulceration, cicatrisation, and stricture. The treatment consists in rest, the application of warm poultices, the inhalation of steam impregnated with balsamic or anodyne substances, and the administration of antiphlogistic remedies. Sulphate of zinc or nitrate of silver may be applied locally with the sponge probang, or the douche. *Constriction* of the trachea may be produced by aneurismal or other tumours pressing externally on the T.; or the symptoms may be produced by pressure on the nervous trunk, or the inferior laryngeal fibres. Constriction may also depend on undue muscular contraction, the seat thereof being immediately above the bifurcation of the T. *Foreign bodies* occasionally pass through the larynx into the T., and the accident is a formidable one, which not unfrequently proves fatal. The accident occurs most frequently among children, and is caused by a sudden inhalation while holding something in the mouth. Occasionally, however, a foreign body may, during the act of swallowing and without an inhalation, pass under the epiglottis and into the upper part of the larynx. Foreign bodies in the windpipe may be arrested above the rima glottidis, between the vocal cords, in the cavity of the larynx, or in the T. In such cases the patient is suddenly seized with convulsive cough and dyspnœa. The speech is more or less affected, and the breathing is whistling or stridulous; but the diagnosis rests mainly on the sudden accession of the symptoms. When the presence of a foreign body is made out, it ought to be removed at once. When the body is loose in the T., a free opening lower down should be at once made, and the opening may be either longitudinal or transversely valvular. It is advisable in nearly all cases to open the T., as, by securing a free aperture for respiration, spasm of the glottis is obviated, and the foreign body may be removed through the artificial opening, or it may fall through the glottis into the mouth. *Fracture* of the T. occurs from direct violence, and in such cases the wounded part should be laid freely open, so as to secure the passage of air to the lungs. Union of the wound by suture is to be avoided, that by suppurative inflammation being preferable, the head and neck being retained in a suitable position. Foreign bodies in the T., and all kinds of injury from external violence, are serious affections, as disease of the lungs is apt to be induced.

Tracheot'omy. The windpipe may be opened in three different positions, viz., between the cricoid and thyroid cartilages, above the thyroid isthmus, and below it, and all three operations are often termed T. The operation, through the crico-thyroid interval, is properly termed *laryngotomy*, that above the thyroid isthmus *laryngo-T.*, and that below the thyroid isthmus, T. The operation is performed as follows:—An incision is made in the middle line, from an inch and a half to two inches, downwards from the cricoid cartilage through the skin and deep fascia. Any arteries wounded in this incision being secured, the subcutaneous connective tissue is divided, fold after fold, the large vessels being pressed aside or ligatured when required. The sterno-hyoid and sterno-thyroid muscles are then separated by the handle of the knife, exposing the upper portion of the trachea, which is usually covered by the isthmus of the thyroid gland, which may be drawn up with a hook if it is unusually broad. The trachea should be carefully dissected until three rings are exposed. A sharp tenaculum is then thrust into it, and it is raised somewhat upwards and steadied, and then divided from below upwards by a sharp-pointed bistoury inserted into one of the interspaces. The completion of the operation is confirmed by the peculiar hissing sound with which the air rushes out of the open wound. The next step is the introduction of the canula, which soon becomes obstructed with mucus, and the inner tube must often be withdrawn for the purpose of cleansing it. The canula must be secured by a piece of tape round the neck, and the edges of the wound above and below the canula may be brought together by stitches or by adhesive plaster. The room in which the patient is confined should be kept warm at a temperature of not less than 80° F., and more or less of an atmosphere loaded with steam should be secured by some means. T. may be necessary in cases of disease or injury which produce mechanical impediment to the passage of air from the mouth into the trachea, in cases of foreign substances in the air passages, and in some cases of suspended animation where artificial inflation of the lungs cannot be performed by the ordinary means.

Trach'yte (Gr. *trachys*, 'rough'), a generic term applied to certain felspathic rocks, on account of the harsh, gritty feeling which many of them present to the touch. The felspar seems invariably one of those varieties which are richest in silica, and along with it are frequently disseminated such minerals as mica, quartz, and hornblende. *Obsidian* and *Pitchstone* have been demonstrated experimentally to consist of fused and vitrified trachytic rocks. *Pearlstone* is of similar origin, but is built up of numerous small grains or nodules aggregated together. *Clinkstone*, another trachytic rock, splits readily into laminæ, sometimes fine enough for roofing-slates, and owes its name to the clear ringing sound it emits when struck with the hammer.

Tra'cing-Paper is thin paper rendered translucent by brushing over it a mixture of turpentine and an oleo-resin, such as Canada balsam. A thin coating of the varnish is first applied, so as to permeate the paper, which is afterwards coated on both sides more thickly till an equal translucency is obtained. The paper should be kept warm during the operations, and thoroughly dried before use.

Tracta'rianism, the Romeward movement in the English Church, which dates, says its founder, John Henry Newman, from July 14, 1833, the Sunday when Keble preached upon the 'National Apostasy.' Its causes were twofold—the spirit, on one hand, of Romanticism turning men's minds to mediæval times; and, on the other, reaction from the great Liberal wave that swept away Catholic disabilities, threatened the wealth of the Established Church, and bore German rationalism over to England's shores. Something was wanted to stem this wave better than the quiescent Anglicanism in which bishops could doubt whether Apostolical Succession formed part of their creed or no; one needed positive dogma and belief in a Church founded like Rome upon antiquity, while free from Romish, *i.e.*, non-primitive, error. Antiquity! but where then draw the line—at apostolic, patristic, or pre-Tridentine times? Purity! did it consist in the rejection of transubstantiation, of mariolatry, or merely of papal infallibility? Such were the problems mooted by a small band of Oxford scholars—Newman (q. v.), the subtle Aristotelian, Pusey

(q. v.), whom Newman styled 'the Great,' Keble (q. v.), the gentle singer of the *Christian Year*, Faber (q. v.), as winning as easily won, Manning (q. v.), the after 'hierarch,' and Hurrell Froude, whose untimely death in 1836 arrested the foremost in the race to Rome. And such were the problems offered a wondering world in the ninety anonymous *Tracts for the Times* (1833-41), whence 'Anglo-Catholics' were dubbed Tractarians, and in which was discerned a steady approximation to the faith of Rome, due partly to their avowed economy or reserve (*disciplina arcani*), but more to the necessary albeit unconscious development of their starting principles—Apostolical Succession, a Real Presence, Baptismal Regeneration, Tradition, and the like. Those principles were not new; they could be backed by reference to writers of the school of Laud (q. v.), nay to the Prayer-Book's self, whose 'Calvinist Articles' even were capable, by Tract 90's showing, of Catholic interpretation. How 'comprehensive' is the English Church, has since been shown in the Gorham and Bennett judgments; but then, in 1841, the question was: Would Churchmen admit Tractarian teaching, whether such teaching were or were not the Church's own? The storm of indignation that greeted Tract 90 gave plainly the answer No! and by that answer T.'s doom was sealed. Two courses remained for Tractarians—one to go forth from a Church that pronounced their opinions heresy, the other to keep both offices and opinions in flat defiance of those 'Successors of the Apostles' whom they at ordination vowed to obey. The first course Newman chose, crossing the Rubicon—an insignificant stream—to Rome; the second Pusey, and with him many of the heavier troops—those burdened, namely, with wives and families. Yet these Epigoni have loitered by the brink, and, if not quite at Rome, copy from their near vantage-ground the doings of Rome with constantly-increasing skill. Their creed (*plus* Infallibility and *minus* the Right of Private Judgment) has been given already under ROMAN CATHOLIC CHURCH, so need not be given anew; its outward expression may be looked for indifferently in the *Priest's Prayer-Book* and *Directorium Anglicanum*, or in the *Missal* and *Garden of the Soul*. The truth or falsity of that creed *per se* far exceeds the narrow bounds of the Tractarian controversy, which should limit itself to the single point of the creed's application by Tractarians to the English Church—a proceeding Catholics might compare with the ascription of a king's healing touch to bastard Monmouth, Low Churchmen with the investiture of Philippe Egalité with the divine (but abdicated) right of kings. Few even of the hottest Protestants would deny to Cardinals Manning and Newman their present right to believe in transubstantiation; but Messrs. Denison, Tooth, Mackonochie, and Carter, the State-paid officers of an Established Church, in upholding doctrines repudiated by that Church at large, and by the State protested against in the Public Worship Regulation Act of 1874, seem to an ordinary looker-on to be breaking a contract, to be not unlike 'those perfidious statesmen of the 17th c. who, loaded by William with benefits, kept up a correspondence with exiled James.' They at least are satisfied with their position, as in a measure is the Roman Church; Pusey by Pio Nono being likened to 'the church-bell, which rings people into church, though it does not come in itself.' And even their fellow-Protestants may thank them for hastening on disestablishment, or for raising doubts that have shipwrecked Clough's and many another noble mind, or for the £25,548,703 expended, thanks to T., on 8871 cathedrals and churches in England and Wales during 1840-76. See Froude's *Remains* (4 vols. 1838-39); H. Rogers' *Essays* (1850); Newman's *Apologia* (1864); Pusey's *Eirenicon* (1865); Thirlwall's *Remains* (3 vols. 1875-76); and Coleridge's *Memoir of Keble* (new ed. 1874).

Trade, Board of. See BOARD OF TRADE.

Trade-Marks. The Trade-Marks Registration Act (1875) for the United Kingdom defines a trade-mark as a 'name of an individual or firm printed, impressed, or woven in some particular and distinctive manner, or a written signature of an individual or firm; or a distinctive device, mark, &c.; and there may be added to any one or more of the said particulars, any letters, words, or figures, or combination of letters, words, or figures,' the use of certain specified devices and words being excepted. The 'signs' belonging to tradesmen in the Middle Ages were heirlooms, but were gradually disused, until, from the development of international commerce, a 'sign' on goods for sale became a necessity. The piracy of such marks became itself a trade among unscrupulous and inferior tradesmen; and for this abuse there was no real redress in Great Britain till the passing of the Act of 1875. The purchaser had to submit to the imposture, and the real owner of the trade-mark alone could pursue the fraudulent dealer. The difficulty of proving priority in the use of T.-M. made it impossible that justice could protect the right of 'property' until this Act provided for the registration of T.-M., and the existence of a legal register open for examination. Registration is effected by formal application to the Registry Office, London. The total fees amount to about two guineas. Registration is not compulsory; but one whose trade-mark is not registered cannot criminally pursue another who has appropriated it, although the matter of priority in its use may be subject to judicial examination.

Frauds in T.-M. The laws relating to the fraudulent marking of merchandise were amended by statute in 1862. T.-M. are defined as including every name, letter, or device used by any one to distinguish his manufactures from those of others. Forging a trade-mark with intent to defraud, or to enable another to defraud, is a misdemeanour, the fraudulently-marked merchandise, with the instrument used in the forgery, being forfeited. 28 and 29 Vict. c. 119 enacts that if any trader falsely represents that he has obtained a medal or certificate from the Exhibition of 1851 Commissioners, on account of any article or group, he shall be liable for the first offence to a penalty of £5, and for a second to a penalty of £20. Penalties are summarily recoverable before two justices in England and Ireland, and in Scotland may be prosecuted before the sheriff or before two county justices. The Act affects no civil right of remedy. A false indication of quantity is punishable by law.

Trade-Protec'tion Soci'eties are associations formed by traders for mutual protection against losses in business transactions. They are supported by annual subscriptions of small amount, which are in effect insurances against fraud. At the offices of the societies, registers, for the use of members only, are kept, of frauds, bankrupts, known swindlers, changes of residences of debtors, &c.; while private circulars are disseminated containing confidential lists of bills of sale, judges' orders, warrants of attorney, cognovits, county-court judgments, lists of bankrupts, assignments, trust-deeds, and of any fraudulent proceedings by which trade generally or individual interests may be affected. The societies also give gratuitous legal advice in certain matters, and undertake to act through their solicitors as agents in the recovery of debts, and in investigations in bankruptcies on certain terms. The operations of the societies, if distasteful to dishonest persons, afford protection to deserving debtors, who, instead of being subjected to the expense of legal proceedings, are enabled to pay their debts by instalments. Information is given as to the propriety of giving credit to any person who has ordered goods from members. One of the largest of the metropolitan T.-P. S. is the London Association for the Protection of Trade, in Berners Street, which has branches at Exeter, Plymouth, and Brighton. During the last six years it has recovered for its members £635,000, and made inquiries affecting property to ten times that amount. Among the leading provincial associations are the Liverpool Guardian Society, the Northern Counties Association, the Scottish Trade-Protection Society of Edinburgh, and the Glasgow and West of Scotland Guardian Society. The associated societies are enabled to give valuable information in upwards of two thousand cities, towns, and villages throughout the United Kingdom.

Trades-Unions, organised voluntary combinations of workmen in particular branches of industry with the object of securing the most favourable conditions of labour.

In this country the earliest form of voluntary associations of men for mutual help and support were the Frith Guilds, which were recognised as responsible bodies by Alfred and Athelstane. In towns the different guilds often became unified the better to carry out their objects, and the terms citizen and guild-brother were sometimes identical. With the increase of wealth and population a more general division of labour between wholesale tradesmen and craftsmen gradually arose, and the craftsmen were latterly practically excluded from the guilds, which assumed the shape of mercantile oligarchies; consequently craft guilds were formed, the earliest being that of the weavers in the 12th c. At that time craftsmen were usually small masters, and there was no actual working class in the present meaning of the word. After the plague of 1348 wages were regulated by a statute,

which caused a revolution in the relations between labour and capital, and ranked them on opposing sides. Craft guilds declined and journeymen fraternities sprang up, led by the building trade, which in the large number of men employed and the few masters under whom they served most nearly resembled modern manufacturing concerns. The Statute of Apprentices, 5 Elizabeth, c. 4, codified the order existing for centuries among craft guilds, and applied it to all trades. By this Act every master or journeyman was obliged to serve an apprenticeship of seven years—the hours of labour were to be twelve hours in summer, and from day-dawn until night in winter, and wages were to be assessed yearly by justices of the peace. The woollen manufacture was for a long time the staple trade of England, and was regulated by this Act. But before 1720 the assessment of wages by the justices of the peace fell into disuse, and the absence of a fixed rate of wages led the workmen to combine. In 1756, when the workmen petitioned the justices to fix the rate, the masters objected, and the justices refused the petition. The workmen consequently revolted, and a strike on their part led to riots and to the masters agreeing to their demands. The justices were then ordered by 29 Geo. III. c. 33 to settle the rate of wages yearly, but the whole system was on the eve of a great change. The introduction of machinery substituted large mills and factories for small businesses, and manufacturers freely employed women and children in addition to journeymen and apprentices. T.-U. were then formed by the workmen to resist the action of employers of labour, and to maintain the independence of artisans and the consolidation of their order. Among the earliest combinations were those in the woollen trade, the shipwrights of Liverpool, the hatters, the tailors, the printers in London, and the ironfounders in Staffordshire. In 1824 a committee of the House of Commons was appointed to consider the laws relating to workmen, which resulted in the Act of 1824 (5 Geo. IV. c. 95), making certain combinations of workmen for the first time allowable. This statute was repealed and reproduced with some alterations next year in Act 6 Geo. IV. c. 129. The Court of Queen's Bench decided in 1867 that T.-U. had no right to hold property. This resulted in a Royal Commission being appointed to investigate the subject. By Russell Gurney's Act, 31 and 32 Vict. c. 116 (1869), the funds of the unions were for the first time protected by law, and this protection was further extended in 1871 by Act 34 and 35 Vict. c. 31, and in 1876 by Act 39 and 40 Vict. c. 22.

T.-U. are to a great extent banks for the relief of men out of work, although most societies offer advantages also in case of sickness, accidents, &c. The age of entrance for fully-qualified and voting members is usually fixed at not younger than 21, and members are elected personally by the members of the lodge or branch to which they belong. An entrance-fee is charged, and thereafter uniform weekly subscriptions of from 1s. to 2s., the accumulation of which forms the reserve-fund, to cover expenses of strikes, &c. Unions are managed by superintending or executive councils, annually elected by the members by ballot, and including a president, treasurer, and secretary. The books and accounts are audited by the members, and the salaries paid to officers are not large, varying for presidents from 1s. per meeting-night to £40 a year, and for treasurers from 1s. for each attendance to £20 a year. The highest salary paid in 1878 to an officer was £234 to the secretary of the great society of Amalgamated Engineers. The government of every society and all its decisions belong exclusively to the council. When funds are insufficient, a levy is made on the members. The larger and not merely local organisations are divided into a number of branches or lodges, who have their special funds and elect their own committees. In some unions the central council is composed of delegates elected by the various branches; in others, the committee of each branch acts in turn in that capacity. If any branch strikes without the sanction of the central authority, it loses the support of the union. The balance in hand of each branch is in certain unions carried every year to a common fund, while in others the branches exercise complete independence in financial matters, subject to the liability of contributing if necessary to the funds of any branch needing assistance. When members cease to subscribe they are expelled. All efforts at a national federation of T.-U. have hitherto failed. Annual congresses of delegates from T.-U. have been held in leading towns of Great Britain from the first at Manchester in 1868 to that at Bristol in 1878, the proceedings having always been open to the press and public.

The legality of these organisations could not be established unless they were purely voluntary, and coercion on their part is clearly a violation of the law. In 1866 attention was called to violence and outrages stated to be committed by T.-U. Commissions of inquiry in several towns failed to find the unions guilty, but at those held at Sheffield and Manchester, outrages were proved which thrilled the country with horror. In the former place two murders and fifteen attempts at personal violence, and in the latter a wholesale destruction of non-unionists' property, were proved. Among the most reprehensible practices which have existed in unions are those of *rattening* and *picketing*. Rattening is the taking away of a workman's tools who is in arrear with his contributions to the union. Picketing is watching works during a strike by pickets, who endeavour to dissuade men who are willing to work from doing so. Where argument is alone used it is legal, but where it is combined with hissing, jeering, and taunting, or with personal violence, it deserves severe punishment. Owing to increased facilities for disseminating information, picketing is yielding as a regular system. The class of workmen who take advantage of a strike to obtain high wages, with the intention of seeking employment elsewhere upon its termination, are known among unionists as the 'blacks.' Unionists often refuse to work with them, or to speak to them. A few unions have wished to fix a limit to the amount of work that each man is to be allowed to perform, and by establishing a uniformity of wages to bring all down to one dead level of mediocrity. But the spirit of emulation has not been extinguished by unions, and many of their members have risen to be masters.

The recognition of T.-U. by the legislature has abolished secret societies. For good or evil they are a great English social force, and their number and strength steadily increases. Sixteen of the leading unions in January 1877 had 2723 branches, 208,318 members, and an income of £377,722. Their expenditure was £333,142, and their funds in hand £603,065. The most important society was the Amalgamated Engineers, with 390 branches and 44,578 members. Next came the Boiler-Makers and Iron Shipbuilders, the Masons, the Amalgamated Carpenters, and the General Union of Carpenters. The Agricultural Labourers since the year 1872 have established three large separate unions. Many unions have newspapers. The total number of independent societies amounts to nearly 3000, with 1,250,000 workmen, and their total income to at least £2,000,000. Startling as those figures are, they do not adequately express the power of the unions. In case of need, vast numbers of workmen, not regular members, swell their ranks, and for all practical purposes they represent the flower of the artisan population. Though non-political in character, they have taken part in certain great movements, and they played a prominent part in the Reform Struggle of 1866–67.

(eleven in number), 1867–69; 'The Good and Evil of Trades-Unionism,' by Frederic Harrison (*Fortnightly Review*, January 1866); *The T.-U. of England*, by the Comte de Paris (translated by N. J. Senior, 1869); and *The Conflicts of Capital and Labour*, by G. Howell (1878). See also STRIKES.

Trade-Winds. See WINDS.

Tradu'cianism (Lat. *traducianismus*, from *tradux*, a 'vine-layer' for propagation) is the theory which maintains that the soul, as well as the body, of each human being is propagated by the parents. It holds that by the single act recorded in Gen. i. 27 all mankind were created complete, both as to their spiritual and material nature, in the first pair, from whom they have been individually procreated and born. This view of the origin of the soul was first distinctly stated by Tertullian (q. v.); founded chiefly on St. Paul's argument in Rom. v. 12–19 (*cf.* 1 Cor. xv. 32, Eph. ii. 3, Heb. vii. 10, Ps. li. 5, Gen. v. 3), and from his time onward gained ground in the Western Church from its affinity with the prevalent doctrine regarding original sin. Greatly established by Augustine, disowned by the Schoolmen, and partially revived among Calvinists and Lutherans, T. has received little attention for the last two centuries.

Trafal'gar, Cape, a Spanish headland on the Atlantic Ocean, near the Straits of Gibraltar, off which Lord Nelson (q. v.), with 31 ships, gained a memorable victory over the combined French and Spanish fleet, October 21, 1805.

Trag'acanth. See GUM.

Tra'gedy. See DRAMA.

Trag'opan (*Ceriornis*), a genus of *Rasorial* birds allied to the common fowls (*Gallinæ*), and inhabiting Tibet, Nepal, and the higher ranges of the Himalayas. The Horned T. (*Ceriornis Lathami*) is a familiar species, attaining the size of a large fowl. It is of a brown hue of varying shades and tints, speckled on the back with prominent white spots. The tarsi in the males are armed with 'blunt spurs,' and the head bears a prominent crest. The wattles of the males are very large and prominent. The tail is short and somewhat spare.

Train'-bands, a force partaking of the nature of both militia and volunteers, instituted by James I. in the place of the fyrd or general army of the population. It was dissolved by Charles II. The term was, however, applied to the London Militia, from whom the 3d Buffs were raised, till the middle of last century. John Gilpin, it will be recollected, was a 'train-band captain.'

Train'ing. The object of T. is to render the system of a person in good health capable of undergoing some unusual feat of exertion, and to increase the powers of endurance. By judicious T. 'a concordant action is established between the heart and blood-vessels, so that the strong action of the heart during exercise is met by a more perfect dilatation of the vessels, and there is no blockage of the flow of blood. In the lungs the blood not only passes more freely, but the amount of oxygen is increased, and the gradual improvement in breathing-power is well seen when horses are watched during T. This reciprocal action of heart and blood-vessels is the most important point in T.; the nutrition of nerves and muscular fibres improves from constant action and the abundant supply of food; the tissue changes are more active, and elimination, especially of carbon, increases. A higher condition of health ensues; and if not carried to excess, T. is simply another word for healthy and and vigorous living.' The rules that used to be laid down for making athletes were largely the product of crass ignorance and vulgar superstition. The restrictions in regard to the kinds of food and forms of exercise had no physiological warrant, and were little, if at all, better than quackery. The Englishman who has done most to abolish the absurdities and impostures connected with the subject is Mr. Maclaren, the teacher of gymnastics at Oxford, whose book, *T. in Theory and Practice* (Lond. 1866; 2d ed. 1874), is the standard authority on the subject. To it the reader is referred for details.

Train'ing Coll'eges, or **Nor'mal Schools**, institutions for the professional education of teachers, are widely distributed throughout Europe and the United States. The earliest establishment of the kind of which there is authentic record is the Institute of the Brothers of Christian Schools, founded in 1681 by the Abbé de la Salle, canon of the cathedral of Rheims. Little is known of its scope or action; but in 1697 August Hermann Francke founded in connection with his orphan school at Halle a 'teachers' class' of poor students, who assisted in the work of instruction in return for board and lodging. From this class, in 1704, he selected twelve pupils distinguished for 'piety, knowledge, and aptness for teaching,' and constituted them his *seminarium præceptorum*, the fame of which soon spread throughout Germany. Hundreds were attracted by the superior organisation and improved methods of Francke, and among his pupils were Johann Julius Hecker, who subsequently established similar institutions at Stettin in Pommern in 1735, and in Berlin in 1748. To promote the system, Friedrich the Great, the patron of Hecker, declared by royal ordinance that all vacancies in the crown-land schools should be filled by teachers trained in the Berlin seminary. Besides this he granted an annual stipend to twelve of the graduates, a number afterwards increased to sixty. Before long the seminaries at Rekahn, in Brandenburg, had eclipsed all others, and the system began to spread beyond the boundaries of Prussia. It found its way into Hanover in 1757, into Austria in 1767, into Switzerland in 1805, into France in 1808, into Holland in 1816, and into England in 1842. Since then it has been adopted in every country of Europe, with the solitary exception of Turkey, and teachers' training schools are now to be found not only throughout the British colonies, but in India, Japan, and the states of S. America. In 1875 there were 115 in Italy, 101 in Prussia, 73 in other German states, 104 in British India, 86 in France, 64 in Austria, 63 in Hungary, 45 in Russia, 41 in England, 33 in Belgium, 32 in Switzerland, 31 in Spain, 13 in British colonies, 10 in Sweden, 8 in Rumania, 7 in Norway, 6 each in Scotland and Portugal, 5 each in Holland and Denmark, 3 in Finland, and 1 each in Ireland, Luxemburg, Servia, and Greece. The first public normal school in the United States was opened at Lexington in 1839, and in 1876 there were no fewer than 137, with 1046 instructors and 29,095 students. Large as this number may appear, it is being rapidly increased, for at present the graduates do not amount to more than one-tenth of the number of teachers required for the common schools. In the United States the regular training schools are supplemented by 'Teachers' Institutes, which differ from the former mainly in being temporary although official bodies formed of those already holding appointments.

The Prussian system, which forms the basis of that of all countries, is characterised by organic completeness, by the combination of ample liberty with adequate restriction, and the satisfactory solution of 'the religious difficulty.' The course of instruction is for three years, and the training is of an essentially practical character, a notable feature being the prominence given to music. The subjects of study added to those in which a certain proficiency is ascertained by entrance examinations, are Latin, French, often English, botany, and pedagogy. In addition to the intellectual training, the students are instructed in certain industrial duties relating to the management of a household, garden, &c. The system in England reflects the main peculiarities of that of Prussia. A Committee of Education had stirred public interest by its report before the Liberal Government, and in 1839 appointed an educational Committee of the Privy Council, to which the House of Commons voted £30,000 for distribution. Mr. James Kay, afterwards Sir James Kay Shuttleworth, the secretary of this committee, after the committee itself had failed in an attempt to found a training college, succeeded in establishing such an institution without the aid of government. The various religious bodies followed his example, and within six years England had 15 training schools. This gave the denominational character to the system which characterises it to the present day. All training schools are under control of one or other of the Churches, and only one body—the Independents—took no distinct action except in founding and maintaining Homerton College. In 1846 the Committee of Council made the further step of establishing an elaborate system of inspection, with grants, and by 1859 these grants had increased to £836,920. In 1868 Mr. Lowe introduced the economical principle of payment by results, based on the new plan of individual examination, as opposed to the inspection of schools as a whole. He thought that Government should pay for the teaching of the three R's alone, and devised standards in these which scholars might be expected to rise to in one year. He assigned a money value for each of the subjects, and allowed to managers of schools a sum according to the number of passes gained by pupils in examinations. The essential merits of this plan have insured its vitality, in spite of its enmity to the higher branches, and its tendency to reduce instruction to a process of 'cramming.' The Code, the document containing regulations respecting the standards and passes, undergoes yearly changes. Since the passing of Mr. Forster's Act of 1870, the yearly grant appropriated in Parliament, and administered by the Education Department, is intended to maintain primary schools and training colleges for teachers. The recognised classes of teachers are (1) certificated teachers, (2) pupil-teachers, and (3) assistant teachers. Certificates are obtained on examination, which is open to students who have resided for at least one year in training colleges, and to candidates, over 21 years of age, who have either completed satisfactorily an engagement as pupil-teacher and obtained a favourable report from an inspector, or served as assistants for at least six months under certificated teachers. The certificates are of three classes, and are only granted after the candidates have served in probation as teachers. No certificate above the second class is originally issued; the third or lowest includes special certificates for teachers of infant classes. Good service alone entitles any teacher to a certificate of the first class. Those of the second class remain in force for ten years. A training college includes both a 'college for boarding, lodging, and instructing candidates' for elementary schools, and a 'practising school in which they may learn the exercise of their profession.' Annual grants are made to training

colleges, as to elementary schools; each college is entitled to £100 for every master and £70 for every mistress who, after two years' training, completes the prescribed period of probation and becomes qualified for a teacher's certificate, or who has completed a like period of good service as an elementary teacher in the army, royal navy, poor-law schools, or any certified industrial schools or reformatories. In 1878 the accommodation provided by the colleges in England under inspection was sufficient for 3157 students, and 3080 (1701 females) were in residence. They can turn out 1500 teachers yearly, and this would supply the average deficiency (6 per cent.) in a staff of 25,000 teachers. Besides these, a large number of candidates enter the profession by other channels recognised by the Code. The extent to which training colleges have operated in furnishing the existing staff is shown by the fact that of 11,135 masters and 13,706 mistresses examined in 1876, as many as 6746 and 6735 respectively had been trained for two years, 1195 and 1147 for one year, and 343 and 274 for less than one year. In 1877 the average salary in England of certificated masters was £115, and of mistresses £69; but in addition to salaries free residences were held by 5213 out of 10,694 masters, and by 4656 out of 13,103 mistresses. In Scotland the Code of 1873 introduced a provision allowing the combination of the training-college course with university attendance, and in 1878-79 no fewer than 130 normal school students were attending university classes, chiefly in the departments of mathematics, Greek, and English literature. In 1877 among those examined for certificates were 14 university graduates (22 in 1874). It was intimated in 1877 that a gradual reduction would be made from year to year in the number of students educated at public expense at Scotch training colleges, and that fewer Queen's scholarships would be awarded yearly. The Queen's scholars, it was resolved, would be limited to 700 (380 females) in the Church of Scotland and Free Church colleges, but My Lords have since 'agreed not to enforce for 1879 the full reduction of Queen's scholars which they propose eventually to make.' They allow 215 new scholars to be admitted from 1st January 1879 in place of the number (175) originally proposed. At Christmas 1878 the class-list of students in Scotch training colleges examined for certificates numbered 1043. Of these 190 (101 females) in Edinburgh, 190 (95 females) in Glasgow, and 78 (all females) in Aberdeen, attended the training colleges of the Church of Scotland, while 192 (106 females) in Edinburgh, 209 (128 females) in Glasgow, and 74 (all females) in Aberdeen, attended those of the Free Church. An Episcopal college in Edinburgh had an attendance in 1879 of 59 (all females). See Turner's *Educational Legislation* (Lond. 1876).

Tra'jan's Col'umn, a celebrated monument of Rome, and the *chef-d'œuvre* of Apollodorus, erected by the Roman senate and people in honour of the emperor in 114 A.D. It still stands in the Forum of Trajan, and is constructed entirely of marble. The shaft is 87 feet high, and whole, including pedestal and statue, 147 feet. Around the column runs a spiral band 3 feet wide and 660 feet long, covered with well-preserved reliefs from Trajan's war with the Dacians, comprising, besides animals, &c., 2500 human figures, the size of which, 2 feet below, gradually increases upwards. Beneath the column Trajan was interred, and on it was placed his statue, for which that of St. Peter has been substituted. A staircase in the interior of 184 steps leads to an open platform at the top. The reliefs, which are reproduced in casts preserved in the Lateran, are invaluable for the light they throw on Roman costume.

Tra'jan's Wall, a line of fortifications in the south of the Dobrudscha, extends from the Danube, at Czernavoda, to a point on the Black Sea, near Kustendji, a distance of 37 miles. It consists of a double (in some parts a triple) line of earth ramparts about ten feet high, bounded on its N. side by a natural fosse formed by a marshy valley, which was long erroneously regarded as an old course of the Danube. The wall was an important defence in the Russo-Turkish war of 1854, and the invaders were twice repelled in attempts to pass it—at Kostelli (April 10), and Czernavoda (April 20-22). A railway was constructed along the route in 1860, and the great cost has been the main obstacle to a project of carrying a ship canal across the valley for the purpose of avoiding the long and difficult passage by the Sulina (q. v.) mouth of the Danube. Another wall of the same name, constructed by a Roman legion 105-155 A.D., stretches from the Pruth E. to the Black Sea, and is included in the territory 'restored' to Russia by the treaty of Berlin, 13th July 1878. —**T.'s Pass** (Turk. *Demir Kapi*, 'iron-gate'), across the Ichtiman Mountains, between Sofia and Philippopolis, was occupied in the recent war by the Russians, 11th January 1878.

Traja'nus, Marcus Ulpius, was born at Italica, near Seville, September 18, 52 A.D. He was trained to arms, and in his early youth served with distinction in Germany and in the East. He became consul in 91, and was in 97, with the general approbation, adopted by Nerva as his successor. In January 98, on the death of Nerva, he became emperor, and signalised his accession by remitting the corn-duties and abolishing the odious function of the *delatores*. In 101 he set out against the Dacians, and during the next two years subdued their country and obliged their king Decabalus to accept his terms. In 103 he entered Rome in triumph, and in the following year began the second Dacian war, which ended in 106 with the death of Decabalus and the reduction of his country to the form of a Roman province. During this war T. built a permanent bridge across the Danube. On his return to Rome he enjoyed a triumph and exhibited games for 123 days. He now devoted himself to the construction of great public works, made a road across the Pontine Marshes with *mansiones* at intervals, great military roads throughout the whole empire, with magnificent bridges over the rivers, and an artificial harbour at Centum Cellæ (Civita Vecchia). His chief works in Rome were a theatre and several public libraries, among these, the *Ulpia Bibliotheca*, and the great Forum Trajanum, in the centre of which stood Trajan's Column (q. v.). In 114 he set out against the Armenians and Parthians, wintered at Antioch, and in the following summer invaded Parthia, overran the whole country in two campaigns, and took Ctesiphon the capital. In 116 he descended the Tigris and sailed down the Persian Gulf. Meanwhile a revolt of the Parthians had been subdued by his generals, and T. on his return placed Parthamaspes on the throne. In 117 he began to sink from a combination of dropsy and paralysis, and accordingly set out for Rome, but died on the way at Selinus in Cilicia (afterwards called *Trajanopolis*), August 11, 117, after a glorious reign of 19½ years. T. was the second in the series of good emperors which included Nerva, Hadrian, and the Antonines. Though the bent of his mind was for war and great works, he thoroughly reformed the finance and purified public justice, while under him the provincials enjoyed a mild government and the Christians a respite from severer persecution. See Francke, *Zur Geschichte T.* (Quedlinb. 1840), Dierauer, *Beitrage zu einer Kritischen Geschichte T.* (Leip. 1868), and C. D. La Berge, *Essai sur le Règne de T.* (Par. 1877).

Trajec'tory, in dynamics, is the path described by a body, such as a planet, comet, projectile, &c., under the action of given forces. In geometry the name is given to a curve or surface which cuts all the curves or surfaces of a given system at a constant angle. When this angle is a right angle, the T. is then called an orthogonal T. Loxodromic lines may be cited as examples of a T. upon the surface of a sphere, cutting all great circles at the same angle. The logarithmic spiral is the T. of a plane pencil of rays through its pole, and a circle is the orthogonal T. of the same.

Tralee' (Ir. Gael. *Traigh-Li*, 'the strand of the Lee'), a town at the mouth of the Lee, on the W. coast of Ireland, 22 miles N.W. of Killarney by rail. It is well built, and the four principal streets, which are wide, meet in a small square. Two Roman Catholic, an Episcopalian, and several other churches, a town-hall, court-house, barracks, and infirmary are the chief public buildings. There are monuments to the Kerry men who fell in the Crimea and in India. A considerable provision trade is carried on. In 1877, 588 ships of 78,697 tons entered and cleared this port; the customs revenue, which is gradually decreasing, was £3167; the imports were valued at £165,379. Pop. (1871) 9506, of whom 8563 were Roman Catholics, and 746 Protestant Episcopalians.

Tramm'el-Net (Low Lat. *tramallum* or *tramela*, from *tres maculæ*, 'three meshes'), a fishing net, of which there are two kinds. That used in the S. of Ireland resembles the ordinary drift net in depending perpendicularly in the water and entrapping the fishes by the gills in the meshes, but it is prevented drifting with the tide by means of anchors and weights; hence in other

parts of the United Kingdom it is known as a *Set-Net*. The real T.-N. is found on the S.W. coast of England and in the Channel Islands. It consists of three long nets set parallel and fastened together at the edges, the centre one being much larger than the other two, so that there is much slack netting. A fish may pass easily through the large meshes of either of the 'wallings,' but in doing so it encounters the inner net, which is fine-meshed, and drives a portion of the slack netting through the opposite large mesh, thus forming a bag or pocket in which it becomes 'trammeled.'

Tram'way. A T. consists of a narrow, smooth, continuous track, prepared to form a course in which the wheels of any carriage or waggon, having the gauge of the two parallel lines, may run more smoothly and with less friction than on the surface of an ordinary road. The term T. is corrupted from Outram, the name of an engineer who, towards the end of last century, constructed such wheel-tracks in connection with colliery and other mine-roads in the N. of England. The system is, however, of much earlier origin, continuous wooden tracks having been used in connection with Newcastle collieries more than two centuries ago. About 1765 a development of the system occurred when cross-sleepers were laid under the longitudinal planks, which were then raised above the level of the roadway, and, to keep the waggons on the track, the wheels had fixed to them a flange or projecting rim. In 1767, during a period of commercial depression, the Coalbrookdale Company laid down a track of cast-iron instead of wood, with the intention of taking it up and selling it at a subsequent period, and this really formed the first iron railway, the prototype of all railways as well as tramways. At a later date rail-plates were cast with a flanged edge, so that the guiding flange was transferred from the wheel to the rail. Thereafter many different modifications of both rails and wheels were devised till the forms now generally adopted were evolved. In 1809 a T. or horse railway was projected between Cheltenham and Gloucester, and subsequently an Act of Parliament was obtained, and a line opened for passenger traffic in 1821. The system, however, of street tramways, as now established, with grooved rails and flanged wheels, was first proposed by a French engineer, M. Loubat, in America, and was there carried out in many of the principal towns. In several Continental towns also the T. system was introduced before it began to attract much attention in the United Kingdom. In 1857 or 1858 an eccentric American—George Francis Train—made proposals for laying T. lines in various metropolitan thoroughfares and in several provincial towns. In 1861 an experimental line was laid down by Train in London, but it became the subject of bitter controversy and lawsuits, and after a short existence had to be removed. A similar fate would have befallen Train's lines at Birkenhead and Hanley, had the objectionable rail used by him not been withdrawn and a better form substituted. In 1868 an Act of Parliament was passed sanctioning the laying down of T. lines in Liverpool; in 1869, after severe contests, three local Acts were passed for London, and since that period the formation of tramways has been sanctioned and carried into effect in all the very large towns in the United Kingdom. On 30th June 1878 there were throughout Great Britain 268 miles of T. and 346 authorised; 9222 horses employed, and 1124 cars. The gross receipts of the financial year were £1,145,465; the working expenses, £868,315; and the capital expended, £4,207,350.
The use of some form of mechanical power on T. lines in place of horses is a subject which has attracted a great amount of attention, and several kinds of road steamer have been suggested and introduced. The heat generated, the noise, and the appearance of the exhausted steam of the engines, have, however, been the most serious obstacle to the use of steam-power on roadways used for ordinary carriage traffic. To overcome these difficulties Mr. Scott Moncrieff, of Glasgow, proposed the use of highly-compressed air, and he devised an apparatus by which a loaded car could travel several miles with one charge of compressed air. A 'fireless locomotive' invented by Emile Lamm has met considerable success in the United States. In this machine the boiler is charged from a stationary boiler with water superheated to 380° F., whereby an initial steam pressure of 170 lbs. is obtained. Messrs. Merryweather & Sons, of London, have attained very considerable success in the adaptation of engine power to the haulage of T. cars, and upwards of sixty engines made by that firm are in use in various Continental cities. Steam-power has for several years been in use on the Vale of Clyde tramways at Govan, a suburb of Glasgow, the engine being enclosed within a small separate car which draws the passenger car, thus presenting the appearance of two cars, a smaller and larger running together. The engines now in use were constructed by Hughes of London, and the noise is so slight, and the smoke and fire are so little seen, that no complaints of frightening horses have arisen in connection with the working of the lines by this form of mechanical power. Mekarski's T.-Car, in which heated compressed air is the motive power, has been successfully run on the tramways of Paris. See Dowson's *Construction and Working of Tramways* (Lond. 1875).

Trance, or Mor'bid Sleep, is a condition closely allied to sleep, but differs from it as regards duration and profound insensibility to external impressions. *Death T.* is, according to Dr. Mayo, a positive status; a period of repose, the duration of which is sometimes definite and predetermined, although unknown. 'The basis of death-T. is suspension of the action of the heart, of breathing, and of voluntary motion; generally, likewise, of feeling and intelligence; and the vegetative changes in the body are suspended. With these phenomena is joined loss of external warmth, so that the usual evidence of life is gone.' Regarding this hypothesis, Dr. Taylor says:—'It is obvious that the writer makes no distinction between life and death. All the ordinary phenomena of life may have ceased, and yet, if from any circumstance the decomposition of the body has been retarded, it may be contended that the body is not dead, but simply in a death-T. The entire absence of the ordinary signs of active life is sufficient, according to this physiologist, to prove the absence of life—a proposition which may be granted in reference to a *few hours* of time, but it would be unreasonable to adopt this method of inquiry, and judge of death by the presence of *one* sign only, instead of taking these signs in their totality and ordinary sequence.' There are no well-authenticated cases on record in which T. has simulated death for any length of time. See CATALEPSY and HYSTERIA.

Tra'ni, a town of S. Italy, province of Bari, on the Adriatic, 95 miles W.N.W. of Brindisi by rail. It is an archbishop's see, has a cathedral, built about 1100, with a Romanesque portal and bronze doors of 1175, the fine church Sta. Maria Immaculata, several convents, a castle, a theatre, an orphanage, a high school, a technical school, and a priests' college. T. has important fisheries, and considerable trade in oil, corn, almonds, figs, and excellent wine ('Moscado di T.'). The harbour is to some extent sanded up. T. is the ancient *Turenum* of the Peucetii, and was in the Middle Ages an important seaport. It was taken and burnt by the French in 1779. (Pop. (1874) 24,388.

Tranquebar', a small town in the district of Tanjore, Madras Presidency, British India, on the Coromandel coast, at the mouth of one of the arms of the Cauvery river. It was originally a Danish settlement, founded as early as 1617, but was ceded to the British in 1845 for a money consideration. In its castle of Dansborg, the European architecture of all its houses, and the cleanness of its streets, it recalls its founders. The manufactures and trade are inconsiderable, but T. is celebrated as the first home of missionary effort in India. In 1706, under the patronage of Frederik IV. of Denmark, the missionary Ziegenbalg arrived, who translated the New Testament into Tamul. In after years came the respected Schwartz; and numerous churches still flourish under Lutheran and English episcopal direction.

Transbaika'lia, a province of the Russian Empire, E. Siberia, lying S. and E. of Lake Baikal (q. v.). Area 240,774 sq. miles; pop. (1873) 447,568, among whom more than a third are heathen Mongols, Tungusians, &c. T. is a diversified mountain-land, richly wooded, with fine pasturage. Its metallic wealth is great, consisting of silver, lead, gold, copper, tin, coal, and asphalt. The centre of the mining industry is Nertchinsk (q. v.), the chief town is Tschita (q. v.).

Transcauca'sia, the part of Asiatic Russia lying S. of the Caucasus, between the Black Sea and Caspian. See CAUCASUS.

Transcen'dent, or Transcenden'tal (Lat. *transcendo*, 'I go beyond'), is a philosophical term meaning that which lies beyond sense or experience. The Schoolmen called that which could not be embraced under the ten categories of Aristotle, T. In Kant (q. v.) the philosophy of T. elements of knowledge are the *à priori* factors not contained or derivable from, but regula-

tive of, experience. In ordinary language T. is often used (not quite correctly) to mean something apart from ordinary subjects. Thus the poetry of Shelley is called T., and by this is probably meant that it deals with elevated and unusual moods of thought and feeling. See A. J. Balfour's *Transcendentalism* in '*Mind*' (October 1878).

Trans'epts, in cruciform churches, are the wings or cross-aisles projecting N. and S. from the eastern end of the nave.

Transforma'tion. See METAMORPHOSIS OF ANIMALS.

Transfu'sion of Blood is a surgical operation by which blood is conveyed directly from the body of one person to that of another. The earliest case of T. of B. on record is that of Pope Innocent VIII., who was unsuccessfully operated on in April 1492. Various experiments were afterwards made by Wren and Lower in the T. of B. from one animal to another, and by Denys of Montpellier in injecting the blood of calves into human subjects; but the experiments were not attended with any great success, so that the operation fell into desuetude. This was in great measure due to the fact that the experimenters supposed that, by the T. of B. of healthy subjects or of the inferior animals, into the veins of the diseased and enfeebled, disease would be expelled and life prolonged. It was not till about the year 1824, when Dr. Blundell published his work on *Physiological and Pathological Researches*, that the T. of B. was regarded as a legitimate operation in obstetric surgery; and at the present day the operation is chiefly restricted to cases of profuse hæmorrhage in connection with labour, though it is sometimes practised in cases of sudden and profuse hæmorrhage from other causes. Cases of intermittent fever have been treated by transfusion in foreign countries, but without any very encouraging results. The operation is best performed by taking blood, instantly before injection, from the arm of a healthy person; but Dr. Brown-Sequard has shown that the blood of various animals can be used indiscriminately, provided only certain precautions be taken; and Professor Panum has made the important discovery that defibrinated blood is in every respect as well suited for the operation as pure blood. Lately, Mr. Wagstaffe has used milk, and milk mixed with an equal quantity of defibrinated blood, for injecting into the veins. Instead of blood, the following saline solution has been recommended by Dr. Little for injection:—Chloride of sodium, 60 grs.; chloride of potassium, 6 grs.; phosphate of soda, 3 grs.; carbonate of soda, 20 grs.; distilled water, 20 oz., the solution being injected at blood-heat. See *Obstetric Society's Transactions*, vol. vi. May 4, 1874; *Medical Times*, September 5, 1874.

Tran'sit In'strument, an instrument mounted so as to observe the meridian passage of a star. It was invented by Rœmer, the famous Danish astronomer, about the year 1690, and is described in the *Miscellanea Berolinensia*, tome iii. 1700. Halley erected one at Greenwich Observatory in 1721, but it was little used till 1742, when Bradley began his regular meridional observations. In 1861 Troughton set up a larger and improved instrument, which was superseded in 1850 by the large transit circle now in use. The T. I. consists essentially of a telescope movable only in the meridian plane. Though primarily intended merely to *time* the passage of a star, the obvious addition of a graduated circle makes it available for altitude measurements. The great essential of such an instrument is that it moves accurately in the plane of the meridian. It must therefore be fixed at right angles to a horizontal axis, which rests in a stable frame so as to lie due E. and W. It is impossible in practice to have these conditions accurately fulfilled, and the errors of adjustment must be known and allowed for before the readings of the instrument can be trusted. The three principal errors to which a T. I. is subject are (1) the *error of collimation*, due to the optical axis of the telescope not being at right angles to the axis of rotation; (2) the *error of inclination*, due to the axis not being level; and (3) the *error of azimuth*, due to the axis not being E. and W., or to the optical axis not being in the meridian plane. See Herschel's *Astronomy*, and Loomis' *Practical Astronomy*.

Transi'tion Rocks, a term now disused, which was applied by the older geologists to those formations which seemed intermediate between the so-called 'Primitive rocks,' such as granite and gneiss, and the ordinary stratified rocks, which were called 'Secondary' or 'derived.' The T. R., which were also classed under the vague name of grauwacké, now enter into the Cambrian and Silurian formations. Geologists still, however, apply the term in a general sense when describing any beds which, lying between two formations, partake of the characters of both, and indicate a gradual passage from one to another: *e.g.*, the Llandovery Rocks, between the Lower and Upper Silurians.

Transmigra'tion, or the supposed passing of the soul into another body at death, is a belief which, as an instinctive conception, has been almost universal among barbarous and half-civilised tribes, from the ancient Gauls to the Tasmanians of the present day, and from Mexico to Tibet. As a speculative theory it has had a place in the philosophy of all time. It is one of the cardinal doctrines of the Vedas, the oldest literature of India; and it held a prominent place in the ancient religions both of Persia and Egypt. Some of the Essenes and Pharisees among the Jews held the doctrine, which, in their case, was probably of Persian origin. Not a few of the older Greek philosophers—*e.g.*, Pythagoras, Empedocles, and Plato—held it; and through the Neo-Platonism of Alexandria it found its way into the Christian church, and was accepted by some of the Patrists, *e.g.*, Origen, as well as by the heretical Gnostics and Manichæans. Though condemned by the Council of Chalcedon (551), it kept a certain hold on Christian theology, and re-appeared among the Schoolmen. It has been praised by English divines and poets, and among modern philosophers has been advocated by Hume, Lessing, Herder, Fourier, Leroux, &c.; and it remains the creed of all the millions of Buddhists.

There are three possible forms in which the doctrine may be held—1. That it extends to all forms of life, so that the highest may change places with the lowest, and *vice versâ*. Certain obvious facts of experience might give rise to this belief: (1) the superficial resemblances in feature, disposition, and character between men and the lower animals might suggest that the bodies of animals were inhabited by human souls, and those of men by animal souls; (2) physical, mental, and moral features re-appearing in families after an interval of generations might induce the supposition that an ancestor had returned to life; (3) thoughts and sensations which cannot be traced back to any source in past experience might seem to warrant the inference of the soul's pre-existence; as it is expressed in Indian philosophy, 'joy, fear, and grief arise to him that is born, through relation to his memory of things previously experienced.' 2. A second theory of T. is that which would limit it to the animal world, denying it to the human. 3. The third form is that the T. may apply both to the human and to the animal world, but that the souls of men never descend below the human level, while those of animals never ascend into the human form. The philosophical grounds on which T. has been maintained are threefold:—(1) The first, which was forcibly stated by Plato, is our knowledge of ideas which are not the product of experience. If these be latent in the soul at birth, they must have come from a previous state of existence. (2) Some philosophers have found in T. the key to the unequal adjustment of happiness and misery in the present life; without it, they say, it is impossible to 'vindicate the ways of God to man.' (3) Applying the doctrine of the conservation of energy to the sphere of spiritual life, it is argued that the number of souls in the universe must be fixed and constant. If the amount of spiritual existence is not increased, the pre-existence of all souls is as certain as their immortality.

Tran'som, in architecture, the horizontal mullion or cross-bar of a window, rarely found in the Early English, oftener in the Decorated, most frequently of all in the Perpendicular style.

Tran'som, in artillery, a strong bar formed of timber connecting the two corresponding parts of a gun-carriage. The length of the T. regulates the width of the vehicle. Wooden siege-carriages are connected by three transoms. Transoms in ships are the beams bolted across the stern-post.

Transplanta'tion of Tissues. Modern surgery has, within recent years, been very fertile in numerous discoveries, and especially as regards the T. of T. Professor Nussbaum of Munich, in 1875, described a new operation for the loss of bone which he denominates *transplantation of bone*. It consists of cutting off from the rest of the bone a portion of its external shell, covered by the periosteum, and leaving this shell of bone attached to the remainder by means of the periosteum covering its terminal extremity. This semi-attached bone is displaced into the gap in the same way as a flap of skin is twisted in a plastic

operation, and fixed in the indurated soft tissues of which the gap is formed. The operation was first performed in a case of non-union of the ulna, the result of loss of bone from a gunshot fracture. Attempts have also been made to *transplant* periosteum which may form the nidus of bone. The transplantation of skin may be effected by displacement, or by torsion. The first mode is effected by dissecting up a piece of skin, of the required size and shape, a portion of it being left attached. The loose portion is then shifted into the part where it is intended to lie. In the method by torsion, the position of the flap of the skin is changed, and the neck of skin, forming the attachment, is made as slender as is consistent with the maintenance of vitality. In both cases the edges of the transplanted skin are brought into close contact by means of stitches, with the cut edges of the skin where union is desired. Transplantation of skin can be effected from one part of the body to another, as from the arm to the nose, or from the thigh to the hand. *Transplantation of skin*, by grafting, was invented by M. Reverdin of Geneva in 1869, and was introduced into British surgery by Mr. Pollock in 1870. This operation is peculiarly adapted to cases where large granulating surfaces are exposed, as in cases of extensive burns. It is essential that the granulations should be perfectly healthy, and that all irritation in the sore should have ceased. The operation may be performed with a pair of fine forceps and sharp curved scissors. A small portion of skin, hardly larger than a pin's head, is snipped off with the scissors. The whole thickness of the skin should not be cut through, but only a small portion of it, so as to make sure of removing the *rete mucosum*, as the growth of the graft seems to depend on the cells of the *rete Malpighii*. The grafts are placed firmly on the granulations, about an inch apart, and are covered with oiled silk, moistened with oil to prevent its sticking when removed, and the whole is fixed with strapping and covered with cotton wool. The dressing should be renewed in three or four days. The grafts first change into little, round, vascular-looking buds; and in a short time the new cuticle is seen extending in all directions from the bud. That the new skin is due to the graft is evident from the fact that a graft from a negro placed on a European produces a dark-coloured skin; and a graft from a European transplanted on a negro produces a white portion of skin. Very recently T. of T. has been introduced into dental surgery. See Dr. Page in *British Medical Journal*, March 27, 1871.

Transplant'ing is taking up a plant with its roots and replanting it again in such a manner that it shall continue to grow. As applied to horticulture, it consists in the removal of small plants from one bed to another, for the purpose of increasing their growth, and does not call for any special notice here. The following remarks are therefore limited to T. in its application to arboriculture, or the removal of large trees, whether for ornament, shelter, or for screening unsightly objects. The art was not unknown to the ancients, as is shown by the writings of Pliny, Seneca, &c., but was carried out on no fixed principles. It first came into practice in England about 1550. T. on a gigantic scale was undertaken by Louis XIV. of France, who transferred from Versailles most of the large trees in the Bois de Boulogne. The machines in use at this early period were unwieldy and complicated, being constructed to carry the trees in an upright position; and the trees, both head and roots, were much mutilated. Early in the present century the system of selection and preparation in T. large trees was reduced to scientific principles by Sir H. Stewart of Allanton, N.B. Successful T. is dependent upon several conditions, of which the most important are:—1. Selection of proper trees and their adaptation to the soil. As a rule, none should be chosen for a poorer soil than that from which removed, but much may be done by a liberal use of composts, by drainage, trenching, &c. 2. A careful preparation of both trees and soil, by cutting a trench around the tree, filling with good composts, and leaving for two to four years for proper root-growth to take place. 3. The time and method of removal. For deciduous trees late in autumn is the best time; much care is necessary to loosen the soil among the roots. After the tap-root is severed the T.-machine ('janker') is brought alongside, the tree is lashed firmly to the pole, and, by means of the leverage so obtained, is brought into a horizontal position, after which horses are attached, guide-ropes applied, and with roots carefully packed up and protected, removal is made to the new site. 4. The manner of fixing and disposition of the roots. The soil upon which which the tree is lowered should be thoroughly consolidated, the roots should be feathered out to avoid crossings and interlacings, and finely pulverised soil must be interspersed in small quantities at a time. 5. After-treatment. The surface, under which the roots spread, should be well covered to promote consolidation and to prevent evaporation. Ramming during the first spring is serviceable, and liberal waterings in the summer months.

Trans'port, the conveyance of troops and of everything necessary for their support and armament by land or sea. Water is the cheapest and most convenient means of T. The insular position of this country and its military relations with every part of the world has necessitated the use of a large number of T.-ships. In the admirably constructed and commodious vessels sailing between Portsmouth and Bombay 270 tons are required for every 100 men. Navigable rivers in a foreign country are easy for T., but they are seldom available for the conveyance of troops to the front of positions. Waggons and military carts are attached to all armies to carry stores from the principal magazines to those at different stages on the line of march, and carts carrying a certain number of days' rations are attached to each division. There is also a regimental T. for the conveyance of light baggage and camp equipments. A two-horse waggon can draw 800 lbs., a four-horse waggon 1800 lbs., and a six-horse waggon 3300 lbs. Wheel T. on a good level road is about five times more servicable than pack T., but in a very hilly and rough country the latter must be resorted to. All the procurable carrying animals of the district are then pressed into the T. service. A mule will carry upwards of 200 lbs. in a level country and 100 in a mountainous country, a bullock about the same amount, a camel twice as much, and an elephant 15 to 20 cwt. in a level country, and 10 to 12 cwt. in a mountainous country. Railways are invaluable where they can be used on a large scale, as in the Franco-Prussian War, where the Germans had direct railway communication from their own country to Paris. Two trains of about thirty-four carriages each, propelled by single engines at the rate of from 20 to 25 miles an hour, will convey an infantry battalion of 1100 men with their equipments, or a battery of horse-artillery or field-battery with men, horses, and equipments. One similar train will convey a squadron of cavalry. The T. of a division of the English army would require twenty-six such trains, and of a full army corps 144 trains. The T. department of the English army is a subdivision of the control department. In time of peace it is employed in the conveyance of commissariat supplies, and on public works, arsenals, &c.

Transporta'tion, Legal. See PENAL SERVITUDE and TICKET OF LEAVE.

Transpose' (in music). To T. is to alter the key of a musical composition either into a higher or lower scale. It is a useful exercise for students, as a new key often requires a new position of chords, and calls ingenuity in part-writing into requisition. *Transposing instruments* are those which produce a different pitch of notes from those written. A *transposing piano* is a pianoforte with a movable key-board by which the pitch of the instrument can be altered.

Transubstantia'tion (Lat. 'a change of substance') was a name first made use of to denote the change of the Eucharistic elements of bread and wine into the body of Christ in the beginning of the 12th c. The earliest Schoolmen had maintained the doctrine in a way, employing similar phrases, *e.g.*, *transitio*; and as the doctrine of the Mass (q. v.) was gradually developed, it was finally distinctly stated (first by Anselm of Canterbury) that the whole Christ was present both in the bread and the wine. The doctrine was now solemnly confirmed by being inserted in the Gratiani Decretum (q. v.), and by a General Council (Lateran IV., 1215) under Innocent III.; although a manifold controversy arose on the point. At the Reformation, the Reformers, while differing widely in their opinions regarding the doctrine of the Lord's Supper (q. v.), one and all opposed the doctrine of T., as well as the notion of the sacrifice of the mass. The doctrine of T. is to be distinguished from that of the Real Presence (q. v.), inasmuch as the latter may, and is generally understood to mean that the body of Christ co-exists in and along with the elements, whereas according to the doctrine of T. the body of Christ takes the place of the elements, only the appearance of the latter remaining.

Transvaal' ('across the Vaal'), a British territory in S.E. Africa, bounded on the N. by the river Limpopo (q. v.), on the E. by the Lobombo range and Zululand, on the S. by Natal and the Orange River Free State, and on the W. by the Kalihari Desert and Bechuanaland. Its greatest length from N. to S. is 425 miles, its greatest breadth from E. to W. 375 miles, and its area 120,000 sq. miles. The country is a plateau sloping inland from the mountains forming its eastern frontier, whose height is 7000 feet, and whose seaward face is abrupt and precipitous. The centre of the T. is traversed by several ranges running at right angles to the main chain, the chief being the Magaliesberg, which forms the watershed of the Vaal and Limpopo systems, and has an average height of 5000 feet, with peaks rising to 9000 feet. Physically the T. consists of three great divisions, known as the High, Terrace, and Bush country respectively. The first has an area of about 40,000 sq. miles, and is an elevated, well-watered region, well adapted for grazing and agriculture. The second lies along the mountain slopes, and has an area of 20,000 sq. miles. It is well wooded, and its pastures feed large herds of cattle. The Bush country has an area of 60,000 sq. miles, lies lower than the other two divisions, and in its northern part has a tropical climate. Its grass, though excellent fodder in winter, is too rank for domesticated animals in summer. Under irrigation, fruit-trees, the sugar-cane, coffee, indigo, and tobacco thrive, and wheat also, as a winter crop. The large game, once common everywhere, have now retired to the remoter parts of this region, where lions, rhinoceroses, &c., are still to be met with, and crocodiles infest the rivers. Taken as a whole, the T. is a fertile country, well adapted to the cultivation of most tropical and semi-tropical crops. Its wheat, in particular, is of the finest quality, and has already earned for the T. the title of 'the granary of South Africa.' Sheep, cattle, and horses thrive, except in districts infested by the dreaded Tsetse Fly (q. v.); but as the winter is also the dry season, it is necessary to move the flocks and herds when the pastures become bare. The remedy for this lies in a system of irrigation. N. of the parallel of 25° S. lat., fever is common, but elsewhere, and especially in the more elevated districts, the country is remarkably healthy. The mineral wealth of the T. is very great. Rich gold-fields, both quartz and alluvial, are worked at Leydenburg, Marabastad, and Blaaubank, and silver, copper, cobalt, and plumbago are found in many places. Iron and lead are very plentiful, and coal of the best quality abounds almost everywhere. The great lack of the country is a port, as it is 100 miles from the sea at the nearest point, and its trade is therefore carried on through Natal or Delagoa Bay. A railway from the latter to the Leydenberg gold-fields has long been projected, but through Portuguese supineness is not yet commenced. News, however, was brought by the Lisbon mail (December 1878) that the Portuguese government had at last agreed to join the English government in constructing a railway between Lorenzo Marquesas on Delagoa Bay and the T., the cost of which was estimated at £350,000. The capital of the T. is Pretoria (q. v.), but it is rivalled, if not surpassed, by Potchefstroom, 90 miles to the S.W., in a lovely district. The white pop. of the T. was estimated in 1877 at fully 40,000, and the native pop. at 250,000, but the latter is a purely conjectural figure. The natives are inferior to their neighbours the Zulus in physique, but are more inclined to industrial pursuits.

The earliest settlers in the T. were the Boers (q. v.), who crossed over from Natal and established a republic in 1840, their leaders being Maritz, Potgieter, and Pretorius. The republic was acknowledged by Britain at the Sound River Convention, signed on 17th January 1852, and existed till 12th April 1877, when the T. was annexed to Cape Colony, on the ground that the native policy of the republic threatened to bring about a general Kaffir rising in S. Africa. The annexation was protested against by the Volksraad or Parliament of the T., and in spite of it a native rebellion broke out in January 1878, and is still (Feb. 1879) unquelled. See Silver & Co., *Handbook to the T.* (Lond. 1877); Noble, *South Africa, Past and Present* (Lond. 1877); Trollope, *South Africa* (Lond. 1877); Gilmore, *The Great Thirst Land* (Lond. 1878); Harriet Roche, *On Trek in the T.* (Lond. 1878); Aylward, *The T. of To-day* (Lond. 1878), and General Sir A. T. Cunynghame, *My Command in S. Africa* (Lond. 1879).

Transylva'nia (Ger. *Siebenbürgen*), a grand-duchy and crown-land of the Austro-Hungarian monarchy, surrounded by Hungary, the Bukovina, Moldavia, and Wallachia. Area, 21,216 sq. miles; pop. (1870) 2,115,024. T. is so called from its position beyond the wooded Carpathians; its interior is a table-land intersected by spurs from the Carpathian ranges, rising in the S. (in Negoi) to 8060 feet, in the N. to 7000, in the W. to 5840, and in the E. to 5700, while its average elevation is about 1500 feet above the sea, its lowest point being where the river Maros enters Hungary (566 feet). The chief rivers, all belonging to the Danube system, are the Aluta, falling into the Danube, Samos, and Maros (tributaries of the Theiss), and the Bistritz, an affluent of the Sereth. Of the whole area, 23 per cent. is arable, 25 per cent. meadowland, and 38 per cent. forest. The best wine is produced in the valleys of the Samos, Kotel, and Maros. In 1877 the yield per sq. kilogr. of beet-root was 122·55 kilogr.; of tobacco, 85·76 kilogr.; and of flax and hemp, 490·86 kilogr. The mining industries of T. are directed by the 'Captainship of Zalatna,' and included (1875) the production of 34,614 metric tons of iron ores, and 16,774 of pig-iron (produced by 15 blast-furnaces). Other mineral products are gold, silver, quicksilver, copper, coal, and salt. Tanning and the manufacture of linens, woollens, and glass, are also important. Originally a part of Dacia, T. was conquered by King Stephan I. in 1004, and united to Hungary. About this period the country was invaded by Germans, probably from the Rhine districts, who named it *Siebenbürgen*, after the seven fortified towns built by them. Ever since this little Saxon colony has retained, unchanged, its peculiar laws and language, there we find cities with names like Kronstadt, Hermanstadt, Klausenburg, Elizabethstadt, and Muhlenbach, in a district surrounded by places with Slavonic, Magyar, and Wallachian names. From 1526 to 1699 T. was an independent kingdom under the Zapolya princes. Completely subdued by Leopold I. in 1687, and united to Hungary in 1713, it became a grand-duchy in 1765. In 1848, T. was the theatre of a bloody struggle between Bem and the Russians, and was for a time united to Hungary. Since 1849 it has been an independent crown-land. See Professor D. T. Ansted, *A Short Trip to Hungary and T.* (Lond. 1862); and C. Boner, *T., its Products and its People* (Lond. 1865).

Trap, a name rather loosely and vaguely applied to a great number of rocks of volcanic origin, which can be easily distinguished on the one hand from the granites, and on the other from the aqueous or fossiliferous rocks. T. is liable to almost infinite variation, just as in recent lava-streams hardly any two are to be found of identical composition, and the more important subdivisions of the class—*e.g.*, amygdaloid, basalt, greenstone, and porphyry—have been already described. The name T. (from Swedish *trappa*, 'a stair') was proposed by the mineralogist Bergmann, owing to the terraced or step-like arrangement which may be traced in many of these igneous rocks.

Tra'pa, a small genus of *Onagraceæ* occurring in central and S. Europe, tropical Africa, and eastwards through Asia. All are floating herbs. Of the European *T. natans*—water caltrops, or water-chestnut—the farinaceous seeds are collected in Italy, &c., and eaten raw, or ground into flour and made into bread. The plant is also cultivated for this purpose. *T. bispinosa*, the Singhari nut of India, forms in Cashmere and other districts an important staple article of food. *T. bicornis*, the Leng or Ling of China, is regularly cultivated in lakes and ponds by the Chinese, and is brought extensively to market.

Trapa'ni, a coast town in the W. of Sicily, 23 miles W. of Palermo. The *Cattedrale S. Lorenzo*, a town-house, a lyceum, and a library are the chief public buildings. The town is well built, strongly fortified, and has a good natural harbour. The manufacture of sea-salt is the chief industry, but corn, wine, fish, and coral are also exported. In 1874, 174 vessels (52 British) of 55,327 tons entered and cleared. The imports and exports fluctuate greatly; the former in 1874 rose from £3537 in 1873 to £18,180; while the latter fell from £55,238 to £16,126. Pop. (1876) 36,045. T. is the ancient *Drepanum* or *Drepana* (Gr. *drepanē*, 'a sickle,' so called from the shape of the adjoining promontory). It was fortified by Hamilcar in 260 B.C., and here in 249 Adherbal defeated the Roman fleet. Near it is Mount Eryx, now *Monte S. Giuliano*. Important discoveries of human and other bones in caves were made in 1869.

Trape'zium is a Quadrilateral (q. v.), no two of whose sides are parallel. When only two are parallel, the figure is called a *trapezoid*, and must be plane.

Trapézoid, the smallest bone of the second row of the wrist bones, of which there are eight in man. It is wedge-shaped, the broad end or base lying next the arm. Above, the T. articulates with the *scaphoid* bone of the wrist, and below, with the palm-bone of the first finger or that next the thumb. It also articulates with the *os magnum* and the *trapezium*, a bone of the lower row of the carpus or wrist, to which the thumb is specially attached.

Trapp'ist Order, or the Reformed Bernardines of La Trappe, was in a sense a new order of monks founded (1664) by Armand de Rancé (q. v.), but was properly a reformed community of Cistercians (q. v.). Abbot of the Cistercian monastery of La Trappe, the discipline of which had become extremely lax, Rancé was arrested, about the year 1662, in a thoughtless and luxurious life, by some circumstances of which various romantic accounts have been given, and, setting the example himself, he introduced into the monastery a system of excessively austere discipline. The time of the monks, who had to live entirely on bread, vegetables, and fruit, was divided between manual labour, the canonical exercises, and private devotions. Their conversation was confined to the greeting *Memento mori;* their worship was kept up day and night; and if a monastery contained as many as twenty-four monks they were divided into three classes, which interchanged duties continually. For a time the order was confined to France. Being dispersed at the Revolution, they found a home in Switzerland, Italy, Spain, America, and England. After the restoration of the Bourbons they obtained possession of their old house of La Trappe, which still remains the head monastery of the order. About 1840 a branch of the T. O., with a modified organisation, and under the name of 'Trappist Preachers,' was established at Pierre-qui-Bire, near Avallon. See Gaillardin, *Trappistes* (Par. 1844), and Pfannensch, *Geschichte der Trappisten* (Paderb. 1873).

Trasime'nus, Lacus. See PERUGIA, LAKE OF.

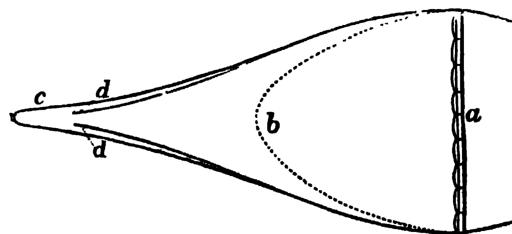
Trass, an unstratified tufaceous alluvium, probably of Pliocene age, found forming great deposits in the district of the Lower Eifel. It is probably of volcanic origin, and is compared by Sir C. Lyell to the 'Moya' of the Andes. For the most part it is composed of pumice, and contains also lumps of lava, pieces of half-burnt rock, and vegetable remains. It is used to a considerable extent as a hydraulic cement, like the Italian pozzuoli.

Travancore', a native state in India, occupying the S.W. corner of the peninsula, bounded N. by Cochin, and separated by the Ghauts from the Madras districts of Madura and Tinnevelly. Area, 6730 sq. miles: pop. (1875) 2,311,379. The mountains inland rise to the height of 6000 feet; they produce valuable timber, and on their slopes cardamoms and coffee are cultivated. Wild beasts are numerous, of which the most remarkable is the black species of panther. From the mountains, rivers dash on the narrow strip of plain, and terminate in back-waters and lagoons, among which rice is grown, and the cocoa nut and the areca nut abound. Another staple product is pepper, and nutmegs and cloves are also grown. T. enjoys the reputation of being the best-governed state in India. The administration was for many years in the hands of the late Dewan, Sir Madhava Rao. In ten years one million stg. was spent on public works, and there is no debt. Education and sanitary requirements are as well cared for as in a British province. The revenue is over £500,000, of which half comes from land, and £100,000 each from salt and tobacco. Of the expenditure, £100,000 is for public works; £81,000 British tribute; £57,000 temples; £56,000 administration; and £54,000 palace. Both Christians and Mohammedans sit on the judicial bench, as well as Hindus, for there is a considerable Mussulman and Christian native pop.—T. town, the former capital, is now deserted; the present seat of government is Trevandrum, where there is a first-rate college and hospital. The present dynasty, who are Kshattriyas, was established about A.D. 825. According to the ancient Malabar custom, descent is traced only in the female line. The British had a factory on this coast as early as 1684; and the first treaty dates from 1788, when the British bound themselves to protect T. against Tippoo Sultan, in consideration of a subsidy to be paid in cash or pepper. The present rajah, whose family name is Tirupadatu Swarupam, is a G.C.S.I. He is a highly educated man, understanding English perfectly, and being an excellent Sanskrit scholar. The 'First Prince' has similar intellectual tastes.

Trav'ellers, Laws Affecting. See under CARRIERS, *Carriers, Wharfingers, and Warehousemen, Laws Respecting.*

Trav'eller's Tree constitutes the monotypic genus *Ravenala* of the natural order *Musaceæ*—differing from *Musa* in habit, by having a tall, simple, woody trunk and distichous leaves. It bears the name of *R. Madagascariensis*, or is sometimes still called by its older title of *Uranea speciosa*. This noble and unique plant is a native of Madagascar, and is now subspontaneous in Mauritius. The leaves surmounting the palm-like trunk diverge on opposite sides from the summit, 'somewhat in the same way as the ribs of a fan from its centre,' each consisting of a footstalk 6 to 8 feet long, and an oblong, bright-green, shining, undivided blade of 4 to 6 feet. The flowers are crowded in the axils of large spathes along the terminal flower-stalks, and the seeds surrounded by a pulpy blue arillus are in a woody 3-celled capsule. In the cup-like base of the leaf-stalks a considerable quantity of water is contained, which can be tapped by piercing from below; and this supply, being availed of by thirsty travellers, has originated the name of T. T. The leaf-blades are used for thatching, the seeds are edible, and the blue aril furnishes an essential oil.

Tra'vemünde, a seaport of N. Germany, in the free territory of Lübeck, at the mouth of the Trave on the Baltic, 9 miles N.E. of Lübeck, of which it is an outport. It is a sea-bathing place, visited by about 1000 persons annually. Till the deepening of the Trave in 1852, T. was the sole port of Lübeck. Pop. (1875) 1719.



Tra'verse, a word of varying significance in military language. In fortification, traverses are portions of parapet formed of mounds of earth about 18 feet thick, thrown across ramparts to protect the guns and strengthen the defence. In gunnery, to T. is to direct a gun either to the right or left of its position, an operation accomplished by means of handspikes or wheel-screws. *Traversing platforms* are used for the efficient working of guns of 9 tons and upwards. The guns are mounted on truck-carriages or rollers in batteries. The gear of a platform of this kind is of two main portions, one for traversing, and the other for running the carriage in. It is worked by winch-handles, arranged so that the two portions may be detached when necessary. There are common, dwarf, and casemate traversing platforms.

Trav'ertin, the Italian name of a white calcareous stone, deposited from solution in the water of mineral springs, and occurring in great abundance in volcanic regions.

Trav'esty (Ital. *travestire*, 'to disguise'), a kind of burlesque in which the original characters are preserved, the situations parodied. Such are Comic Histories, Scarron's *Virgile Travesti* (1648), and Monbron's *Henriade Travestie* (1758).

Travnik', or **Traunik'**, a strongly fortified town of Bosnia, on the Lasva river, an affluent of the Bosna, in a swampy district at the foot of Vlaschiz-Planina, 45 miles W.N.W. of Serajevo. It has a citadel, a castle of the Middle Ages, 20 mosques, a Servian church, a synagogue, &c., and makes sword-blades. The Catholics dwell apart in Matosch or Solatz. Pop. 12,000. Near T. are the salt springs of Lepenicza. T. was the capital of Bosnia till 1850.

Traw'ling (a form of *trailing*), a mode of fishing which consists of dragging a kind of bag-net, called a trawl, along the

Beam Trawl.

bottom of the sea, and which is largely prosecuted during the winter season on the English, Irish, and Dutch coasts, and in the North Sea, our supplies of 'ground fish,' such as turbot,

plaice, brill, soles, skate, and other flat fishes, besides haddock, whiting, and kindred fishes of the cod family, being principally thus obtained. The trawl is a long triangular-shaped net, closed at the narrow extremity by a line and kept open at the wide end in various ways. The 'beam-trawl' (see fig.) is in most general use. It owes its name to the fact that a wooden beam (a), from 36 to 50 feet in length, is employed to keep the mouth of the net extended, the 'square' end of the 'back,' or upper side of the net, being fastened to it. The beam is fixed at its ends to iron frames, called 'trawl-heads' or 'head-irons,' which raise it 3 feet from the ground. The lower portion or 'belly' of the net has its edge (*b*) deeply curved in order that a considerable portion of the 'back' may have passed over the fishes resting in the mud before they are disturbed by the 'ground-rope' attached to the edge of the 'belly,' and so lessen their chance of escape. The narrow extremity of the net is called the 'cod' (*c*), and into it all the fishes pass and for the most part remain; some, however, particularly the soles, in seeking a way of escape, enter the 'pockets' (*dd*), which are formed by lacing together a portion of the 'back' and 'belly,' and get jammed therein. The 'cod' being, from the weight of the captured fish, subject to much wear, is covered on the under side with overlapping pieces of old nets. Smacks and luggers are the vessels usually employed in T. From the end of a 6-inch rope, or 'trawl-warp,' 150 fathoms long, depending over the stern of the vessel, two 'bridle-ropes' branch off, one to each 'head-iron,' where it is shackled; and by this gearing the trawl is towed for five or six hours in the same direction as the tide. When the tide has turned, the trawl is heaved up and emptied of its contents by undoing the 'cod-line.' On the S. and W. coasts of Ireland a 'pole' or 'hammer-trawl' is in use. The mouth of its bag has two long tapering wings of netting, which are weighted at the lower edge and corked at the upper. The extremity of each wing is fastened to a ⊥-shaped contrivance of iron called a 'hammer,' and the trawl is towed along by two ropes connecting the hammers with poles rigged out on each side of the trawling vessel. Smooth shallow water is essential to the good working of this trawl. The principal deep-sea T. stations in the United Kingdom are Plymouth, Brixham, Dover, Ramsgate. Lowestoft, Yarmouth, Grimsby, Hull, Scarborough, Fleetwood, Liverpool, Carnarvon, Tenby, Dublin, Waterford, Dingle, and Galway. On the W. coast of Scotland the sean or sweep-net, employed for catching herrings, is erroneously termed a 'herring-trawl.' Complaints of the destruction of spawn by beam-T., and the generally 'mangled' condition of the captured fish, were disposed of as groundless in the *Report* (issued in 1866) of the Royal Sea Fisheries Commissioners.

Traz-os Mon'tes ('beyond the mountains'), a province in the N.E. of Portugal, bounded N. and E. by Galicia and Leon (Spain), W. by Entre Douro e Minho, and S. by the Douro, which separates it from Beira. Area, 3999 sq. miles; pop. (1875) 374,837. Besides forming the southern frontier, the Douro follows great part of the W. boundary, and the province is watered by its affluents, the Sabor, Tua, and Tamega. T. is the loftiest part of Portugal; in the N. it is entered by the mountains of Leon (culminating in Serra de Monte Zinho, 9080 feet), and throughout has a wild, highland character. The district of Alto-Douro is noted for its port wine, while the uplands yield sumach and the valleys wheat, rye, hemp, flax, maize, oranges, almonds, &c. Silk is cultivated to some extent, and there are iron mines and mineral wells. The chief exports are mules, wool, silk, and wine. The capital is Bragança.

Trea'cle. See SUGAR.

Tread'mill, an invention for enforcing prison discipline, consists of a cylindrical wheel furnished with twenty-four equidistant radial steps. The prisoners, supported by a handrail before them, tread from step to step, imparting to the wheel a continuous rotatory motion, which may be usefully applied for grinding corn or turning other material. The T. was introduced into the prisons of Great Britain by Sir William Cubitt of Ipswich, and was first erected at Brixton gaol in 1817. The Chinese use a similar apparatus to raise water for irrigation.

Trea'son (Fr. *trahison*, Old Fr. *traïson* from *traïr*; Lat. *tradere*, 'to betray'). According to the common law of England, the nature of high T. is vague, and any act tending to lessen the dignity of the crown was formerly held to be within its scope. But an end was put to constructive T. by 25 Edw. III. c. 2, which defines the crime. Statutes of the reigns of Geo. III. and Geo. IV. confirm and expand the statute of Edward III. By these Acts the definitions of T. are as follows:—To intend any bodily harm to the king or his heirs—the intention being only capable of proof by an *overt* act, as by providing a weapon, or by sending a letter to incite another to join the enterprise; to have sexual intercourse with the queen-consort, or with the king's eldest daughter, unmarried; by *overt* act, to levy war against the king in his realm, or to try to force the repeal of a law by violence; by *overt* act, to adhere to the king's enemies within the realm, or to assist them; to counterfeit the great seal, privy seal, privy signet, or royal sign-manual; to slay a judge, under specified circumstances. By 1 Anne, c. 17, to endeavour to subvert the Act of Settlement (q. v.) is T. By 3 and 4 Vict. c. 52, to marry or be concerned in promoting the marriage of any child of her present Majesty, being under eighteen years of age, should the crown have descended to him or her, without the written consent of the regent and of both Houses of Parliament, is capital T.; and to assist any one having committed this crime to escape is a treasonable offence. The Act of 1870 abolishes forfeitures on account of T., but conviction of the crime disqualifies the criminal for certain civil and ecclesiastical offices.

Treas'urer, Lord High, the third great officer of the crown, was formerly a person of high rank, appointed by letters patent, in whom the custody of the royal treasury, the appointment of all officers employed in collecting the revenue of the crown, and the government of the upper court of the exchequer, were vested. A lord in virtue of his office, he sat among the barons. The first L. H. T. of England was Odo, Earl of Kent, who filled the office in the reign of the Conqueror. John de St. John was the first L. H. T. of Ireland (1217), and Sir Walter Ogilvie the first L. H. T. of Scotland (1420). The L. H. T. of England became L. H. T. of Great Britain on the Union between England and Scotland, and L. H. T. of the United Kingdom in 1816 when the revenues of Great Britain and Ireland were united. The Duke of Shrewsbury (in 1714) was the last person who executed the trust as an individual. Since the Hanoverian accession its functions have been entrusted to a commission, which now consists of five 'lords commissioners for executing the office of L. H. T.' See TREASURY.

Treas'urer of the Household is the second officer of the Lord Steward's department. The Treasurer of the Chamber was formerly an important officer and member of the Privy Council, who discharged the bills of the king's tradesmen. This office was abolished in 1782.

Treas'ure-Trove is treasure found *in* the earth, of which the owner is unknown. It belongs to the Crown, but the finder will be paid the intrinsic value. To appropriate T.-T. is an offence punishable by fine and imprisonment.

Treas'ury, The, one of the principal departments of the executive of the United Kingdom, having the entire control of the Treasury and disbursement of the public revenue. The Board of collection, whose offices are in Whitehall, consists of five lords-commissioners, viz., the First Lord of the T., the Chancellor of the Exchequer, and three junior lords. The First Lord of the T. is the official title of the head of the Administration, or the Prime Minister, and may be a member of either House of Parliament. His salary is £5000. He has an extended ecclesiastical, legal, and civil patronage, the appointment of all the principal officers of state, and the regulation of the various departments under the Crown. As chief of the executive his duties are so multiform that he exercises little practical control of the T., unless in the rare event of his holding in addition the office of Chancellor of the Exchequer. The Chancellor of the Exchequer is to all intents and purposes head of the T. He must be a member of the House of Commons, and has also a salary of £5000. The preparation of the budget devolves upon him, and he is the parliamentary mouthpiece of the Government in all matters relating to finance. In addition to the junior lords of the T. there are two joint-secretaries to the department, who are connected with the Administration and are members of the House of Commons, and also a permanent official secretary. One of the joint-secretaries to the T. is usually also the chief 'whipper-in' of the Government, who has the non-official but important duty of looking

after the interests of his party in the House of Commons, by securing the attendance of as many members as possible at important divisions. The T. has the appointment of all officers engaged in the collection of the public revenue; the army, navy, and civil service supplies are issued under the authority of the T.; and all exceptional cases and disputes in the matter of revenue are referred to its decision. The custody of the public revenue is vested in the Exchequer, and all sums withdrawn from the Exchequer must be vouched for by a Treasury warrant. Several important departments are subordinate to the T., such as the Boards of Customs and Inland Revenue, the Post-Office, the Woods and Forests, &c.

Trebb'ia (anc. usually *Trebia*), a river of N. Italy, rises in the Apennines near Genoa, and flows N. for 51 miles, falling into the Po near Piacenza. Here Hannibal defeated the Roman consul Sempronius in the spring of 217 B.C., when the river was swollen by melting snows. It was also the scene of a fierce struggle between the French under Macdonald and an Austro-Russian force under Suvarof on the 17th, 18th, 19th, and 20th of June 1799, in which the former were defeated.

Trebin'je, a town (formerly capital) of Herzegovina, on the Trebinschitza, 17 miles inland from Ragusa. It is the seat of a Catholic bishop, and has a garrisoned castle. Pop. 10,000 (or according to Roskiewicz, 3000). During the war of the Austro-Hungarian occupation, Suleiman Pasha was shut up at T. with 1500 men, and an equal number of Bosnian troops joined the insurgents here, 20th September 1878.

Treb'izond (Turk. *Tirabzon*; Gr. *Trapezus*, 'the table,' so called from the square shape of the town), the principal Turkish port on the Black Sea, on the N.E. coast of Asia Minor, and the second commercial city of the empire, 110 miles N.W. of Erzerum, with which the only communication is by badly-kept roads. It is finely situated on the steep slope of the Kolat Dagh (800 ft. high) facing the sea, and is partly surrounded by walls, and further defended by a Genoese citadel on an adjoining hill, and by forts at the mouth of the harbour. The gorge-like course of a mountain stream traverses T., and is crossed by several bridges. The coast is high and crested with pine-woods, and from the sea the irregularly-built town, with its minarets and gardens, has a striking appearance. There are 18 mosques, 15 Christian churches, and many elegant baths and spacious bazaars. The industries, chiefly weaving and dyeing, are unimportant; but the products of the surrounding country, which form part of the exports of T., comprise considerable quantities of boxwood (612,383 cwts. exported in 1875), loupes or walnut-tree knobs, valued in France for veneers, beans (12,626 cwts.), wheat and Indian corn (22,376 quarters), fruit and provisions (18,329 cwts.), nuts and walnuts (11,169 cwts.), skins (15,953 bales, value £63,812), wool (£17,900), tiftick and fillick (£72,480), tobacco (12,458 bales, £49,832). T. is an emporium for the Persian trade, but has suffered greatly from the opening of the railway from Tiflis to Poti (q. v.). It is a terminus for caravans from Erzerum, Armenia, Kurdistan, Tabriz, &., and has regular communication by steam-line with Constantinople, the Danube, and French ports. The harbour is only an open roadstead, and during the autumn equinoxes vessels have to shelter either at Batoum or at Platina, 6 miles W. In 1875 there entered and cleared the port 315 steamers (101 Turkish, 103 Russian, 53 French, 53 Austrian, 5 British) of 231,836 tons, and 5242 sailing-vessels of 31,620 tons. The total value of exports was £886,742, and of imports £1,426,011 (£838,298 from Britain). In 1877 the imports from Britain had fallen to £155,012 for local distribution, and £476,190 for transit to Persia. The exports from Persia amounted to £594,073, and the imports for Persia to £388,790. Besides the opening of the Poti Railway, the want of good roads in the interior, the neglect of the larger crown-forests, and the imposition of heavy custom dues, have checked T.'s prosperity. Mr. Biliotti, the English consul, says (1879) that if there were 'a carriageable road and means of transport between T. and the Persian frontier, many years would elapse before, if ever, Batoum attracted all the trade;' but should the Persian road be neglected, 'before many years elapse T. will have no more importance than Ooniah or Ordoo.' Pop. 50,000. T., founded by a colony from Sinope, 756 B.C., was a great trading town in Xenophon's time, and continued to flourish as an emporium for the Indian trade under the Roman empire. Its period of greatest prosperity as capital of the Comnenian empire of T. began in 1204 and lasted till 1461, when David, last of the Comnenes (q. v.), was captured by Mohammed II. Since then T. has belonged to the Porte. See Fallmerayer's *Geschichte des Kaiserthums von Trapezunt* (Mun. 1827), and *Fragmente aus dem Orient* (Stuttg. 2d ed. 1877).

Treb'le, the highest voice in women or boys, also called *Soprano* (q. v.). The treble or G clef, 𝄞 where G is placed on the second line of the stave, is the higher clef for keyed instruments and voices.

Tred'egar, a mining town of Monmouthshire, England, 12 miles W.S.W. of Abergavenny by rail, has grown up during the present century, and contains a town-hall, market-house, &c. The collieries and iron-works of the T. Iron Company employed 8131 hands in 1871, the total pop. of the town being 12,389.

Tree may be defined as a perennial plant with a woody trunk exceeding a man's height, and scarcely branching from the base. Excepting the palms and a few other endogens, all trees belong to the two great botanical divisions, exogens and gymnosperms, the latter including all cone-bearing trees and the former all other trees of the temperate regions of the world. The mode in which the branches come off from the trunk, and the angle at which the branchlets proceed therefrom, together with the comparative length of the upper and under branches, give rise to great differences in the contour of trees—a difference added to by the diversity of foliage. Although dense forests of immense area exist in temperate and cool zones of the N. hemisphere, the number of species is very limited compared with the luxuriant forests of the tropics. Thus Western Europe possesses scarcely 50 indigenous species of forest trees, while in the *Forest Flora* of British Burmah 2000 species have lately been described, and in most tropical countries the proportion of woody flora to the herbaceous is from 1½ to 3 of former to 1 of the latter. At the Philadelphia Exhibition upwards of 400 kinds of wood were shown as the native produce of the varied territory of the United States. The age of trees has a very wide range, from some of the palms which die at about forty years after once flowering, to the yew, baobab, sequoia, and others, which are supposed to attain 3000 years; and in like manner the height attained varies from 20–30 feet to 420 feet. The value of trees as regulating the climate and productive capacity of a country has already been adverted to. See ARBORICULTURE, TIMBER TREES, &c.

Tree'-Crab (*Birgus*), the name applied to certain crabs which are ranked among the 'land-crabs.' *B. latro* is a familiar species. It breaks open the shell of the cocoa-nut and of other fruits by repeated blows of its great claws. The T.-C. can live for long periods out of water, but deposits its eggs in the sea, to which it makes periodical journeys.

Tree Ferns are those species of *Filices* forming the giants of the fern race in which the stem (*caudex*) becomes arborescent. This is the case in the genus *Dicksonia* and in the tribe *Cyatheæ* (of Smith), in which the tree-like stems reach a height of 50 feet or even more, and are surmounted by a crown consisting of immense fronds sometimes measuring 20 feet in length. As the plants grow and the fronds fall, scars of an oblong-rhomboid form are often left arranged spirally around the stem, and such marks are also found on fossil fern-stems of the coal measures. The T. F. are widely distributed within or near the tropics, the southernmost limit being Tasmania, New Zealand, and Juan Fernandez. They occur at a considerable altitude in the Himalaya. A handsome species, named *Cyathea medullaris*, contains in its trunk a mucilaginous pulp comparable to sago, which is used extensively for food in Polynesia and New Zealand. The stems of *Alsophila excelsa* serve for building purposes, and 'last an incredibly long time.'

Tree-Frog (*Hyla*), a genus of frogs forming the type of a distinct family (*Hyladæ*), of the order *Anoura* (q. v.). It occurs on the continent of Europe, and also in the New World. The *H. arborea* is the common T. F., called *Rainette* in France. The body is of a bright green colour, and so nearly approaches the foliage of trees in hue, that the creature can be detected amid the foliage only with difficulty. The characteristics of the T. F. are found in the presence of suckers in the toes. In other

respects it resembles ordinary frogs. The *Hyla versicolor*, the common T. F. of America, is abundant in the N. of the United States. Another species (*H. viridis*) is found in the W. and S. The T. F. is exceptionally active, and pursues its insect-prey with avidity. The croak is loud but not unmusical, and on the approach of wet weather the animal becomes specially demonstrative.

Tree Kangaroo (*Dendrolagus*) is so named from its arboreal habits. It belongs to the kangaroo family (*Macropodidæ*), but differs from the true kangaroo in having its fore-legs nearly as long as the hinder members. The tail is not used to support the body as with the ordinary kangaroo, and the claws are very long and curved. The T. K. occurs in New Guinea.

Tref'oil (Lat. *trifolium*, 'three-leafed'), a frequent charge in heraldry, is usually represented *slipped*, or provided with a stalk. In architecture it is an ornament of three cusps in a circle.

Tref'oil, a name given more particularly to the clovers, but applied often by English farmers to *Medicago lupulina*. Birds'-foot T. is *lotus;* marsh T. the buck bean or *Menyanthes*. A number of other plants are also locally called T.

Treitsch'ke, Heinrich Gotthard von, an able German publicist and historical writer, born at Dresden, September 15, 1834, studied at Bonn, Leipzig, Tübingen, and Heidelberg, became *privat-docent* in history at Leipzig in 1858, and 1863 professor at Freiburg, resigned his chair in 1866 in consequence of the attitude of Baden in the German crisis, and went to Berlin, where he undertook the management of the *Preussischen Jahrbücher*, to which he had contributed since 1858. In the autumn of 1866 he was called as a professor to Kiel, and next year accepted a chair in Heidelberg, which he vacated for another at Berlin in 1874. Since 1871 he has been a member of the Reichstag. His chief works are: *Die Gesellschaftswissenschaft* (Leip. 1859); *Historische und Politische Aufsätze* (3 vols. 4th ed. Leip. 1871); *Zehn Jahre Deutscher Kämpfe*, 1865-74 (Berl. 1874); and *Der Socialismus und seine Gonner* (Berl. 1875).

Tremat'oda, an order of *Platyelmia* (q. v.) or Flat-bodied *Scolecida* (q. v.) allied to the *Tænada* or Tape Worms, and represented by the various kinds of Flukes (*Fasciola*). The characters of the T. are the flattened and leaf-like character of the body and the presence of one or more ventrally-placed suckers, the most anterior of which is perforated by the mouth. There is no anus or vent, but a branched digestive system is developed. No true perivisceral space or body-cavity occurs, and the sexes are as a rule united. There are no cilia on the integument of the adult. The T. undergo a further metamorphosis during development. T. in their native state inhabit the alimentary canal and its appendages as a rule; but they may occur under the skin—as in the case of the *Fasciola hepatica* or Common Liver Fluke, whose normal situation is the liver and bile-ducts of the sheep, in which animal it produces the disease known as 'Rot' (q. v.); this fluke also occurs in man's liver, or occasionally beneath the skin. The common fluke presents a good example of the group. The body is flattened and of oval shape. There are two suckers, the anterior perforated by the mouth, the lower or *acetabulum* being imperforate. The digestive system consists of a set of branched tree-like tubes ending cæcally, while the nervous system consists of two ganglia situated in the head and sending filaments backwards. The embryos pass through a metamorphosis, and find a first lodgment within the body of the fresh-water snail, where they become tailed organisms or *Cercariæ;* these, being swallowed by the sheep, pass to the liver, and there become the adult flukes. The genus *Distoma* or *Fasciola* includes the typical forms of T., and *D. lanceolatum* is another species in which the alimentary canal is not branched. Another genus of T. is *Bilharzia hæmatobia*, found in the blood-vessels of man in Egypt, S. Africa, Mauritius, and other regions. The male attains the length of ½ an inch, and the female 1 inch; the sexes being, contrary to the general rule amongst the T., distinct in this genus.

Tremell'a, a genus of *Fungi*, the type of the order *Tremellini*, distinguished by a tremulous gelatinous texture. The species vary much in form and in colour. They generally occur on the dead branches of trees and shrubs.

Trem'olite (from *Val Tremola*, in Switzerland), a variety of the mineral hornblende, of a grey or greenish colour, and usually occurring in long, prismatic, translucent crystals. The specific gravity of T. is 2·93, and it fuses with difficulty before the blow-pipe into a colourless glass. It occurs in dolomite, crystalline limestone, and other of the older rocks.

Trem'olo, Tremolan'do, in music, trembling caused by the rapid repetition or alternation of notes. Also a vibration of the voice in singing suitable for the production of certain effects, but often too much and too indiscriminately used by vocalists.

Trenail (Old Eng. 'wooden nail'), a long wooden peg about 1 to 1¾ inch in diameter, used in shipbuilding for securing planking to the timber, &c. Trenails are commonly made of teak or oak.

Trench. See SIEGE.

Trench, Richard Chevenix, born at Dublin 9th September 1807, from Harrow proceeded to Trinity College, Cambridge, where he graduated B.A. (1829). Taking orders, he became curate at Hadleigh (1833-35), incumbent of Curdridge (1835-40), curate to Archdeacon Wilberforce at Alverstoke (1840-44), and rector of Itchenstoke (1844-45); then, having held the Hulsean lectureship (1845-46), the chair of philosophy at King's College, London (1846-58), and the deanery of Westminster (1856-63), he was consecrated Archbishop of Dublin, 1st January 1864. Between 1835 and 1846 T. published six volumes of Wordsworthian poetry, reissued in *Poems, collected and arranged anew* (1865); but it is as a writer on philological and theological subjects that he is most widely popular. His numerous works include *Notes on the Parables* (1841; 13th ed. 1847), *Notes on the Miracles* (1846; 10th ed. 1874), *On the Study of Words* (1851; 16th ed. 1876), *Proverbs and their Lessons* (1853; 6th ed. 1869), *Synonyms of the New Testament* (1854; 8th ed. 1876), *English Past and Present* (1855; 10th ed. 1877), *Studies in the Gospels* (1867), *Plutarch, his Life, his Lives, and his Morals* (1874), and *Lectures on Mediæval Church History* (1878).

Trenck, Franz, Freiherr von der, was born January 1, 1711, at Reggio, in Calabria, where his father was an Austrian general. At the age of seventeen his excesses obliged him to fly from Austria, and accordingly he entered the Russian service, but was in a short time for his insubordination cashiered and sentenced to six months' hard labour at Kiev. He next returned to his estates in Croatia, and raised a force of 1000 Pandours, which he placed at the service of Maria Theresa in 1740. He was distinguished during the War of Succession by his reckless courage, but the atrocious cruelty and rapine of his followers have made his name a byword in modern warfare. In 1745 he was found guilty by a court-martial of having communications with the enemy, and sentenced to imprisonment for life at Brunn, where he died, October 14, 1749. See his untrustworthy Autobiography (Leip. 1748; 2 vols. Vienna 1807); and Hübner, *Franz von der T.* (3 vols. Stuttg. 1788-89).—**Friedrich, Freiherr von der T.**, cousin of the preceding, was born at Konigsberg, February 16, 1726. At the age of fourteen he entered the Prussian army, and at eighteen was a favourite aide-de-camp of Friedrich the Great. In June 1745, on account of a detected correspondence with his cousin, the Pandour captain, and his extravagant passion for the Princess Amalie, he was suddenly flung into prison at Glatz. On the 24th December 1746 he succeeded, after many vain attempts, in escaping, on which he fled first to Vienna and afterwards to Russia. In 1748 he entered Prussia in order to visit his family, but was arrested at Danzig and committed to a rigorous confinement at Magdeburg. He was liberated in December 1763, and had his property restored in 1787. He commenced business at Aix-la-Chapelle as a wine merchant, but being unsuccessful, in 1790 went to Paris, where he attached himself to the Jacobin party. He was guillotined as a Prussian spy, July 25, 1794. His Autobiography, *Merkwürdige Lebensgeschichte* (4 vols. Berl. 1786; Fr. trans. 1789) for a time made this 'loud, blustering, extensively fabulous blockhead,' the hero of the fickle Parisians, and in our own times his life has been made the subject of a historical romance (3 vols. Celle 1860). See Poiteau, *Aventures du Baron du T.* (Par. 1853).

Trent, a river of England, which rises in the hills of N. Staffordshire, in a pond near Kinpersley, 10 miles N. of Burslem. It flows S.E. through Staffordshire till it receives the Tame, when it turns N.E., and enters the Humber near the mouth of the Ouse. Its chief tributaries are the Sow, Blythe, Dove, and

Derwent, on the left; and the Tame, Soar, Devon, and Idle on the right. Its length is 148 miles. It is navigable up to Burton for barges, and is subject to a bore or 'eagre.' The basin of the T. and Humber is the largest in England, its area being 9100 sq. miles.

Trent (Ger. *Trient*, Ital. *Trento*, Lat. *Tridentum*), an old town of Austria in the Tyrol, on the left bank of the Adige, 51½ miles N.N.E. of Verona by rail. It has two suburbs, San Martino and Santa Croce, and in its environs villages rise beautifully above one another on the mountain slopes. Of the town, which is quite Italian in its character, the finest squares are the Piazza d'Armi and the Piazza del Duomo, the latter adorned with a fountain, and containing the courts of justice. Among the 15 churches the finest are the Cathedral, a Romanesque basilica, with two domes, founded in 1048, begun in its present form in 1212, and completed in the 15th c.; Santa Maria Maggiore, where the celebrated Council of T. (q. v.) sat from 1545-63, containing an admirable organ, and adorned with portraits of the members of the council; and the Church dell' Annunziata, with a high cupola resting on four pillars. Other buildings are the town-hall, the Palace of Justice, the theatre, and the Palazzo Buon Consiglio, formerly the residence of the prince-bishops, now a barrack. The town has two monasteries, a theological institute, an upper gymnasium, and a public library and museum. The industries are silk-spinning and weaving, dyeing, iron-founding, and the manufacture of cloth, pottery, and cards. In the vicinity are great marble quarries. Pop. (1869) 17,073. T. was a Roman *colonia*, became in the 4th c. the seat of a bishop, and in 574 of a Lombard duke. In 1027 Konrad II. granted to its bishops princely rank and the fief of the town. The bishopric was secularised in 1803, and added to the Austrian crown-lands. See Barbacovi, *Memoire Storiche della Città e del Territorio di T.* (Trent 1808); Lupi, *Topografia della Città di T.* (Trent, 2 vols. 1831); Perini, *T. e suoi Contorni* (Trent 1859).

Trent, Council of (*Concilium Tridentinum*), the eighteenth in order and the first in importance of the 'Œcumenical' councils recognised by the Roman Catholic Church, was called forth by the Reformation in the 16th c., and demanded by both parties in the contest, for the reform of church discipline and the settlement of the points of controversy. After being repeatedly postponed by the intrigues of the Papal court and the rivalries of Karl V. and François I., it was convened at Trent as an exclusively Roman council by Pope Paul III., December 13, 1545. In March 1547 it was transferred to Bologna, but was reopened at Trent, by Pope Julius III., May 1, 1551. It was broken up, January 18, 1562, in consequence of the victorious advance of the Elector Moritz, but was recalled by Pope Pius IV., January 18, 1562, and reached its close, at its twenty-fifth session, December 4, 1563. Its decrees and canons, which were confirmed by a bull of Pius IV., January 26, 1564, are drawn up with much clearness and precision, though the doctrines of the Protestants are often exaggerated or falsified. They were immediately acknowledged in Spain, Portugal, Italy, Poland, and Catholic Germany, and, in their doctrinal part, in France. The principal articles of faith decreed, with anathemas, were the canon of Scripture, with the Church as sole interpreter, progressive justification, the seven sacraments, transubstantiation, purgatory, the invocation, veneration, celibacy of the clergy, and auricular confession. The *Decreta* and *Canones* were first published by Paul Manutius (Rome 1564), and have been frequently edited; the best edition is that by Schulte and Richter (Leip. 1853), the latest that by Pess (Regensb. 1877). The history of the Council of T. has been written by the liberal Sarpi (q. v.) and the Ultramontane Pallavicino (q. v.). See Theiner, *Acta genuina Œcumenici Concilii Tridentini* (2 vols. Leip. 1874); Calenzio, *Documenti inediti e nuovi lavori letterarii sui Concilio di Trento* (Rome 1874); Maynier, *Étude Historique sur le Concile de Trente* (Par. 1874); and Dollinger, *Ungedruckte Berichte und Tagebücher zur Geschichte des Koncils von Trient* (vol. i. Nordling. 1876).

Trenton, capital of the State of New Jersey, U.S., 56 miles S.W. of New York, and 27 N.E. of Philadelphia by rail. It stands on the Delaware, which is here crossed by two fine bridges. T. is well built on elevated ground, and contains a State-capitol, 29 churches, including 8 Methodist Episcopal and 6 Presbyterian, 5 banks, a public library, 4 daily, and 5 weekly newspapers. It has the largest crockery factories in America, and an extensive manufacture of iron in all its branches, employing 2000 men, and producing £1,500,000 worth of goods annually. Its wool and brick industries are also large. Pop. (1876) 22,874. T. was taken by Washington in a night attack, 25th December 1776.

Trepan'. See TREPHINE.

Trepang'. See HOLOTHURIA and BÊCHE DE MER.

Trephine' and Trephining (from Gr. *trupaō*, 'I bore'). The 'trephine' or 'trepan' is a small cylindrical or circular saw, with a centre pinon which it works, and is used by surgeons for the removal of portions of bone. 'Trephining' is practised on the skull in cases of fracture; (1) when a portion of the bone is depressed and encroaches on the cavity of the skull, producing compression of the brain, and the fragment cannot otherwise be raised; (2) for punctured fractures by which the inner table is splintered, separated from the outer table, and lying loose on the dura mater; and (3) for effusion of blood, or of inflammatory products, between the bones and membranes, or between the latter and the brain, when the effused fluid may be evacuated by the opening.

Tres'pass is generally any act of one individual by which another is injured in person or property; but in the limited and common acceptance, it signifies an entry by one individual into the ground of another contrary to the owner's will; every man's ground being in the eye of the law either enclosed by a fence or imaginary line. The owner of cattle is answerable for damage done by their T. To enter on land to execute a legal mission, or to pay money or ask payment of it, if there payable or due, is not T.; but see HOUSE. A shopkeeper is not bound to admit any one into his shop, nor to deal with him, but an innkeeper must, if possible, give accommodation and food to those asking for these (see INNKEEPER, LAW AFFECTING THE). If, however, any one misconducts himself in an inn or tavern he becomes a trespasser from the moment of entry. An exclusive interest in the crop or herbage is sufficient to maintain an action for T.; but actual or constructive possession must be proved. If trees are excepted in a lease, the land on which they grow is also excepted; consequently the landlord may maintain an action of T. for breaking his close. It is a common error to suppose that a trespasser can be given into custody and criminally prosecuted; the only recourse which an owner or tenant of lands has against a trespasser being by an action for damage, or in Scotland by Interdict (q. v.). The requisite physical force may be used to expel a trespasser.

T. in Sporting.—The common law of England allows one man to hunt foxes and some other animals over the ground of another, if no material damage is done; but the right must be carefully made use of, and with good temper, for a jury will consider not only the actual damage sustained by a plaintiff, but also any insult which he has been subjected to: thus, in the case of Merest *v.* Harvey, where the defendant ignored the warning of the plaintiff that he was trespassing, and grossly insulted the plaintiff, the jury awarded the latter £500, though he had sustained no pecuniary loss by the trespass. Every T. is *wilful* where the defendant is warned not to come on the land. And every T. is *malicious* when the intent of the defendant is plainly to annoy the plaintiff. In such cases the judge is bound by statute to award *full costs* to the plaintiff. See POACHING.

Tress'ure, in heraldry, a diminutive of the Orle (q. v.), and half its breadth. It is usually borne double, decorated with fleurs-de-lis (the alternate ones reversed), and blazoned either a 'double T. fleury,' or 'fleury counter-fleury.'

Trevel'yan Experiment, so named from the person who first carefully studied the phenomenon, beautifully illustrates the transformation of heat into sound. When a shovel-shaped block of iron or copper, after being heated to a considerably high temperature, is poised delicately upon a cold lead support so as to press nearly equally on two points separated by a groove, a sound more or less musical is frequently heard. The explanation, as given by Faraday, is that the heated 'rocker' rarely comes in contact with the two points of support simultaneously. Hence the one which is first touched is first heated, and the metal at that point expanding tilts the rocker over upon the other point. Here the action is repeated, and the rocker is tilted back again upon the first point, the metal near which has had time to con-

tract, and is in readiness to repeat the process. The successive impacts accompanying this rapid tilting action combine to form a musical note, which may be varied in pitch and intensity by loading the rocker, or in any way altering its moment of inertia.

Trevel'yan, Sir Charles Edward, Bart., K.C.B., a son of the late Archdeacon T. of Taunton, was born in 1807, educated at the Charterhouse and Haileybury College, and entering the East India Company's Civil Service, held important posts under Lords Auckland and Bentinck. His vigorous action promoted the abolition of Indian transit and town dues, and the introduction of educational institutions on a European model. In 1840 he was appointed Assistant-Secretary to the Treasury, and in 1848 was made K.C.B. for his attempts to relieve the distress caused by the Irish famine. With Sir Stafford Northcote and others he was long engaged in the revision of the civil establishments which led to the Civil Service being thrown open to public competition. He was Governor of Madras from 1859 to 1860, when he was recalled for protesting against the new taxes then imposed by the Government of India, although the Imperial Government accorded him a highly eulogistic vote of thanks. In 1862 he became Financial Minister in India, a post in which he inaugurated important fiscal reform and a vast extension of public works, and which he resigned on account of ill-health in 1865. On his return he published two able pamphlets on army reform, a subject on which he had given evidence before the Royal Commission of 1857. Having subsequently devoted his attention to metropolitan charities, he was created a baronet in 1874. T. married Miss Hannah More Macaulay in 1834, and is the author of *Education of the Irish People* (1838), *The Irish Crisis* (1848), *Purchase System in the British Army* (2d ed. 1867), *The British Army in 1868* (1868), &c. He died 23d March 1879.—**George Otto T.**, son of the preceding, was born at Rothly Temple, Leicestershire, 20th July 1838, and passing from Harrow to Trinity College, Cambridge, graduated as second classic. He entered the East India service by competition, but soon returned from India and was elected Liberal representative of Tynemouth in 1865, and of the Scottish Border Burghs in 1868. In the second Gladstone administration he was appointed Civil Lord of the Admiralty (December 1868), but resigned office in July 1870, being opposed to the Educational Bill of the ministry. He strongly advocated, in and out of Parliament, a sweeping army reform, including the abolition of purchase, effected in 1871. The Volunteer movement had his active support, and he opposed the Regimental Exchanges Bill of 1875. With impetuous rhetoric and fiery invective he has severely criticised the Conservative foreign policy, declaring that war with Russia was only avoided by the resignation of 'the two brave peers' (Carnarvon and Derby), and that, apart from the question of justice, the Afghan War was opposed to the interests of our Indian Empire. On February 22, 1878, he moved the resolution on the extension of the County Franchise, which was lost by fifty-two votes. T.'s literary works comprise *Letters from a Competition Wallah* (new ed. 1866), *Cawnpore* (1865), *Ladies in Parliament and other Poems* (1869), and *Life and Letters of Lord Macaulay* (2 vols. 1876; 2d ed. 1877).

Treves. See TRIER.

Trevi'sa, John, born in Cornwall about the middle of the 14th c., was educated at Queen's College, Oxford, where he was a friend of Wiclif's, became vicar of Berkeley in Gloucestershire, and canon of the collegiate church of Westbury. He is said to have died in 1412. T. spent most of his leisure in turning Latin books into English. His chief works are a translation of Higden's *Polychronicon* (1387), one of the earliest specimens of English prose, of Occam's *Dialogue between a Soldier and a Clerk*, and of *Bartholomæus de Proprietatibus Rerum*, which last, a very mine of rare English words, stands in the list of proposed reprints of the Early English Text Society. Caxton said that T. had also translated the Bible; but his version, if it ever existed, is not known to be extant.

Trevi'so, a town of N. Italy, capital of the province of the same name, on the Sile, 18 miles N. of Venice by rail. The still unfinished Duomo of St. Pietro, with its five towers, dates from the 12th c., and contains paintings by Titian, Pordenone, &c. The Gothic church of St. Niccolo, the theatre, the prison, the courts of justice, and the town-hall, are the chief buildings of interest. There is a library of 30,000 volumes. Silk manufactures are carried on. Pop. (1876) 28,496. T., the ancient *Tarvisium*, did not come into notice till the fall of the Western Empire, since which time it has always been important. Revolutionary movements against Austrian dominion broke out here in 1848.

Trev'or, Sir John, (1) a Secretary of State in the reign of Charles II., and son-in-law of John Hampden, was the eldest son of Sir John T., of Trevallin, in Denbighshire, and was born in 1626. Both father and son were 'halters in the Rebellion, and adherers to the usurper.' The father sat in the Long Parliament, but favoured the Restoration, while the son became a gentleman of the bedchamber to Charles II., and was despatched in 1668 as special envoy to France. On his return he was knighted, and in September appointed to be a Secretary of State, an office which he held until his death. In consequence of his opposing the French policy recommended by the Duke of York, he lost his influence, was ousted from the cabinet in 1670, and found himself 'merely in the skirts of business.' He died one year before his father, May 28, 1672.—(2). Speaker of the House of Commons under James II. and William and Mary, was born in 1633. His family was connected with that of the preceding, and he himself was, by his mother, cousin to the infamous Jeffreys. His rise was rapid through the influence of his powerful relative, and he was knighted, 1671, became king's counsel, 1678, member of the House of Commons, 1679; Speaker, May 1685; Master of the Rolls, October 20, 1685, and a member of privy council, July 6, 1688. After the Revolution, he obtained the favour of William III., and was engaged by him to bring over by bribes the more obstinate members of the House of Commons, of which he was again elected Speaker, March 20, 1690. For some years he held this position, until, in March 1695, the corrupter of others was discovered to have been himself corrupted; and having been found guilty of receiving bribes by a Parliamentary committee, he had the mortification as Speaker of putting to the House the question of his own shame, and, in declaring the issue of the vote, of publishing his own guilt. He never returned to the House, and was, a few days later, formally expelled. He retained the position of Master of the Rolls for the remaining twenty-two years of his life, 'to the great encouragement of prudent bribery for ever after.' He died May 20, 1717.

Trian'gle, in geometry, is a figure bounded by three sides, and therefore possessing three angles. A *rectilineal* T. is a plane figure contained by three straight lines, according to the relations of the length of which the T. is distinguished as equilateral, isosceles, and scalene. The equilateral T. has all its sides equal, the isosceles two of its sides equal, and the scalene all its sides unequal. The sum of the three angles is equal to two right angles; hence two of the angles at least must be acute, *e.g.*, each less than one right angle. When one of the angles is obtuse, the T. is called an obtuse-angled T. The sum of any two of the sides is always greater than the third, and of three given lines which satisfy this condition only one definite T. can be formed, so that two triangles which have their sides equal each to each must be equal to each other in every respect. The area of a T. is equal to the product of the length of any side into the length of the perpendicular upon it from the opposite angle; hence triangles upon the same base and between the same parallels, being thus of the same height, are equal in area. If one or more sides are curved, the T. is curvilineal. Such, for instance, is the sector of a circle, bounded by two radii and the intercepted arc. The most important of all curvilineal triangles is the *spherical T.*, which is formed by the mutual intersection of three great circles upon the surface of a sphere. The angles are measured by the inclinations of the tangents to the corresponding great circles at the angular points, and their sum is greater than two right angles by a quantity known as the *spherical excess.* This excess, multiplied by the square of the radius of the sphere, gives the area of the T. When the radius of the sphere is infinite, the spherical excess vanishes, and the T. becomes a plane rectilineal T.

Trian'gle of Forces, the name given to the proposition in statics, which asserts that, if three forces meeting at a point are equal and parallel to three sides of a triangle, their effects balance, and equilibrium is maintained. The *polygon of forces*

is the name of a more general proposition of precisely the same nature.

Trian'gular Numbers. See FIGURATE NUMBERS.

Triangula'tion is the method by which a large tract of the earth's surface is surveyed, and consists in choosing positions which may be easily observed from a number of other surrounding positions. The distance between two of these is carefully measured, and then by careful measurement of angles the necessary elements of the network of triangles formed by joining contiguous pairs of the chosen points are supplied. The area of the district is thus estimated; or the results may be used to measure the length of an arc of meridian with a view to determining the dimensions of the earth. The triangles are sufficiently small to be considered *individually* plane triangles; but when they are combined, correction must be applied for their sphericity. See SURVEYING.

Tri'as, in geology, is the series of rocks which lie above the Permian and below the Jurassic formations, thus forming the lowest or oldest subdivision of the Secondary or Mesozoic group. It originally received its name from the German geologists, owing to its readily admitting, as developed in that country, of a separation into 3 well-marked groups, as follows:—

Germany.	*England.*
Keuper.	Saliferous marls and sandstones.
Muschelkalk.	Wanting.
Bunter Sandstein.	Reddish sandstones and conglomerates.

Of these three German formations the first attains in certain localities a thickness of about 1000 feet, and its most remarkable members are the St. Cassian or Halstadt beds, which occur on the flanks of the Austrian Alps. They contain evidences of a rich marine fauna, which helps in many ways to bridge over the gulf between the Palæozoic and Secondary series. The Muschelkalk or 'shelly limestone' is wanting in England, and contains, among other marine fossils, an immense profusion of the *Encrinus liliiformis* or 'Lily Encrinite.' The Bunter Sandstein or 'variegated sandstone' is well seen in the Vosges, and also in the Hartz mountains, and is noteworthy for its numerous remains of fossil plants. Many reptilian remains have been obtained from Triassic rocks, and the oldest known mammal, viz., *Microlestes*, is also from the Upper T. Among the British representatives of this formation are the rock-salt beds of Cheshire, &c.; and the sandstones of Connecticut, with their footprints of birds and mammals, are also referred to the T.

Tribe'ni, 'the confluence of three rivers.' Such a spot is peculiarly sacred in Hindu mythology. The most frequented places of pilgrimage which bear this name are (1) in the district of Hoogly, Bengal, at the junction of the Hoogly river with the Jamuna and the silted-up bed of the Saraswuttee; (2) the town of Allahabad, where the Ganges and Jumna meet, and the third stream is imaginary; (3) where the Gunduck river and two of its affluents debouch from the mountains of Nepal on to the plains in the British district of Chumparun.

Tribonia'nus, a Roman jurist of whom little more is known than that under Justinian (q. v.) he held the posts of quæstor, consul, and master of the offices, and from 528 to 533 A.D. took a principal part in the compilation of the Code (q. v.) bearing that emperor's name. Temporary disgrace (531), arising out of the revolt of Nicæa, was followed by T.'s restoration to his former honours, which he retained down to his death in 545.

Trib'unes, originally representatives of tribes—*e.g.*, of the Ramnes, Tities, and Luceres, in the later days of the Roman republic—were officers invested with a variety of functions. The plebeian T. (*tribuni plebis*) were first created after the secession of the plebeians to the Mons Sacer (494 B.C.), could not be chosen from the patrician order, and varied in number from two to ten, any one of whom might impose a veto on his fellows' actions. Set up as an opposition magistracy to the consuls, as an embodiment of plebeian rights, the T., whose persons were inviolate, extended their powers little by little, till ultimately they surpassed all other officers of state, and on the negatory *potestas tribunicia* the imperial dignity itself was chiefly based. Consular T. were three magistrates appointed in 444 B.C., a number afterwards raised to eight, who might be either plebeians or patricians, and who till 367 B.C. occasionally supplied the place of Consuls (q. v.); and legionary T. were six officers of a Legio (q. v.) who took the command by turns.

Trichi'asis (Gr. *thrix*, 'a hair') is an inversion of the eyelashes. Usually three or four of the hairs are turned towards the eyeball, and excite a pricking sensation, creating great irritation. There is a constant watery state of the eye, and a disposition to rub it, the irritation setting up an inflammatory state. The cure consists in removing, one after the other, all the inverted and misplaced cilia by means of forceps without teeth, the surface being merely roughened. When a considerable number of the cilia are inverted, extirpation of a fold of skin may be necessary, or extirpation of a strip of the integuments, including the bulbs of the cilia. When several cilia in a group are inverted, a triangular or narrow wedge-shaped piece of the whole thickness of the lid, including the eyelashes, may be removed and the edges brought together with sutures.

Trich'ina (from Gr. *trichinos*, 'pertaining to hair'), the name given to a small Nematoid worm. In an asexual state it occurs in the muscles of warm-blooded Vertebrate animals, in whose digestive system it attains sexual maturity. As in other Nematoids, the sexes in T. are distinct. The average length of the female is from $\frac{1}{12}$th to $\frac{1}{8}$th of an inch. The male is much smaller than the female. In its sexually immature condition, the T. exist within little sacs or capsules, within the muscular tissues of their hosts. It was in this condition that the T. was first discovered in the dissecting-room of St. Bartholomew's Hospital, London, in 1835; Mr. Wormald, the then demonstrator of anatomy, sending the specimen to Owen, who named the organism. Sir James Paget investigated the subject independently about the same date. It was not, however, until 1855-60 that the true history of the T. was determined. Virchow and Leuckart then showed that the T. was not, as had been supposed, the immature form of some other Nematoid. By feeding animals on trichiniased flesh they developed young T. in large numbers, and traced their history, about to be described. As the T. lie coiled up within their cysts in the muscles, each measures about $\frac{1}{75}$th inch in diameter, and about $\frac{1}{78}$th inch in length. These cysts are liable to undergo calcareous degeneration after a time, this process resulting in the destruction of the contained worm. The number of T. which may find lodgment in the muscles is sometimes enormous. Leuckart calculated that a single ounce of cat's muscle contained no less than 325,000 of these parasites, whilst in a human host so affected over 20,000,000 might be contained. The *development* of the T. is a subject which, from its bearings on human health, naturally attracts much attention. When a portion of T.-infested flesh—say of the pig—is eaten by man, the cysts are dissolved, and the T. are liberated within the stomach of the human subject. In a short period these immature T. become sexually perfect. They develop generative organs, and produce young *viviparously* in large numbers. The young next begin to seek a lodgment for themselves in the muscles, and in that search bore their way through from the alimentary system to the muscles. During this latter process the infested subject experiences severe pains, the nature of these pains being unsuspected when the first cases of *Trichiniasis* were observed. The pains were supposed to be due to acute rheumatism, while the suddenness of the attack was even suggestive of poisoning. Once situated in the muscles, the young T. develop capsules or cysts around their bodies, and present the appearance assumed by their progenitors in the muscles of the pig. This young brood of T. can of course undergo no further development unless the muscles of man be eaten by some other warm-blooded quadruped, in which case the cycle of development just described would be again passed through. Davaine's experiments seem to prove that adult T. soon perish in cold water, and do not long appear to survive the death of their host. They may, however, remain tolerably active in the larval condition in putrid meat or in flesh that lies decomposing in water, and thus infection may be conveyed to pigs or to other animals which drink the infested fluid.

Trichin'iasis is a disease produced by the presence of trichinæ within the human system, and within the bodies of other animals liable to infestation. The first well-marked case occurred at Dresden in 1860, the patient being a servant-girl, who

was admitted to hospital, having taken ill on January 12. The patient died after a short illness characterised by symptoms of lung-inflammation, rheumatic pains, spasmodic contraction of the limbs, and other abnormal conditions, indicating some obscure lesion the nature of which was imperfectly understood. It was discovered at the *post-mortem* examination, that in the muscles of this patient numerous larval trichinæ were encysted, whilst mature trichinæ were found in the intestines. Previously to her illness the patient had assisted in making pork sausages, and had eaten some of the meat in a raw state, this fact accounting for the trichinose infestation. Zenker, who records the case, recognised in the symptoms those of a new lesion caused by the presence and development of trichinæ within the tissues of man. The preliminary symptoms are loss of appetite, prostration, and general debility, which continue for about a week. Pains of a rheumatic character, œdema, or dropsy and swelling of the limbs, along with fever, next occur, indicating the progress of the trichinæ brood from the digestive system to the muscles. This stage of T. is unquestionably the most dangerous. It is during the migration of the trichinæ from the alimentary canal, and as they force their way through to the muscular system, that the patient experiences the most severe symptoms and stands in greatest danger. Severe pains are experienced at this period in a typical case of T., and even breathing may be executed with difficulty owing to the lesions of the muscles. Diarrhœa is also prevalent, the symptoms on the whole bearing a resemblance to those of gastric fever. In about four weeks after the commencement of the symptoms, the disease begins to abate. In severe cases the diarrhœa may continue, and often aids a fatal issue, arising from the prostration, together with the total derangement of the secretions. In an acute case of T., death has been known to occur as early as the fifth day of the disease, while a fatal issue has been allayed as late as the forty-second day. Epidemics of T. have chiefly occurred on the Continent, where the habit of eating smoked and uncooked sausages is widespread. At Hattstadt, in Oct. 1863, an epidemic of this disorder affected 158 persons, a fatal result occurring in 28 cases. An examination of pig's flesh shows that trichinæ are frequently found in the muscles. No external signs in the pig afford evidence of the presence of trichinæ, and the microscopic examination of the flesh is the only true test of infestation. A temperature of 167° F. is sufficient to kill trichinæ larvæ, and the prohibition against uncooked or imperfectly cooked animal food of all kinds, is to be rigorously insisted upon in the rules of hygiene. The *treatment* of T. appears to consist in active purgation in the early stages of the disease, with the view of removing the worms from the intestine, calomel being the purgative usually given. German statistics fortunately show a decline in the number of cases of T.—from one out of every 2000 pigs in 1876 to one in every 2800 in 1877. The absolute number of trichinose pigs in the latter year was 701 out of 2,057,273; and 138 persons were known to have suffered from T. On the other hand, from the *Lancet* of 22d February 1879 we learn that German investigators have made the disagreeable discovery that the bacon and pork imported into Europe from the United States is, contrary to the belief hitherto entertained, not at all free from the presence of the muscle-worm. There can be no doubt that increased caution in the use of pig's flesh is necessary on the part of the community.

Trichinop'oly (*Trichinapalli*), the chief town of the district of the same name, Madras Presidency, British India, on the right bank of the Cauvery river, 320 miles S.S.W. of Madras by rail. T. is celebrated for its fort, which was built (*circa* 1570) by a native prince of Madura, and formed the object of all the wars between the English and the French in S. India between 1749 and 1763, when Clive first rose to fame. The fort occupies a granite cliff rising 500 feet above the plain, crowned with a small pagoda, with a cave temple hewn out of its S. face. The walls have recently been levelled, and the moat filled up, and the whole is now being laid out as a boulevard. T. is the headquarters of the Brigadier commanding the S. Division of the Madras army. There are barracks for European troops and artillery. In the church is the tomb of Bishop Heber, who died here in 1826. The manufactures include jewellery, paintings on talc, paper and pith ornaments. The silver filigree work and the cigars are especially famous. Pop. (1871) 76,530.—The *district* of T., which lies on both banks of the Cauvery, landward of Tanjore, has an area of 3515 sq. miles; pop. (1871) 1,200,408. It abounds with gneiss, granite, iron-ore, and limestone. The products are rice, cotton, sugar, oil-seeds, and tobacco. The exports include saltpetre, hewn stone for building, and grindstones. The imports are English piece-goods. Besides the manufactures of the town, basket-boats are made of wicker-work covered with hides. This tract contains several *anicuts* or weirs, constructed across the river Cauvery, some by ancient Hindu kings, and others by Sir Arthur Cotton (1836-45). These irrigate 600,000 acres, and are considered the most successful works of their kind in India.

Trichoceph'alus (Gr. *trix*, 'a hair,' and *kephalē*, the 'head'), a genus of nematoid worms, inhabiting the *cæcum* or first portion of the large intestine of man. This parasite is rare in England, but is said to be common in France. The average length is from 1½ to 2 inches. The front part of the body is exceedingly slender. The species inhabiting man is the *T. dispar*. The development of the T. is very imperfectly known.

Trichop'tera. See CADDICE.

Trick'ing, in heraldry, is the representing by writing of the tinctures of a coat of arms sketched in outline with pen and ink.

Triclin'ium (Lat., from Gr. *triklinos*, from *tri*, 'three,' and *klinein*, 'to lie down'), among the later Romans the dining-room where guests were received, containing a square table surrounded on three sides by as many low couches for reclining, while the fourth side was left open to the access of attendants.

Tric'olour, the national flag of France, which, composed of blue, white, and red vertical strips, was taken as the badge of the National Guard at the commencement of the Revolution. Germany, Italy, Belgium, Holland, &c., have also since adopted tricolours.

Tridac'na, a genus of *Lamellibranchiate* mollusca, including the forms familiarly named 'Clams.' The *T. gigas* or Giant Clam is the best-known member of this genus, which forms also the type of a family (*Tridacnidæ*). In this group the shell is equivalve and the ligament external, and the animal may be attached or free. The mantle lobes are closely united, and the foot is finger-like. The surface of the shell is ribbed, and its margins are toothed. *T. gigas* may attain a very large size, the shells being known to attain an occasional weight of 500 lbs. They are sometimes used as fonts in Roman Catholic churches.

Tri'dent (Lat. *tridens*), an instrument in the form of a fork with three prongs, used by the ancients in driving oxen and catching large fish. In Greek mythology the T. is the symbol of Poseidon's dominion over the sea, corresponding to the sceptre of other gods.

Trienn'ial Prescrip'tion, in Scotch law. See PRESCRIPTION.

Tri'er (Fr. *Trèves*), a town of Rhenish Prussia, 30 miles N.E. of Luxemburg by rail, lies amid vineclad hills of ruddy sandstone, on the right bank of the Mosel, which is here spanned by an eight-arched Roman bridge. The 2d c. *Porta Nigra* (93 feet high by 115 long) served as a church from 1035 to 1817, when it was reconverted to a statelier city gateway than any France or Italy can boast. There are Roman baths too, an amphitheatre, and a basilica (restored into a noble Protestant church, 1856); while the cathedral itself is mostly Roman, but from its multitude of later styles is rather quaint than beautiful. Measuring 320 by 140 feet, it contains among other relics the Holy Coat (q. v.), and is connected by a cloister with the exquisite little Liebfrauenkirche (1227 43). More noteworthy than any of these is the Igelsaule or Heidenthurm, some 4 miles from the town, a graceful monumental column, 71 feet high, sculptured with spirited bas-reliefs, and dating from the 2d c. The Rathhaus, a Gothic building of the 15th c., has been turned into an hotel, a Roman *propugnaculum* into a coach-house. To modern times belong the gymnasium, containing a museum and town library of 100,000 volumes, the *realschule*, hospitals, &c., and on the opposite bank the Mariensaule, surmounted by a colossal figure of the Virgin. T. has manufactures of woollen, cotton, and linen stuffs, of hats, tobacco, carpets, and leather, and carries on an important trade in cattle, wood, and the wine of the surrounding district. Pop. (1875) 20,027, of whom 2800 are Protestants. The capital of the Treviri and *Augusta Trevirorum* (56 B.C.) of Cæsar, T. from the 3d c. was a frequent residence of the Roman emperors, and under Constantine (306-37) as capital of Gaul rivalled Rome itself. It never, however, wholly recovered the Germanic invasions of the 5th c., though as the seat of bishops (since 329) and

later of electoral archbishops, who down to 1801 bore the title 'Archchancellor of Gaul and the Kingdom of Arles,' it remained a place of consequence. The removal of the last Elector to Koblenz (1786), and the reduction of T. to *chef lieu* of the French department of the Saar (1801–14), left it a mere cathedral city; and, made over to Prussia (1815), it is now 'a quiet, old-fashioned town, with a body of Roman remains far more numerous and varied, if not individually more striking, than any other place N. of the Alps can show.' See Freeman's *Augusta Trevirorum* in *Historical and Architectural Sketches* (Lond. 1876), and the local histories of Haupt (2 vols. Trier 1822), Braur (Trier 1854), Leonardy (Saarlouis 1871), and Wilmowsky (2 vols. Trier 1873–74).

Triëst (Slav. *Tèrst*, Ital. *Trieste*), the principal seaport of the Austro-Hungarian monarchy, and an imperial free town, on a crescent-shaped bay at the head of the Adriatic to the S. of the Triesener Karst, 90 miles S.W. of Laibach by rail. It is the terminus of the railway from Vienna (*Sudbahn*) and of that from Venice, and an important place for the transit trade between the East and the manufacturing centres of Europe. The territory belonging to it, which is enclosed by the Austrian Küstenland (q. v.), has an area of 90 sq. miles, and a pop. (1870), including the town, of 123,093. The old town, built in the Italian style, is huddled together on the slope of the Schlossberg and around the old harbour, and is connected with the new town or Theresienstadt to the E. by the broad, elegant Corso, which opens into spacious squares, adorned with fountains and monuments. To the S.E. of the old town lies the suburb of Josephstadt, and beyond the Theresienstadt that of Franzenstadt, separated by the Torrente, which is crossed by several bridges. The harbour is really an open roadstead, but there are several moles, and the bay of Servola, near Muggia, is the only naval station of Austria. The directors of the Sudbahn, who enjoy a monopoly of the inland communication which for years has been sapping the local trade, have, in connection with their vast through traffic, constructed a spacious private harbour to the N. of T. (completed 1877). The sea-approach to T. is unobstructed by sandbanks, but shipping is exposed to the fury of the Bora or north-east winds. The defences comprise, besides the castle on the Schlossberg, a fort and several harbour batteries. T. is the residence of the Bishop of Capo d'Istria, and its cathedral of St. Justus, crowning the hill, is a singularly interesting double basilica of the 14th c. formed out of a temple of Jupiter, and containing imbedded in its walls pilasters, columns, entablatures, trophies, &c., of the older edifice. The other ancient relic of T. is a small Roman arch (*Arco di Riccardo*), apparently triumphal, showing still on one side its Corinthian pilasters. Other churches are those of St. Peter (1367) with a clock-tower, Santa Maria Maggiore (1627), San Antonio Vecchio, the Greek San Niccolo, the Synagogue, &c. The Tergesteum, a vast quadrangular building of 1842, contains the Exchange, the Austrian Lloyd's offices, a bazaar, grand concert and ball rooms, &c. The finest secular edifice in the old town is the Old Exchange, in front of which are the noble statue of Leopold I., on a marble column 76 metres high (1661), and Mazzoleni's fountain with marble groups (1751). Other monuments are those of Karl VI. on the Piazza Grande, and Ferdinand I. in front of the cathedral, erected 1560. There are schools of navigation, an upper gymnasium, museums of science and antiquities (important Roman collections), a zoological collection, several libraries, &c. T. has no fewer than thirty-four public squares, and in and around it are many imposing mansions and elegant villas. In 1876 the imports amounted to £13,919,490, and the exports to £9,789,637, showing a decided falling off on previous years. The value of Austrian imports was £7,612,176, of British £3,054,763; of Austrian exports £6,614,970, and British £1,132,418. The chief imports are coal, fruits, iron, machinery, cotton goods, colonial produce, petroleum, olive oil, and spirits. There entered the port (1876) 7851 vessels of 985,682 tons, and cleared 7828 of 985,044 tons. T. has considerable shipbuilding, and manufactures soap, cordage, rosoglio, white-lead, leather, &c. Pop. (1870) 70,274, extremely mixed, but mostly Italian-speaking. *Tergeste*, a place of importance in Roman times, had a peculiar destiny standing on the border-land of Italy and Illyria. It was included in the dominion of Theodoric and in Justinian's recovered empire, but it never fell under the Lombard rule. It remained with the lords of Constantinople and Ravenna till it became part of the kingdom of the Karlings. The history of T. is simply that of an Italian city, till by the treaty of Turin in 1381 its independence is allowed by the contending powers; but in 1382 it took the seemingly strange step of submitting to the lordship of Leopold, Duke of Austria. The lordship of T. was at first only an over-lordship, but the bond gradually came to imply bondage, and T. has ever since remained Austrian in allegiance, save during the chaos of the elder Bonaparte's days. The *Italia irredenta* movement caused some disturbances in 1878. See the local histories of Löwenthal (2 vols. Trieste 1857) and Scussa (Trieste 1864), also Freeman's *Historical and Architectural Sketches* (Lond. 1876).

Tri'fle, a fancy confection or dish composed of a basis of fine crisp paste soaked in white wine, over which a layer of custard and cream is placed, the whole being surmounted with a light, delicate white froth, prepared by whisking up white of egg with cream and sugar. The above may be taken as a type of similar preparations which vary endlessly in their combinations.

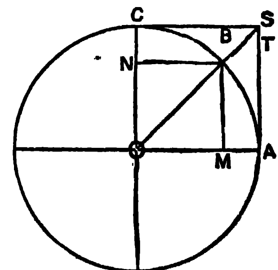
Trifo'lium. See CLOVER.

Trifo'rium, in ecclesiastical architecture, an arcade surmounting the pier-arches that separate the nave from the aisles. It derives its name from the *three* arches or *openings* (*triforia*) resting upon columns, of which originally it always consisted.

Trigg'er. See BREECH-LOADING ARMS.

Trigg'er-fish (*Balistes*), a genus of fishes belonging to the order *Teleostei* (q. v.) and to the sub-order *Plectognathi* (q. v.), and deriving their popular name from the peculiar nature of the first ray or spine of the first dorsal fin. This ray is very strong, and remains in an erect position until the second ray is depressed, when it falls like the trigger of a gun The T. occurs in tropical seas, and is allied to the urchin-fish.

Trig'la. See GURNARD.



Tri'glyph, an ornament used in the Doric frieze, and consisting of three vertical angular channels or flutes, separated by narrow flat spaces called *femora*. In the Roman examples it is placed over the centre of the column; in the Greek, at the angle of an entablature close up to the angle.

Trigo'nia, a genus of *Lamellibranchiate* Molluscs. In this group, which is typical of the family *Trigoniadæ*, the shell is three-sided and equivalve, and the foot is long and bent. T. itself is represented by a few living species found in Australian seas. Other genera are *Myophoria*, found fossil in Triassic rocks, and *Axinus*, extending in its palæontogical range from the Upper Silurian to the Trias, and specially found in rocks of Permian age.

Trigonoceph'alus, a genus of *Viperine* snakes belonging to the family *Crotalidæ* or that of the Rattlesnakes, and nearly allied to the genus *Craspedocephalus*, of which the dreaded Fer-de-lance (*C. lanceolatus*) of Brazil is a familiar example. The tail in T. ends in a spine, instead of a rattle as in the *Crotalus*, and the head is covered with prominent *scorb* or shields. The *T. rhodostoma* of Java preys on frogs and lizards, and is highly venomous.

Trigonomet'rical Sur'vey See GEODESY; ORDNANCE SURVEY; SURVEY.

Trigonom'etry (Gr. *trigōnos*, 'three-cornered,' and *metron*, 'measure') is the branch of mathematics which, though really based upon the relations subsisting between the angles and sides of a triangle, embraces the consideration of all periodic functions, of which the so-called *circular functions* are typical examples. Let AOB be an angle at the centre of the circle ABC, whose radius is unity. OC is at right angles to OA; while B is taken anywhere on the circumference, between A and C for convenience. AB is evidently the circular measure (see CIRCLE) of the angle AOB. Draw BM parallel to OC and meeting OA in M; and BN parallel to OA and meeting OC in N. Produce OB till it meet the tangents through A and C at T and S respectively. Then the following nomenclature is adopted:—BM is called the *sine* of the

arc AB or of the angle AOB, AT the *tangent*, and OT the *secant;* while the lines BN, CS, and OS, are known as the *cosine*, *cotangent*, and *cosecant* of the angle AOB, since they are obviously the sine, tangent, and secant of the complementary angle BOC. If the circle is not of unit radius, these lines no longer represent the functions so named, which must in such a case be expressed as the ratios of these lines to the radius. Thus

$$\frac{BM}{OA} = \text{sine AOB}; \quad \frac{OM}{OA} = \text{cosine AOB, \&c.}$$

From simple geometry we have the relations AT : OA = BM : OM, and OT : OA = OB : OM, which give other expressions for the tangent and secant; and similar substitutions hold for the cotangent and cosecant. Hence it is evident that the various circular functions of a given angle may be represented by the ratios subsisting between the sides of a right-angled triangle, one of whose angles is the given angle. Thus, representing the angle AOB by the symbol a, and the sides OB, OM, and BM by a, b, and c respectively, the various relations are thus expressed—

$$\sin \alpha = \frac{c}{a}, \tan \alpha = \frac{c}{b}, \sec \alpha = \frac{a}{b}$$

$$\cos \alpha = \frac{b}{a}, \cot \alpha = \frac{b}{c}, \operatorname{cosec} \alpha = \frac{a}{c}$$

From these numerous mutual relations between the several functions may be deduced, as for example

$$(\sin \alpha)^2 + (\cos \alpha)^2 = 1, \tan \alpha = \frac{\sin \alpha}{\cos \alpha} = \frac{1}{\cot \alpha}.$$

The next point which calls for special consideration is the periodicity of these functions. Imagine B to move uniformly from coincidence with A right round the circle in the positive direction, *i.e.*, contrary to the direction of the hands of a watch, until it coincides with A again. During the process, the angle α grows from zero to four right angles, from o to 2π; but how does the sine vary? It begins with zero, and grows gradually till the angle reaches the value of $\frac{\pi}{2}$, or one right angle. At this point the sine is unity, and then falls off to zero as the angle approaches π or two right-angles. Here it passes through zero and becomes *negative*, still continuing therefore to diminish algebraically until, when the angle is $\frac{3\pi}{2}$ or three right-angles, it reaches its minimum, -1, and then approaches zero again as the angle approaches 2π or four right angles. While the point B makes one complete revolution, the value of the sine oscillates between $+1$, and -1, passing through zero twice. In the first and second quadrants it is positive, in the third and fourth negative. The cosine goes through a very similar cycle, except that its value is $+1$ when the angle is zero, -1 when the angle is π, and vanishes when the angle is $\frac{\pi}{2}$ and $\frac{3\pi}{2}$. The cosine is therefore positive in the first and fourth quadrants, and negative in the second and third. The tangent grows from zero to *plus* infinity in the first quadrant, continues to grow (in an algebraic sense) from *minus* infinity to zero in the second, from zero to *plus* infinity in the third, and from *minus* infinity to zero in the fourth. It is therefore *positive* in the first and third quadrants, and *negative* in the second and fourth. The cosecant, secant, and cotangent, being the reciprocals of the sine, cosine, and tangent, follow the same rules as to signs, &c. This question of *sign* is one of extreme importance in all trigonometrical theorems, for which, however, we must refer to the standard treatises by Todhunter and others upon the subject. The simpler theorems, such as the sides of a triangle are proportional to the sines of the opposite angles, the area of a triangle is measured by the product of any two sides into the sine of the contained angle, &c., are directly deduced from the fractional expression given above for the several functions. In treating of spherical triangles (see TRIANGLE), other and more complex relations between the connected functions hold, the treatment of which forms a peculiar branch of T., known as spherical T. The importance of these functions in the practical solution of all mathematical problems other than the very simplest has necessitated the tabulation of their values for all angles between 0° and 90°. For larger angles the values reproduce themselves according to a simple periodic law. In the best tables, such as Chambers' *Mathematical Tables*, the logarithms of the values are tabulated to facilitate calculation.

Trik'hala (the *Trikkē* of Homer), a town of Turkey, in the vilayet of Janina, on the Peneius, 34½ miles W. of Larissa. It has a castle, ten Greek churches, seven mosques, two synagogues, and a Greek college, is the seat of a bishop, and carries on dyeing, tanning, and cotton manufacture. Pop. 10,000. T. anciently possessed a famous temple of Æsculapius.

Triku'pis, Spirid'ion, a Greek statesman and historian, was born at Missolonghi in 1791, and in 1810 was sent to study in London by Lord North, who as Governor of the Ionian Isles chose him for private secretary. Throughout the Greek War of Independence, excepting the presidency of Capo d'Istria, he filled a number of important posts, and under Otto I. was three times envoy to London (1835-38, 1841-43, 1850-62), minister of foreign affairs and public instruction (1843), and president of the senate (1844-49). On Otto's deposition T. withdrew from politics, dying at Athens, February 24, 1873. His *Historia tēs Hellēnikēs Epanastaseōs* (4 vols. Lond. 1853-57; 2d ed. 1862) is perhaps the chief literary product of modern Greece, and T. is also remembered for his funeral oration on Byron, and by a spirited Clepht war-song, *Ho dēmos* (Par. 1821). His son, Constantin, belonging to the Radical party, was president of the council (1875-76), and since 1877 has held the portfolio of foreign affairs in Comoundouros' ministry.

Trillia'ceæ, a small natural order of about thirty species, is now reduced to *Trillideæ*, a tribe of the order *Liliaceæ*, and is distinguished by a creeping rootstock, a stem bearing one or two whorls of reticulate-veined leaves, flowers not jointed on the pedicel, styles free, and fruit a berry. The species are natives of N. temperate regions. *Trillium* and *Paris* are the most important genera. The roots of *Trillium* are generally violently emetic, and are occasionally used medicinally in the United States.

Tril'obites, an important order of extinct *Crustacea*, having a trilobed body with a cephalic or head shield, bearing a pair of compound and unstalked eyes. The segments of the chest were movable, but those of the abdomen were united, and formed a caudal or tail-shield. An upper lip or *hypostome* existed. These fossils are characteristic of Palæozoic rocks. They extend from the Upper Cambrian to the Lower Carboniferous. The body had a well-developed 'shell,' to the presence of which the perfect preservation of these animals in a fossil state is due. The most curious fact concerning the T. is the absence of any appendages in a fossil state save the eyes. The division of the back or dorsal surface into three lobes was not universal, being absent in such genera as *Homalonotus* and *Illænus*. The front portion of the body exhibited the cephalic shield, composed of three pieces—one central and two lateral. The central part or *glabella* protected the stomach of the T., and the lateral parts of the shield were named the 'free cheeks.' The second part of the body or *thorax* varied in the number of its rings from two to twenty-six, the latter number being found in *Harpes ungula*. The caudal shield is named the *pygidium*, and was occasionally prolonged to form a spine-like tail. The zoological position of the T. is hard to determine. Their nearest affinities, however, appear to point to the *Phyllopoda*, represented by the brine shrimps, fairy shrimps, &c., or even to the order *Isopoda*, including the wood-lice. The chief genera of T. are *Agnostus*, *Olenus*, *Paradoxides*, *Asaphus*, *Calymene*, *Homalonotus*, *Phacops*, *Lichas*, *Prœtus*, *Acidaspis*, *Bronteus*, *Harpes*, *Cyphaspis*, &c.

Tril'ogy, a series of three tragedies, each in a way complete, yet each a link in a common chain, such as Greek dramatists produced at the Dionysia, and which, when the usual satyric play was added, formed a tetralogy. The *Oresteia* of Æschylus, comprising the *Agamemnon*, *Choëphoræ*, and *Eumenides*, is the only perfect T. preserved to us from classic times; late imitations are Shakespeare's *Henry IV.*, Schiller's *Wallenstein* (1800), and Wagner's *Ring des Nibelungen* (1876).

Trimethyl'amine ($N(CH_3)_3$), an organic compound which is abundantly present in the liquor in which salt herrings are preserved. When methyl iodide is digested with an alcoholic solution of ammonia, a mixture of various organic iodides is produced, among others the iodide of tetramethyl-ammonium, which being sparingly soluble in water is readily separated by crystallisation. The base is then obtained free by treatment with silver oxide, and the tetramethyl-ammonium hydrate ($N(CH_3)_4OH$) so produced decomposes when heated, yielding T., which is gaseous at ordinary temperatures, readily soluble

in water, and possesses a strong alkaline reaction. With acids it forms soluble salts. There is a similar ethyl compound ($N(C_2H_5)_3$), a powerfully alkaline liquid, boiling at 91° C.

Trimm'er, a statesman who trims his sails to every shifting breeze of politics, the title which, coined towards the close of the 17th c., was assumed by Halifax (q. v.) as one of honour.

Trimm'er, Mrs. Sarah, a writer of books for the young, was born at Ipswich, January 6, 1741. Her father, Joshua T., was the author of some works on perspective, and became tutor to the Prince of Wales (George III.) and Queen Charlotte. It was not till 1780, when she was already the mother of a large family, that Mrs. T. published her first work, *An Easy Introduction to the Knowledge of Nature*, but its success was such that she continued till her death to issue similar didactic productions. Many of these supplied a genuine want at the time, and though their value has gradually diminished with the advance of educational appliances, the authoress deserves the gratitude even of the generations which have been enabled to outgrow her works. She died suddenly, December 15, 1810. See *Life and Writings of Mrs. T.* (2 vols. 1814); Mrs. Elwood, *Literary Ladies of England*; and C. M. Yonge, *Biographies of Good Women*.

Trimor'phism. In certain species of plants two different combinations of reproductive organs occur, long stamens and short styles on some individuals and the reverse on others. This is called *dimorphism*, and we have examples in the flax and the primrose. T. is the existence of three different forms, as in the purple loosestrife. Fertilisation, as a rule, takes place between the male and female organs of the *same height*, consequently securing *cross-fertilisation*.

Trincom'alee, a fortified town on the E. coast of the island of Ceylon, commanding the one natural harbour of refuge in the Indian seas. The entrance is nearly landlocked, and there is deep water close to the shore. The town is irregularly built, and is separated from the fortress by an esplanade. It has several pagodas and mosques, two Protestant churches, and one Roman Catholic church, and carries on a regular intercourse with Madras. Pop. 11,447.

Trincom'alee Wood. See HALMALILLE.

Tring, a market town of Hertfordshire, 31¾ miles N.W. of London by rail, on the Grand Junction Canal, has a Perpendicular parish church, 6 chapels, a market-house, mechanics' institute, assembly rooms, &c., whilst in the neighbourhood is T. Park, a seat of the Rothschilds, built for Nell Gwynne by Charles II. Straw-plaiting, sild-throwing, canvas-weaving, and brewing are the chief industries. Pop. (1871) 3283.

Trin'ga. See SANDPIPER.

Trinidad', the most southerly of the W. Indian Islands and a British possession, lies in 10° 2'–10° 50' N. lat., 60° 56'–61° 59' W. long. It has an extreme length of 65 miles, a breadth of 49 miles, and an area of 1754 sq. miles. It is separated from the mainland of Venezuela by the landlocked Gulf of Paria, which is only 9 miles wide at its narrowest part. The N. part of the island is traversed by a range of mountains 3000 feet high and clothed with luxuriant forests, whose trees yield a great variety of useful timbers and ornamental woods. The S. part of the island is less elevated, consisting chiefly of rich valleys. The climate being hot and moist, and the soil extremely fertile, the natural productiveness of the island is very great; nevertheless only a twelfth part of it is under cultivation. In 1874, 49,877 acres were under sugar-cane, 17,828 under cocoa, 17,393 under ground provisions, and 6547 in pasture. The labourers employed are chiefly Hindu Coolies (q. v.), of whom 13,344 were imported in 1871–75. The staple products are sugar and cocoa, but cocoa-nuts, coffee, and cotton are also exported. Deposits of coal and glance pitch are beginning to be worked, and about 16,000 tons of asphalt are annually exported, this substance being obtained floating on the top of a remarkable freshwater lake near La Brea in the S. part of the island. In 1876 the total value of the imports of T. was £1,666,268, and of the exports £1,636,619, and the total tonnage of the vessels that entered and cleared was 516,828. The pop. at the census of 1871 was 109,638, and in 1876 was estimated at 120,000; and in 1875 there were 87 schools, with 7617 scholars. The capital, Port au Prince, is a handsome town of 22,000 inhabitants, built of stone, and connected by rail with Arinca, in the heart of the sugar-producing district, 16 miles distant. T. was discovered by Columbus in 1498, and named from its three conspicuous peaks, was captured from Spain by a British expedition in 1797, and confirmed to Britain in 1802. It is a Crown colony, ruled by a Governor, assisted by an Executive Council of 3 and a Legislative Council of 13 members, all of whom are nominated by the Crown. See L. Borde's *Histoire de T. sous le gouvèrnement espagnol* (vol. i. Par. 1876).

Trin'ity (Lat. from *triunus*, 'three in one'), **Doctrine of the**, viz., that there are three persons in the unity of one Godhead, involves four principal propositions:—(1), That there is but one God, who is indivisible; (2), that the one indivisible divine essence exists eternally as Father, and as Son, and as Holy Spirit; (3), that the distinction between these three is a personal one; (4), that these persons are distinguished as first, second, and third, to express an order indicated in Scripture.

From the beginning of the 2d. c. the objects of the Christian faith were often summed up in a trilogy, the Father, Son, and Holy Spirit, which formed the foundation of the Rule of Faith adopted at the end of that century, which again developed into what is known as the Apostles' Creed. The object of the Nicene Creed (325) was to settle the points regarding the person of the Son raised in the Arian controversy. It merely mentions the Holy Spirit, without declaring anything as to his nature or relations to the Father and Son. The Arians and semi-Arians meantime regarded him as a created being subordinate to the Son, as the Son was to the Father. It therefore appeared necessary that the Church should make some definite statement on the subject. This was done at the Council of Constantinople (381), which added to the Nicene Creed a declaration of the personality and the equal dignity of the Holy Spirit. The shade of subordination of both the Spirit and the Son to the Father implied in merely saying that the Spirit proceeded from the Father was removed by the addition (Council of Toledo 589) of the clause *Filioque* (q. v.). The doctrine owes its completion and establishment to Augustine (354–430), who applied all the powers of his clear and methodical mind to render it supportable to human reason. As thus completed it was minutely defined in the Athanasian Creed (q. v.), which closed up every opening by which a breath of heresy could possibly enter.

Trin'ity, a river which rises in the N. of Texas, U.S., and flows S.E. through a fertile country to Galveston Bay. Its total length is 550 miles, 90 of which are navigable by large vessels.

Trin'ity Coll'ege, Cam'bridge, was founded by Henry VIII. in 1546 upon the site and out of the revenues of Michaelhouse (1324), King's Hall (1337), and other ancient societies. To the sixty fellowships and scholarships of his foundation Queen Mary added twenty scholarships, and at present there are a master, sixty fellows, seventy-four scholars, and sixteen sizars. The scholarships, which are tenable up to the M.A. degree, have a yearly value of from £100 to £30, the sizarships of about £70; and there are further three annual minor scholarships of £75, and three of £50, tenable for three years, besides sixteen exhibitions for scholars from Westminster, St. Paul's, Lynn, Shrewsbury, &c., and numerous prizes. The fellows, with certain exceptions, must take holy orders within seven years after their M.A., and the college may elect professors or other distinguished literary or scientific men to regular or honorary fellowships. The greatest of all the Cambridge colleges, indeed, the largest college in the world, Trinity is more conspicuous for the extent than the special architectural beauty of its buildings. Noteworthy, however, are Nevill's Fountain, the three great gateways by which the three chief courts are entered, the Gothic Hall with its high-peaked roof, the chapel (re-decorated 1875), the library designed by Wren, and containing nearly 100,000 volumes, the Master's Lodge, with its state-rooms, where royalty and the judges are received, and the rich collection of busts and statues of former members—of Newton by Roubillac, Porson by Chantrey, Byron by Thorwaldsen, Barrow, Macaulay, Whewell, Sedgwick, Tennyson, &c. T. C. appoints the masters of Stone, Uttoxeter, and Stevenage schools, holds the patronage of sixty-three livings, and in 1878 had 2038 members of the senate, 3214 members on the boards, and 535 out of the 2485 undergraduates of the whole university. See Arnold's *Oxford and Cambridge, their Colleges and Memoirs* (Lond. 1872).

Trin'ity Coll'ege, Ox'ford, was founded in 1554, on the site of Durham College, by Sir Thomas Pope, of Tithenhanger,

Hertfordshire. It consisted of a president, 12 fellows, and 12 scholars. Both fellowships and scholarships are open, and to the latter (£80) have been added a Blount Scholarship, Henniker Scholarship (1867), and three exhibitions. T. C. presents to eleven livings, and in 1878 had 90 undergraduates, 235 members of Convocation, and 404 members on the books.

Trin'ity Hall, Cam'bridge, was founded in 1350 by William Bateman, Bishop of Norwich, being specially designed for the study of law. Under the new Statutes of 1863, it is governed by a master (Sir H. J. Sumner Maine since 1877), and has thirteen foundation fellowships (ten of them lay), four law studentships of £50 for three years, sixteen other scholarships of from £70 to £21 per annum up to the B.A. and LL.B. degree, and two exhibitions of £70 for one year. T. H. presents to six livings, and in 1878 had 180 undergraduates, 156 members of the senate, and 528 members on the books.

Trin'ity House was established by charter of Henry VIII., in 1514, as a corporation of 'shipmen and mariners' of England, and was designed for the 'relief, increase, and augmentation of the shipping of the realm,' with powers to make laws and ordinances for that end, and out of their revenues to maintain almshouses at Deptford, and to relieve poor seamen—charities which exist to the present day. By an Act of Elizabeth the corporation was enabled to erect sea-marks; and from the powers under this statute the lighthouse system of Great Britain has been developed. One of the functions of the corporation has always been the regulation of pilots, in respect of which their powers were enlarged by charter of James II. in 1685, and by subsequent Acts of Parliament. Formerly the board had the sole right of ballastage on the river Thames. The board used also to have powers to examine masters and mates in the navy. The corporation (1879) consists of 24 members, including a master, deputy, wardens, and elder brethren, besides a number of younger brethren. Eleven of the 24 members are usually men of high position, while thirteen are experienced commanders of merchant ships. The master and deputy are chosen annually.

Trin'ity Sunday, the Sunday next after Whitsunday, is the Festival of the Holy Trinity. This festival formed the climax to the cycle of festivals commemorating the different events in the Life of Christ, as the doctrine of the Trinity was the culmination of the development of doctrine regarding his person. When the festival began to be observed is disputed; it was made general by a decree of Pope John XXII. (1316-1334).

Tri'o, a musical composition for three voices or instruments, or the second part of a minuet. The latter was originally written in three parts, or for three instruments in the orchestra.

Tripe de Roche, a name given by Canadian hunters to various species of lichens with a blistered thallus belonging to the *Umbilicariæ* tribe. The starch they contain (*Lichenine*) can be utilised either as a jelly or as flour. Unfortunately it is conjoined with a purgative and nauseous bitter principle (*cetrarine*).

Tripett'y, or **Tripatore',** a town in the district of N. Arcot, Madras Presidency, British India, on the right bank of the river Palar, 137 miles S.W. of Madras by rail. It is celebrated for the fine pagodas built on the neighbouring hills, to which pilgrims flock in thousands from all parts of India. As a shrine, it is only second to that of Juggernauth in Orissa; and the high priest is known to derive an immense income from votive offerings. T. has a special manufacture of brass work inlaid with copper. Pop. (1871) 10,423.

Trip'le Alli'ance. (1) The league concluded at the Hague in 1668 between England, Sweden, and the States-General for the protection of the Spanish Netherlands against Louis XIV. (2) The league concluded in 1717 between England, France, and the Netherlands against Spain, which guaranteed the Protestant succession in England. (3) The league concluded in 1795 between England, Russia, and Austria.

Trip'let, in music, a group of three notes played in the time of two, indicated by a slur and the figure 3.

Triple Time, in music, is a common measure of time, in which there are three beats to the bar. In compound T. T. there are six beats, the emphasis falling on the first and fourth.

Tri'pod (from Gr. *tripous*, 'three-footed'), any article of furniture resting upon three feet, more especially tables, caldrons, and bronze altars. The tripods used in the temples were frequently made of precious metals, and richly covered with ornaments. The T. was peculiarly connected with the worship of Apollo: upon it the Pythian priestess at Delphi sat, and it was a frequent prize in the Pythian games, as well as a common reward to a successful choragus at Athens.

Trip'oli, the most easterly of the Barbary States, and a regency of the Ottoman Empire, lies between Tunis and Egypt, and has an uncertain southern boundary. Exclusive of the territory of Barca (q. v.), which since 1869 has been made directly tributary to Constantinople, and of Fezzan (q. v.), which is really independent, the area of T. is about 140,000 sq. miles, and the pop. 1,150,000, in the towns mostly Moors, throughout the country mostly Beduins and Berbers. The country consists of a sandy plain bordering the sea, and from 50 to 100 miles broad, merging on the S. into the stony plain of Hammada, which is succeeded by three mountain-ranges having an elevation of 2800 feet, S. of which the land descends to Fezzan. There are no rivers or lakes, and rain falls but seldom, except on the coast or in the mountains. The climate in the hilly districts is healthy, though liable to extremes; but in the lowlands deadly fevers prevail. The country is generally bare and treeless, a foolish tax having been imposed on every fruit-tree planted, in spite of which, however, the cultivation of the date-palm, fig, olive, and orange is increasing. Wheat and barley of the finest quality, as well as cotton and senna, are extensively grown, but esparto grass is now the most important natural product. Horses of a small size but good breed, cattle, and sheep, are reared in large numbers. Formerly T. enjoyed a large transit trade with the Sahara and the states on its southern border, but this has greatly fallen off of late years, owing to the abolition of the slave trade and the competition of the Niger route. In ancient times T. was successively subject to the Cyrenæans, Carthaginians, and Romans. The last called it the *Regio Syrtica*, a designation which gave way in the 3d c. to that of *Regio Tripolitana* (whence the name T.), derived from its three chief cities, Œa, Leptis, and Sabrata. The Arabs succeeded the Romans, and in 1552 T. was conquered by the Turks, but it was practically an independent kingdom from 1714 to 1835, when the Turks forcibly re-established their authority. It is now ruled by a Pasha, and held by an army of occupation of only 4500 men. There is a good deal of fanaticism in the country, which is occasionally unpleasant for travellers. See Testa, *Notice Statistique et Commerciale sur la Régence de T.* (Haag. 1856), and Rae's *Country of the Moors* (Lond. 1877).

Trip'oli (Turk. *Tarabolûs*), capital of the African state of the same name, stands on a small rocky promontory on the Mediterranean, and probably occupies the site of the ancient Œa. It has twelve mosques, several synagogues, a Catholic chapel, and an indifferent harbour. Girt with high walls, it is irregularly built, and is famed for the beauty of its palm groves. It has steam communication with Malta, and is thus connected with the ports of Italy, France, and England thrice a month. In 1877 the value of its import trade was £300,500, and of its exports £400,700, the chief items of the latter being esparto, ostrich feathers, ivory, butter, and gold dust. T. has also important manufactures of leather, woollens, and silk goods. Pop. 27,000. T. is connected with Malta by a submarine telegraph cable.

Trip'oli (Turk. *Tarabulûs*), a town in the vilayet of Syria, at the foot of Lebanon, on the river Kadisha, 2 miles from its mouth. Its castle was built by Raymond of Toulouse during the first crusade, and seven remaining towers still in good preservation attest its former strength. Its port, El Myna ('the landing-place'), was entered (1876) by 1965 vessels of 135,930 tons, and the exports (grain, fruit, sponges, wool, oil, tobacco, and silk) amounted to £43,980, the imports to 9857. Pop. 25,000.

Trip'oli is a fine-grained siliceous deposit, crumbling easily, and valuable as a polishing material for metals, marble, glass, &c. It has a dry, harsh feel, and a gray or yellow colour. The silica present is derived from the casts of *diatoms*. The name is derived from its having been originally brought from T. in Africa, but deposits occur in Tertiary formations all over the globe.

Tripoliz'za (officially Tripolis, 'three cities'), a town of Greece, capital of the nomarchy of Arcadia in the Morea, 39

miles S.W. of Corinth. It stands on an elevated plain near the sites of the ancient towns Tegea, Mantinea, and Pallantion (hence its name). From 1718 to 1821 it was capital of the Morea, and its pop. reached 20,000. On the 17th October 1821 it was stormed and burned by the Greeks. Ibrahim Pasha retook it, 21st June 1825, but it was again surrendered in 1828. Though much of it has been rebuilt, the pop. now is only 7000.

Tripp'ant, or **Tripp'ing**, in heraldry, is applied to animals of the chase, to denote that they are in easy motion. A lion so moving is said to be *passant*.

Trip'tych (Gr. *tris*, 'thrice,' and *ptyssō*, 'I fold'), an altar-piece in three divisions. In early times altar-pieces seem to have been small and portable, in their oldest form consisting of two leaves or tablets of ivory or wood like the *diptychs* of Roman consuls. In later times the most frequent form came to be that of the T., with a large central division, on which was some sacred pictorial representation, while on the insides of the two wings were pictures corresponding to those on the central piece. When there were more than three divisions it was called a *polyptych*.

Tri'remes (Lat. 'with three banks of rowers'), the common galleys or ships of war among the Greeks and Romans, ordinarily manned by about 200 men, and propelled at great speed.

Trisag'ion (Gr.; Lat. *ter sanctus*, 'thrice holy'), or **Cheru'bic Hymn**, employed always in the mass and in the communion service, was in use in the Church as early as the 2d c. In its original form it was in the exact words of Isaiah vi. 3, with the addition of 'who art blessed for ever. Amen.' Additions were afterwards made, to express both orthodox and heretical points of faith, but most of these were rejected in the Western Church.

Trismegis'tus. See HERMES.

Tris'mus Nascen'tium, or tetanus of new-born children, is a malady which is now seldom met with in this country, except in certain localities where it appears to be endemic. T. N. is said to be common among negro children in the Southern States of America, and it has been and still is common in the island of St. Kilda. At Westmannö, a small islet off the coast of Iceland, 64 per cent. of the infants born die of it between the fifth and twelfth day from birth. Eighty years ago, every sixth child born in the Dublin Lying-in Hospital died within a fortnight after birth, and T. N. was the cause of the death of nineteen-twentieths of these children. Dr. Joseph Clark adopted means to secure the efficient ventilation of the hospital, and the mortality of the children fell at once to 1 in 19¼; and from 1826 to 1833 the mortality was only 1 in 58¼; and but little more than the ninth part of that mortality depended on T. N. The disease seems to depend, essentially, on defective hygienic conditions in the dwelling, dirt and defective ventilation being common to the inhabitants wherever the disease prevails. T. N. generally terminates fatally within thirty-six, often within twenty-four, hours from the appearance of the first symptoms.

Tris'tan, or **Tris'tram**, is the centre figure of a circle of old Celtic myths, which with countless modifications and additions afterwards appeared in all the chief European literatures. According to the story, T., son of Rouland Rise, Lord of Ermonie, and Blanche Fleur, sister of Mark, King of Cornwall, was sent by his uncle to woo vicariously and bring home as bride to the British king the fair Isolt, Yseult, or Ysonde, princess of Ireland. T. does so, but they unfortunately partake of a love charm which is not intended for them. They fall passionately but hopelessly in love with each other. The intrigue was carried on for years, and the story narrates the adventures—grave and gay—which resulted from the somewhat difficult position of the actors. They died simultaneously, and the king generously allowed them to be buried side by side. But 'even in our ashes live their wonted fires,' a vine and a rose-bush grew from the graves, and, meeting, twined amorously their branches together. The most important romance extant on the subject is that composed about 1170 by the Norman-English chevalier, Luce de Gast. The legend got abroad to France, and from thence mixed with the Arthurian myths to Germany, where Gottfried of Strassburg re-narrated part of the story in a lively but immoral poem (1210), which had great popularity in the Middle Ages. Hans Sachs is one among a host of old writers who have treated the subject. The Auchinleck MS. of *Sir Tristram* was published by Walter Scott in 1806. Dr. G. Brynjulfson, in his edition of the *Saga af T. ok Isönd samt Möttuls Saga* (Copenh. 1879): a version composed in 1226, and which appears to be a translation of the first form of the story, attempts to connect it with the Scotch *Sir Tristram*, and to show that Orkney was the point of transition between the North-French and Norman-English romances and Scandinavia. See Bossat, *Tristan et Iseult* (Par. 1865); Bechstein, *T. und Isolt in der Deutschen Dichtung der Neuzeit* (1877), and Kölbing, *Die Nordische und Die Englische Version der Tristansage* (Heilb. 1878).

Tris'tan da Cun'ha, a volcanic island in the S. Atlantic, situated in 37° 6′ S. lat., midway between S. America and the Cape of Good Hope. It was discovered in 1506 by the Portuguese navigator whose name it bears, and in 1816 was occupied by a detachment of British soldiers as an outpost of St. Helena, which is 1300 miles distant. The detachment was withdrawn after the death of Napoleon I. in 1821, but a corporal named Glass, and two sailors from a man-of-war at St. Helena, were allowed to settle on the island with their families. A few whaling men afterwards joined them, and in 1878 the pop. had risen to 97. The island, which is about 20 miles in circumference, rises precipitously from the sea on all sides, and has no safe anchorage. It consists chiefly of mountains from 2500 to 3000 feet in height, culminating in a peak 7640 feet high. Scrub and dwarf pine trees are plentiful, and there are tracts of good pasture and arable land, but cultivation is limited by the fierce winds which prevail, and by the ravages of mice. Cattle-rearing, fishing, and sealing are the chief occupations of the inhabitants, who obtain flour, clothing, tea, &c., from passing vessels, whalers, and men-of-war which occasionally call. The island is nominally under the jurisdiction of the Cape Government, and is included in the diocese of St. Helena. 20 miles distant is an islet called Inaccessible Island, on which two Germans lived an adventurous life in 1871–73, when they were taken off by H.M.S. *Challenger*.

Trit'icum. See WHEAT, and COUCH GRASS.

Tri'ton, a son of Poseidon and Amphitrite, dwelling in their palace in the depths of ocean. In works of art, where T. is frequently represented, he is usually a man above, a fish below, and rides erect over the waves carrying a conch or shell-trumpet, by blowing which he smoothes the sea when it is agitated. In later writers the word is often plural, and in later art numerous Tritons were represented.

Tri'ton, a genus of *Amphibia* vertebrates, including the water-newts of our ponds and ditches. The *T. aquaticus*, *T. cristatus*, *T. Bibronii*, and *T. marmoratus* are familiar species. See NEWT. The name is also given to a genus of Gasteropodous molluscs, of which the *T. variegatus* or Sea Trumpet, the *T. anus* or Wrinkled T., and the *T. distortus* or Twisted T., are examples.

Tri'umph (Lat. *triumphus*), a solemn procession in ancient Rome for the purpose of celebrating a victory. The *Imperator* who was thought worthy of the honour entered the city by the *Porta Triumphalis*, and proceeded in a car drawn by four horses along the *Via Sacra* to the Capitol, where he sacrificed a bull to Jupiter. He was preceded by the Senate and the magistrates, and followed by long files of his captives and of all his army. It was the occasion of a public holiday of the most joyous description, and was looked upon as the highest honour that could be bestowed upon a successful Imperator. Under the empire only the Emperor enjoyed a T., generals in the provinces being considered as his lieutenants. A lesser T. was the *Ovatio*, so called because a sheep was sacrificed instead of a bull. The chief difference was, that, in the latter, the general entered the city on foot, was not preceded by the senate, carried no sceptre, and wore a myrtle instead of a laurel wreath.

Trium'virate (Lat. *tres*, 'three,' and *vir*, 'a man'), the name applied in Roman history to two famous coalitions, the first in 59 B.C. between Cæsar, Pompeius, and Crassus; the second in 43 B.C. between Antonius, Octavianus, and Lepidus.

Trivan'drum, the capital of the native state of Travancore, in the extreme S. of the Indian peninsula, 50 miles N.W. of Cape Comorin, and 2 from the Malabar coast. In the centre is a large fort, which contains a celebrated pagoda, the royal palace, and the courts of law; about 2 miles distant is the Residency of the British Political Agent. There is an excellent high school, hospital, and observatory, all under European superin-

tendence. Among the inhabitants are many native Christians, mostly Roman Catholic, and also descendants of early Dutch and Portuguese settlers.

Triv'et, Nicholas, son of one of the King's Justices in eyre, was born about 1258, studied at Oxford and Paris, entered the Dominican order, and died in 1328. His chief work is a Latin chronicle on the six English Kings of the House of Anjou (1136–1307). It was first published in 1719 by Anthony Hall, and again in 1845 by Thomas Hog for the English Historical Society. T. has considerable merit as a historian. He is careful and trustworthy in his use of authorities, writes well, and breathes a religious spirit.

Triv'ium. See QUADRIVIUM.

Trocade'ro, a fort of Spain, province of Cadiz, 4 miles S.S.E. of Cadiz, captured by the French August 31, 1823. This victory has been commemorated in the name of the *place* in Paris opposite the Champs de Mars, and in that of the permanent building in connection with the Exhibition of 1878.

Tro'chidæ, a family of *Gasteropodous* Molluscs, included by some authorities in the family *Turbinidæ*. In the typical genus (*Trochus*) the shell has a flattened base, and is of pyramidal shape. The aperture is oblique and rhombic in form, and the *operculum* is of horny consistence. The T. are abundant on British coasts. The common Top (*Trochus zizyphinus*) is a familiar species, and the Nilotic Top (*T. Niloticus*) is another form belonging to this family.

Tro'chilus. See HUMMING-BIRD.

Tro'chu, Louis Jules, the defender of Paris against the Germans, was born at Le Palais, in Morbihan, May 12, 1815. In 1835 he entered the special military school at Paris, in 1840 became staff-lieutenant, and in 1841 accompanied the 6th Light Infantry to Algiers. In 1842 adjutant of Lamoricière, and in 1846 of Marshal Bugeaud, he became in the June of 1852 Director of the Staff in the Ministry of War at Paris. In the Crimean War he was adjutant of Marshal Saint-Arnaud, and, after his death, of General Canrobert; became in November 1854 General of Brigade, and at the head of the First Brigade of the First Army Corps covered himself with glory at the storming of the Malakoff, September 8, 1855. At the battle of Solferino in 1859 he led a division, and after the peace entered the war ministry, where he was destined as the successor of Niel. His pamphlet, *L'Armée Française* (1867, 20th ed. 1870), however, which revealed the weakness of the French army and advocated the adoption of the Prussian system, cost him the favour of the Emperor. On the outbreak of the German War he was summoned by Napoleon to the camp at Châlons, and appointed Governor of Paris, and on the popular revolution which followed the disaster at Sedan he became Commander-in-Chief of the army of defence in Paris. T., however, proved a man of plan more than of action, and on the 22d January 1871 he resigned his military command to General Vinoy, and in February his civil authority to the National Assembly of Bordeaux. In March 1872 he brought an action for libel against the editor of *Figaro*, in which he was unsuccessful, while his conduct since September 4, 1870, was subjected to much sharp criticism from the press, in consequence of which he resigned his place as a member of the National Assembly in July, and retired into private life at Belle Isle. He has since written several pamphlets defending his administration. See his *L'Empire et la Défense de Paris devant le Jury de la Seine* (1872). *Pour la Vérité et pour la Justice* (1873), and *La Politique et la Siége de Paris* (1874).

Trog'lodytes (Gr. *trōglodytai*, 'cave-dwellers,' from *trōglē*, 'a hole,' and *dyō*, 'I enter'), the Greek name for a savage Ethiopian people to the S. of Berenice, who dwelt in holes or caves—now a general term for people at a like stage of civilisation.

Trog'lodytes, a name applied in zoology (1) to a genus of *Dentirostral* birds, of which the common Wren (q. v.) (*T. vulgaris*) is the most familiar species; and (2) to a genus of *Anthropoid* apes, represented by two species, the Gorilla (*T. gorilla*) and the Chimpanzee (*T. niger*).

Tro'gon, the name given to a large family (*Trogonidæ*) of *Fissirostres* (q. v.). The bill is short, triangular, and broad at its base, which is furnished with bristles. The wings are of moderate size and rounded, and the tail is long. The tarsi are short and feathered. There are two toes in front and two behind. The *Trogonidæ* inhabit both the Old and New Worlds. Their plumage is, as a rule, brilliant in colour; carmine, green, and gold being the prevailing tints. The disposition of their mouth clearly indicates their insect-feeding tendencies. In the typical genus *T.* the bill has a highly-curved keel, and the nostrils are hidden by plumes. The wings have their fourth and fifth quills longest, and the two front toes are united to the first joint. Other genera included in the family are *Apaloderma*, *Priotelus*, *Harpactes*, and *Calurus*.

Troizk, a town of Russia, government of Orenburg, on the Welka, an affluent of the Ui, which joins the Tobol, 207 miles S.E. of Jekaterinburg. Its great bazaar is the scene of an active exchange trade with the Kirghese. Pop. (1875) 8298.

Troll'ope, Mrs. Frances Milton, an English novelist, the daughter of a clergyman, was born at Heckfield in 1779, and became in her nineteenth year the wife of Anthony T., a barrister-at-law, who died in 1825. During most of her married life she resided at Harrow, and in 1829 she went to America. The result of a three years' residence, her *Domestic Manners of the Americans* (1832; new ed. 1849), was with some justice condemned by our cousins as a caricature, but secured the reputation of the writer for keen observation, incisive criticism, and genuine if sometimes ungenial humour. Henceforth her life was devoted to ceaseless literary labour, and although already more than fifty years of age, she subsequently produced, besides several books of Continental travel, upwards of thirty novels. Many of these are now forgotten, but among others which have some chance at least of permanent popularity are *The Vicar of Wrexhill* (1837; new ed. 1860), *Tremordyn Cliff* (1838), *The Widow Barnaby* (1839), *The Widow Married* (1840), *The Barnabys in America* (1843), *Petticoat Government* (1852), and *The Clever Woman* (1854). During her later life Mrs. T. resided at Florence, where she died 6th October 1863.—**Thomas Adolphus T.**, eldest son of the preceding, was born 29th April 1810, and educated at Winchester and Oxford, and has resided in Italy since 1841. He is a prolific, scholarly *littérateur*. His works comprise *Catharine de Medici* (1856), *A Decade of Italian Women* (1859), *Paul V. the Pope and Paul the Friar* (1860), *La Beata*, a graceful story (1861), *Lindisfarn Chase*, a novel (1864), *History of Florence* (4 vols. 1865), *Durnton Abbey*, a novel (1871), *A Family Party in the Piazzi of St. Peter, &c.* (1877), and *Pius IX.* (2 vols. 1877).—**Anthony T.**, another son, born 24th April 1815, has added fresh lustre to the family name as a novelist. Educated at Winchester and Harrow, he was employed in the British postal service 1834–67, lived for several years in Ireland, and travelled extensively in America, Australia, and Cape Colony. He was an unsuccessful Liberal candidate for Beverley in 1869, and was for some years editor of *St. Paul's Magazine*. After issuing several Irish stories, he first attracted attention by *The Warden* (1855), the continuation of which, *Barchester Towers* (1857), remains one of his happiest efforts. These were followed by *The Three Clerks* (1857), *Doctor Thorne* (1858), *The Bertrams* (1859), *Castle Richmond* (1860), *Framley Parsonage* (1861), *Tales of all Countries* (1861; 2d series 1863), *Orley Farm* (1862), *Rachel Ray* (1863), *Small House at Allington* (1864), *Belton Estate* (1864), *Can You Forgive Her?* (1865), *The Claverings* (1867), *Last Chronicle of Barset* (1867), *Phineas Phin* (1868), *He Knew He was Right* (1869), *Sir Harry Hotspur* (1870), *Vicar of Bullhampton* (1870), *Ralph the Heir* (1871), *The Eustace Diamonds* (1873), *Phineas Redux* (1873), *The Way We Live Now* (1874), *The Prime Minister* (1875), and *The American Senator* (1877). Peculiarly the novelist of clerical life, T. is thoroughly English in feeling, and, though lacking depth and keenness, has a power of piquant characterisation, and a style that charms by its fluent grace. T.'s morality is not ideal, but it is genuine. His heroines in particular are models of grace, refinement, and purity; they breathe the sweet air of English homes, and throw an irresistible charm over even the conventional forms of English society. He is the author of several agreeable books of travel —*The West Indies and the Spanish Main* (1859), *North America* (1862), *Australia and New Zealand* (1873), and *South Africa* (2 vols. 1878).

Trom'bone, (1) a large musical wind-instrument, formed of brass, and composed of two separate parts or slides fitting into each other. By the manipulation of the slides the tube of air is altered in length, and the pitch accordingly varied. Trombones are

of three kinds, alto, tenor, and bass, with the following compasses:—

Two or three notes more may be produced, but they are difficult and uncertain, and these are the safe compasses. The T., when judiciously used, and when its tone is not forced, is a very effective instrument. Its sound is powerful, deep, and full. Glück seems to have been the first great composer who employed it in the orchestra. (2) A powerful reed organ-stop.

Tromp, Martin Harpertzoon, the greatest of the great Dutch admirals, was born at Briel in 1579. His grandfather was a coasting trader, and before he was nine years of age he was taken to sea by his father, whom he saw killed in an action with a Spanish ship in the following year, and whose death he lived to avenge. Captured in the same action, and forced to serve in the Spanish navy for nearly three years, he reappears as a lieutenant in the Dutch service in 1622, and has gained the command of a frigate by 1624. In 1637 he was advanced, as lieutenant-admiral, to the command of a squadron of eleven ships. Two years later he blockaded a powerful Spanish fleet under D'Oquendo in the Downs. An English fleet was sent to preserve neutrality, and its commander, Pennington, informed the belligerents that he was ordered to fight whichever fired the first shot. T. then invited D'Oquendo to come forth and fight, and the Spaniard replying that he had no powder, was offered half of the Dutch stock. The Spaniard remaining at anchor, T. attacked and defeated him, leaving a squadron to watch the English, who, however, were little inclined to spoil the sport. This victory, by which 40 ships were burned and 4000 prisoners taken, spread T.'s fame throughout Europe. He was ennobled by Louis XIII., and knighted by Charles I. in 1642. On 19th May 1652, an encounter in the Channel between T. and Blake, in which the latter was victor, preceded any declaration of war, but on 29th November following T. defeated Blake off Dungeness. After this action, tradition asserts that T. hoisted a broom at his masthead, to signify that he would sweep the English from the Channel. But the English soon again mustered, and under the united command of Monk, Deane, and Blake, engaged T. in a terrific conflict, which began off Portland, and after lasting three days (18th to 20th February 1653), ended with the retreat of the Dutch to Flushing. The English took or destroyed 11 war-ships and 30 merchantmen, killed 2000, and captured 1500 of the enemy. T. knew well the rough, daring, obstinate character of English sailors, and had vainly warned the Dutch, long accustomed to easy successes over the Spaniards, of the danger which his skill and courage were powerless to avert. Again, in 1653 (2d and 3d June), at the head of an undisciplined fleet, he was defeated off the North Foreland with fearful carnage, and the loss of 17 vessels. Monk, while cruising off the Dutch coast, had ordered captive vessels to be 'made short work of,' and on 7th August 1653 T. attacked him within sight of Scheveningen. Struck by a musket-ball, T. fell, while a furious fight was raging round the *Brederode*, which had so often borne his flag victorious. Thirty ships perished in this battle, and both sides claimed the victory. Ruyter (q. v.), who succeeded T. in the chief command, fought under him in all his English battles. T.'s monument at Delft, where he is buried, tells how 'he left to posterity a grand example of mastery in naval warfare, of fidelity to the state, of prudence, of courage, of intrepidity, and of immovable firmness.'—**Cornelius van T.**, son of the preceding, born 1629, fought under Ruyter (11th to 15th June 1666) in the great sea-fight against the English off the Downs, in three battles (7th and 14th June and 21st August 1667) prevented the Anglo-French fleet from landing in Holland, served for Denmark 1676-78, and, just as he was about to take command of the Anglo-Dutch fleet against the French, died at Amsterdam, 29th May 1691. See J. de Liefde's *Great Dutch Admirals* (Lond. 1873).

Trom'sö, a town of Norway, capital of the *amt* of the same name, beautifully situated on the island of T. (5 miles long, between Qvalö and the mainland), 131 miles S.W of Hammerfest. T. has several churches (one Catholic), a 'Latinskole,' a teachers' college, and a museum. It carries on a productive seal and herring (100,000 barrels in 1876) fishery, and exports fish and train-oil to Russia, Germany, and the Mediterranean to the value of £100,000 a year. Founded in 1794, T. had in 1816 a pop. of 300; in 1876, 5454.

Tron Weight, the most ancient system of weights used in Scotland, and though not now legal still lingers in certain rural districts. The tron pound was not well defined in value, but varied from 21 to 28 ounces avoirdupois. The name is derived from the Fr. *trone*, 'a beam' set up in the market-place to weigh heavy commodities.

Troon (Cymric Celt. *trwyn*, a 'promontory'), an important seaport in the county of Ayr, Scotland, 10 miles S.W. of Kilmarnock, and 6 N. of Ayr by rail. Pop. (1871) 2790. T. has a fine harbour, with wet and dry docks, and exports coal and iron. The average shipments for the years 1874-78 were 508,423 tons. Occupying a bare, level spit of land, the sea-winds sweep freshly over the place, and give it the most bracing atmosphere on the Clyde. It is in consequence a favourite resort of summer visitors. Both on its N. and S. shores T. has a splendid stretch of sands, unrivalled in the W. of Scotland. In 1878 part of the links (here known as 'knowes') was laid off as a golfing-ground, and a golf club started. In the neighbourhood is Fullarton House, a fine mansion belonging to the Duke of Portland, with the quaint old church and churchyard of Crosbie close by; and some 3 miles inland from T., on a grassy knoll, stands the historic ruin of Dundonald Castle, in which Robert II., the first of the Stewart kings, died. See the Rev. John Kirkwood's *Troon and Dundonald* (Kilmarnock, 2d ed. 1876).

Troop (Fr. *troupe*, prob. connected with Lat. *turba*, 'a crowd'), a body of cavalry corresponding to but smaller than a company of infantry. Two troops, usually of sixty men each, go to a squadron and eight to a regiment of cavalry.

Troop'ial (*Molothrus*), a genus of *Conirostral* birds, of which the Cow T. (*M. pecoris*) found in N. America, and deriving its name from its habit of associating itself with cattle, is the most familiar species. The head and neck are drab-coloured, and the general colour is a black glossed with green, the upper part of the breast being dark violet. The average length of the Cow T. is about 7 inches. The bird deposits its eggs within the nests of other birds, and thus resembles the cuckoo; the foster-parents attending to the young troopials almost (it is said) in preference to their own brood. The names 'Cow Bird,' 'Cowpen Bird,' and 'Cow Blackbird' are also applied to the T. Another species, the *Dolichonyx oryzivora*, or Bob-o'-Link, also named the Rice T., is a familiar American bird, noted for its devastations on rice-fields.

Tropæ'olum, a genus belonging to *Geraniaceæ*, consisting of about forty species all natives of S. America (two or three extending perhaps to Mexico, and almost confined to the mountainous region on the western side extending from New Granada to Chili. Their hardiness in a temperature above freezing point, combined with singular blending of colours in the flowers, and the diversity of foliage they present, place the genus among familiar and appreciated garden plants. *T. minus* and *T. majus*, introduced into Europe soon after the discovery of America, are the parents of many of the ornamental hybrids now common. The herbage and flowers serve as a salad, and the flower-buds and young fruits make a piquant pickle as a substitute for capers. A powerful acrid volatile oil can be distilled from the plants. The Canary Creeper (*T. aduncum* or *peregrinum*) fully merits its pre-eminence as a garden favourite; its native home is the Andean region, and it was introduced into England in 1775. The beautiful *T. tuberosum* is cultivated in Peru for its tubers, which are an article of daily food. *T. speciosum*, a magnificent species with gorgeous crimson-red flowers, festoons shrubs and small trees in Chili with slender stems 15-20 feet long. One species (*T. azureum*) has blue flowers. The names Nasturtium and Indian-cress applied to the common T. were given at an early date from the coincidence of properties with the ordinary cress and the water-cress, and not from any botanical affinity.

Trope (Gr. *tropē*, from *trepō*, 'I turn'), in rhetoric, a term applied to a word or expression diverted from its original to a figurative signification, and thus including Allegory (q. v.), Irony (q.v.), Metaphor (q. v.), Metonymy (q. v.), Synecdoche (q. v.), &c.

Tropho'nius, the fabled builder of the temple of Delphi, after his death was reverenced as a hero, and had a famous oracle in a cavern near Lebadeia in Bœotia. Pausanias describes (ix. 39) how, after purifying himself, he was drawn through the mouth of this cave by an unseen power, and all that he witnessed there. Don Quixote's fancied visit to the oracle preserves its memory.

Tro'phy (Lat. *tropæum*, Gr. *tropaion*, lit., a memorial of the 'turning' or flight of the enemy), among the ancient Greeks, a monument raised on the scene of a battle to commemorate a victory, consisting of some of the arms, shields, and helmets of the defeated army affixed to the trunk of a tree or to a stone pillar. If a naval victory, it was erected on the nearest land. Trophies were usually dedicated to some divinity, and it was considered sacrilegious to demolish them; but when they became decayed through time, it was not customary to repair them. The Romans generally ornamented the buildings of the city with the spoils of the vanquished.

Trop'ic Bird (*Phæthon æthereus*), a *Natatorial* bird belonging to the Pelican family (*Pelecanidæ*), and deriving its name from the fact that it is rarely seen outside the tropical circle. The T. B. breeds in Mauritius. The colour is white, marked on the back with black. The two middle feathers of the tail are extremely long. The average length is about 2½ feet, inclusive of the tail. The wings are long, and the flight extremely powerful. The voice is merely a shrill note. An allied species is the Roseate T. B. (*P. phœnicurus*).

Trop'ics (Gr. the 'turning-points' or limits), in astronomy, are the parallels of declination between which the sun's annual path in the heavens is contained. The one N. of the equator is called the Tropic of Cancer, the southern one that of Capricorn. The distance of each from the equator is equal to the sun's greatest declination, and is subject to a slight periodic variation. The zone upon the earth's surface which is included between the parallels of latitude corresponding to the T., is itself known as the T., or more correctly the tropical zone.

Tropp'au, the chief town of Austrian Silesia, lies on the Oppa, 106 miles S.S.E. of Breslau by rail. It is surrounded by fine gardens, replacing the old walls and intrenchments, and has three suburbs, six churches (one Evangelical), an old town-hall (lately rebuilt in Gothic style), a large barrack, a higher gymnasium and Realschule, a teachers' training college, a commercial school, and several benevolent institutions. T. manufactures cloth (chiefly military), machinery, beet-sugar, beer, potash, soda-water, lucifers, spirits, liqueurs, and paper. Pop. (1870) 16,608. T. was founded in the 13th c. From the 20th October to the 20th December 1820 a Congress, afterwards transferred to Laibach (q. v.), met at T.

Tross'achs (Gael. 'bristled territory'), a romantic defile forming an approach to the W. Highlands of Scotland, is situated in Perthshire, some 8 miles W. of Callander, and extends for about a mile between Lochs Achray and Katrine (q. v.). The pass, which winds between Ben A'an on the N. and Ben Venue on the S., is confined by lofty rugged precipices, feathered to their summits with birch, pine, and other trees; in the words of Scott, whose name will be associated for ever with the district—

> 'Crags, knolls, and mounds, confusedly hurl'd,
> The fragments of an earlier world.'

Troub'adours and Trouvères', the poets of Provence and Northern France, so called, according to Diez, as the *inventors* of lyric and narrative poetry (Pr. *trobar*; Fr. *trouver*, 'to find,' from Lat. *turbare*, 'to turn topsy-turvy'). M. Paris, however, in *Romania* (July 1878), suggests *tropare* (from *tropus*, 'song') as the true etymon, '*turbare* presenting phonetic difficulties, and failing to explain the meaning.' See PROVENÇAL and FRENCH LANGUAGE AND LITERATURE.

Trous-de-Loup (Fr.), in military operations, are rows of inverted conical pits, each with a pointed stake inside. They are a formidable obstacle to the advance of cavalry.

Trout, a term applied generally to various species of fishes belonging to the salmon family (*Salmonidæ*). Of the T. the best-known species, and that which *par excellence* receives the name, is the *Salmo fario* or Common T., a fish which inhabits clear and running streams, and is mostly to be found tenanting some special nook from which it has to be warily drawn by the fly of the angler. The colour of the T. is very characteristic. It is of a yellowish-brown colour above, variegated with a dark reddish-brown hue, and marked by spots of a brilliant carmine along the lateral line. Below, a silvery white lustre prevails, and the under part of the sides are a rich golden-yellow. The T. subsists largely upon insects, worms, and the like fare. The bait which tempts it varies greatly from the fly to the minnow. A very peculiar and at the same time interesting fashion of capturing T. is in vogue amongst juvenile fishers, and is named 'tickling.' This process consists in feeling beneath the river banks for these fishes, in holes and like situations where they rest; when a fish is touched, the hand is outspread to prevent its escape, while, apparently, the fish, mesmerised by the action of the fingers on its sides, remains sufficiently quiet to permit of its sudden and speedy capture. The colour and flesh of the T. appear to vary with the particular locality in which the fish is found. The average weight of the common T. is from ¾ lb. to 1 lb. Fishes which exceed 1 lb. in weight may be regarded as exceptionally fine specimens. The T. is found in all the large streams and lakes of Britain and of N. Europe at large. A second species of T. is the Salmon T. (*Salmo trutta*), which closely resembles the salmon in its general habits, especially in those relating to migration to the sea, and returning to the rivers to spawn. The Common T. spawns about the end of October, the sexual differences between male and female then becoming markedly apparent in the elongation of the lower jaw of the former; the Salmon T. spawning at about the same period. Certain species of T. are confined to certain lakes or streams, and are not found outside the bounds of these waters. In such cases special markings indicate the specific character of the fishes. Of such cases, a well-known example is the Loch Leven T. (*S. Levenensis*), which inhabits Loch Leven in Kinross-shire, a lake also tenanted by the common T. From the latter the Loch Leven T. is distinguished by its larger size, and by the more pointed form of the pectoral fins. The tail-fin is also more pointed than in the common T., and the flesh is reddish, and wants the white or pink tint of the Common Trout's muscles. The *pyloric cæca*, or blind and pocket-like appendages attached to the hinder margin of the stomach of most fishes (and supposed to represent a *pancreas* or sweetbread), number from 60 to 80 in the Loch Leven T., whereas in the Common T. they are much fewer. A third species of T. is the Great Lake T. (*S. ferox*), common in some of the larger lakes of Britain and Ireland. It may attain a weight of 30 lbs. or more, and has a prominent muzzle, and a square, truncated tail-fin. The colour is a dark brown, tinted with purple. This fish is a greedy feeder, devouring large numbers of smaller fishes, and is taken by night-lines, or by trolling with strong tackle and a small trout for bait. The flesh is coarser than that of the preceding species. Like the Loch Leven T., the Gillaroo T. is limited in its distribution to Lough Neagh and other lakes in the N. of Ireland; and the Lake T. (*S. Lemanus*) is confined to the Lake of Geneva.

In the New World trout are plentifully found. The common Brook T. (*Salmo fontinalis*) is almost identical, if not wholly so, with the Common T. of the Old World. A second well-known American species is the *Salmo confinis*, or N. American Lake T., which appears to find a congenial habitat in deep lakes. Its colour is dark, mottled with grey spots, and it may attain a weight of over 50 lbs. The Red-bellied T. (*S. erythogaster*) occurs in fresh waters in Pennsylvania and New York states, and averages from 1½ to 2 feet in length. The Oregon T. (*S. Oregonensis*) is one of the best-known and localised American species of T., inhabiting the rivers and streams which run from the Rocky Mountains, and resembling the Common T. of Europe both in size and appearance.

Law regarding T.-fishing.—The right of T.-fishing is conveyed along with the lands. No one standing on a highway, or on public ground contiguous to a stream, has a right to angle the stream, which is the property of those through whose ground it flows. (See RIVERS, LAW REGARDING.) In Scotland, where the right of salmon-fishing does not necessarily belong to the riparian proprietor, where one person has a right to the salmon-fishing and another has a right to the T.-fishing, the latter right must be exercised so as not to be injurious to the former.

Tro'ver, in English law, is an action to compel some one having wrongful possession of goods to restore them to the lawful owner. If the goods have been sold or exchanged for others, the plaintiff, if successful, will have pecuniary damage awarded to him.

Trow'bridge, a market-town of Wiltshire, England, on the Biss, 11¾ miles S.S.W. of Chippenham by rail. The 14th c. parish church (restored at a cost of £8000) contains the grave of the poet Crabbe, and other buildings are the market-house, court-hall, &c. T. is a growing place, with thriving manufactures of broad-cloths, tweeds, and kerseymere. It publishes two weekly newspapers. Pop. (1871) 11,508.

Troy (Gr. *Ilion*), the city of Priam, whose ten years' siege by the Greeks is immortalised in the *Iliad*, according to Homer, was capital of the Troad, a coast-region of N.W. Mysia, which, watered by the Scamander and Simois, and traversed by Ida and its spurs, stretched from Cape Lectum on the Ægean to Dardanus and Abydus on the Hellespont. Those modern writers who look on the *Iliad* as a solar myth have relegated T. to cloud-land; those, on the other hand, who discover an historic substratum in the Homeric poem, have hotly contested the city's precise locality. A few have placed it, with Strabo (xiii. 1, 35), at a 'village of the Ilians' (mod. Aktchi-kôi); and others, with the French traveller Le Chevallier (1786), on a height known as Bali Dagh, a mile beyond the Turkish village of Bunarbashi, and 10 miles from the Scamander's mouth. Against both, Grote upheld the traditional site, the hill of Hissarlik, 2 miles from the Hellespont, on which a town, preserving the name of Ilium, and visited as the 'Pergamus of Priam' by Xerxes and Alexander, was founded somewhere between 720 and 550 B.C. And Grote's opinion has been in great measure verified by the excavations of Dr. Schliemann, in 1871–73 and 1878–79, who had confirmed in 1867 the results of Von Hahn's researches (1864) at Bali Dagh, that its limited plateau could never have accommodated more than 2000 inhabitants, and that the small accumulation of soil or debris proved it to have been occupied from no very early date. At Hissarlik, on the contrary, he passed through five successive strata, the first or uppermost containing Greek coins and pottery, a beautiful statue of Apollo, and other Hellenic remains; the second a few bronze implements and fragments of charred wood; the third, at a depth of 13 feet, stone spear-heads, axes, and other implements of the so-called 'Stone Age;' the fourth (33 feet), fine pottery and bronze weapons and utensils; the last (52 feet), stone and bronze weapons intermixed. It is to the fourth stratum that Schliemann refers his later discoveries of a 'steel' dagger, the 'great tower of Ilium' (40 feet thick and 20 high), the triple 'Scæan Gates,' the 'palace of Priam himself,' and the wonderful gold 'treasure of Priam'—objects that, however doubtfully we receive their finder's enthusiastic identifications, have a high archæological value, and prove by their marks of the action of fire the former existence of a city that perished by conflagration. Schliemann himself, however, has had to own that if this were 'wind-blown T.,' we must cease to put faith in the Homeric details, since Hissarlik nowhere rises much over 100 feet above the plain, and its scanty area (335 by 135 yards) could never have held 50,000 inhabitants. See Grote's *Hist. of Greece* (vol. i., ch. xv.), and Schliemann's *Trojanische Alterthumer* (Leip. 1874; Eng. trans. 1875).

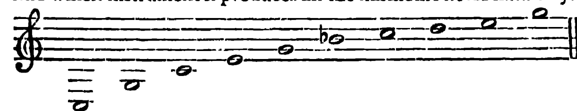
Troy, a town in the state of New York, U.S., on the Hudson river, 6 miles N. of Albany by rail. Two steam ferries and a new iron bridge (constructed at a cost of $250,000) connect it with West T. (q. v.) on the opposite bank. It contains 49 churches, a fine masonic temple, the Rensselaer Polytechnic Institute (1824), with 13 instructors and 190 students in 1875, a music hall (recently erected at a cost of $500,000), and numerous hospitals and educational seminaries. Three daily newspapers are published. There are important Bessemer-steel (the oldest in America) and other iron works, large bell-foundries and cotton factories. In 1876 the valuation amounted to $15,539,700, the debt to $846,144, and the annual tax to $532,146. Pop. (1876) 50,805.

Troyes, the chief town of the department of Aube, France, and the old capital of Champagne, in a wide plain on the left bank of the Seine, 103 miles E.S.E. of Paris by rail. The seat of a bishop, its cathedral of St. Pierre, a splendid flamboyant structure, was begun in 1208, but not completed till the 16th c. Other fine buildings are the collegiate church of St. Urbain of the 13th c.; the flamboyant St. Madeleine (1506), St. Nicolas, and St. Pantaleon, rebuilt after the great fire of 1524; the Hôtel-de-Ville of the 17th c., with fine façade; the once famous abbey of St. Loup, now a library containing 100,000 vols. and 5000 MSS., and the Hôtel-Dieu of the 18th c. T. has also a museum, theatre, exchange, celebrated battoirs, &c., and manufactures of woollens, cottons, gloves, hosiery, candles, soap, Spanish white, parchment, paper, brandy, &c. It carries on a large trade in wine, grain, and vegetables. Pop. (1876) 41,275. The capital of the Celtic Tricassi, T. was first called by the Romans *Augustobona*, but later *Tricassio* and *Tricassæ*, and since the 5th c. *Trecæ*, hence its present name. T. was the birthplace of Urban IV., and the place where was concluded between England and France the treaty of 21st May 1420. It was the headquarters of the Austrian army of invasion in 1814, and was taken by the Germans, under Prince Friedrich Karl, November 10, 1870. See Boutiot's *Histoire de T. et de la Champagne Méridionale* (Troyes 1873).

Troy Weight, a system of weights used in Great Britain for gold, silver, platinum, and precious stones. The Troy pound contains 12 ounces, 240 pennyweights, and 5760 grains, being thus less than the avoirdupois pound, which contains 7000 grains. The old apothecary's weight, which had the same value of pound as the Troy, but subdivided into 12 ounces, 96 drachms, and 288 scruples, was abolished by the Weights and Measures Act of 1878, and the new apothecary's weight made the same as the avoirdupois. The name Troy was given to the standard pound in 1495. The origin of the name is doubtful, some deriving it from *Troy Novant*, the monkish name of London, others from Troyes in France.

Truce, a suspension of hostilities between two nations or armies for a definite period, during which neither is at liberty to do anything to benefit itself at the expense of the other. The word T. contains the same root as *truth*, and implies that the agreement is meant to be honestly kept.

Truce of God. See GOD'S TRUCE.



Truck System (Fr. *troquer*, 'to barter;' hence Lowl. Sc. *trog*). This name is applied to a practice, formerly widely extended in Great Britain, of paying workmen in goods in lieu of money. Employers established stores at which the workmen were supplied with food, clothing, &c., to the value of their labour; or if money was paid as wages, they were compelled to purchase at these stores. Such an arrangement afforded opportunities to any unscrupulous master of taking mean advantage of his workmen, and as a rule this was regularly done, trashy and shortweighted goods being priced exorbitantly. The whole system was demoralising and corrupt. Among other evils it induced habits of improvidence and intemperance among the men. The T. S. was abolished in 1831 by the Truck Act, which provided that payment of wages was to be made only 'in the current coin of the realm.' The Act, however, continued to be systematically evaded. An investigation, conducted in 1854 at the instance of Parliament by Mr. Tremenheere in England and Wales, and by Mr. Hill Burton in Scotland, clearly proved this; and again the evidence taken in 1870 by a Truck Commission appointed by Act of Parliament, showed that while direct violation of the Truck Act was rare, kindred abuses were widely prevalent. The evils were supported by the 'long-pay' system, *i.e.*, the practice, which was general, of paying wages once a fortnight or once a month. During the interim few workmen with families could do without cash or its equivalent; part of their earnings were accordingly sought in advance of pay-day, and the sums advanced were expected to be expended at stores carried on for the benefit of the employers who paid the wages. In the mining and manufacturing districts of Scotland, 'poundage' to the extent of one penny per shilling or one shilling per pound was deducted from advances, and if a workman 'sloped the store' his advance-book was 'stegged,' so that the next time he applied for an advance it was refused. Continual shunning the store eventually led to the discharge of the offender from the mine or factory. Truck by evasion flourished in the coal and iron trades of S. Wales, and in Shetland it was reported that of a population of 30,000 two-thirds were 'trucked,' while the remainder were engaged in 'trucking.' The Truck Commission recommended that a 'short-pay' system be made imperative, but Government did not con-

sider it advisable to legislate further on the matter. It was said that the publication of the Commissioners' report had been the means of suppressing the abuses to a large extent, and that with energy and combination on the part of the workmen the T. S. in all its branches could be extirpated.

Truf'fle (*Tuber*), of the natural order *Tuberacei*, is a genus of Fungi growing under ground. Several species are collected as an aromatic flavouring agent for culinary purposes. The English T. is principally *T. æstivum*, of ovoid form, 2 to 3 inches long, black and warted externally, with a marbled flesh when cut across. It is met with in woods (often beech) on a calcareous soil, and for searching it a particular breed of dog is employed, the mode of discovery being by smell. In continental Europe sows are trained for a like purpose. The best French T. is *T. melanosporum*, with an exquisite strawberry-like flavour. Piedmontese T. (*T. magnatum*) is smooth outside and pinky-white within; it has a garlic flavour, and is much esteemed. *T. cibarium*, the black T. of middle and S. Europe, attains a weight of over a pound: either roasted or as a condiment it forms an aromatic food. *T. rufum*, found frequently in vineyards, is much used for food. To the genus *Chairomyces* the white T. (*C. meandriformis*) belongs. It grows to a large size, but is of an inferior quality, and is rare in England. The Australian T., called 'native bread,' is *Mylitta Australis*, a genus of uncertain affinities. This fungus sometimes attains the size of a cocoanut, is a fair esculent, and eaten by the natives. See Planchon, *La Truffe* (Par. 1875).

Trum'bull, John, an American painter, son of the governor of Connecticut, was born at Lebanon, in that state, 6th June 1756, graduated at Harvard in 1773, and served in the army for four years, for some time as Washington's aide-de-camp. In 1780 he passed to Paris to study art, and thence to West's studio in London, where, during the excitement caused by André's execution, he was seized as a spy and imprisoned for eight months. His after life was spent partly in England, partly in America, principally engaged with his art, but occasionally occupied in the diplomatic service of his country. After being for many years president of the American Academy, he died at New York, 10th November 1843. His early works, 'Bunker Hill,' 'Death of Montgomery before Quebec,' and 'Sortie from Gibraltar,' are greatly superior to his ambitious efforts in the Capitol at Washington; and of the decline in his art he was himself conscious, for he relinquished original work and disposed of his collection to Yale College for an annuity of $1000. T.'s pictures show dramatic feeling, vigorously rendered, but are mainly valuable for the faithful portraits they contain—among others, that of Washington.

Trump'et (Ital. *tromba*), a musical wind-instrument with a ringing and clear tone. It is formed of a single curved tube of brass or silver, and is fitted with a mouthpiece at one end and a bell at the other. The pitch is an octave higher than the horn, like which instrument it produces all the harmonic notes naturally.

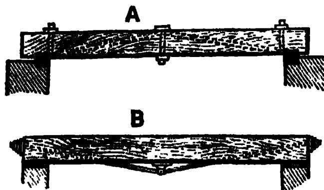
But by means of artificial contrivances, keys, &c., the others are obtainable. For power the open notes must be relied on. Its natural key is C, though by means of crooks and lengthening pieces the sounds produced may be of any key, and there are consequently trumpets in all keys. High trumpets are called clarini. Latterly it has become common in orchestras to use the cornet-a-piston in place of the T., but no pistoned instrument possesses the true T. tone. The T. was called into great requisition by Handel.

Trump'eter, a soldier in a cavalry or artillery regiment whose duty it is to sound on the trumpet the various regimental calls and signals.

Trump'eter (*Psophia*), a genus of *Grallatoria!* or Wading Birds inhabiting S. America, and represented by the *P. crepitans* or Golden-breasted T. and other species. It is so named from the deep, hollow sound it emits. The T. is readily tamed, and becomes a household favourite. The head and neck are glossy black, the back is grey, and the wings and under parts black. The feathers of the back are long and silky. The body is relatively small when compared with the legs. The bill is vaulted towards the tip, which overhangs the lower jaw. The fourth, fifth, and sixth quills are the longest, and the tail and hinder toe are short.

Trump'eter-Fish, or **Sea-Snipe**. See BELLOWS-FISH.

Trumpet, Sea (*Triton variegatus*), a species of Gasteropodous shells, also named the Conch Shell, attaining the length of a foot, and common in the South Seas, where it is used by the natives as a trumpet. The S. T. is of a white colour, streaked with brown and yellow. The outer lip is large and ribbed.



Trumpet-Flower, a name popularly applied to large tubular flowers, such as those of various species of *Bignonia*, *Tecoma*, *Catalpa*, *Solandra*, &c. The natural order *Bignoniaceæ* (q. v.) is called the T.-F. family; and *Bignonia* or *Tecoma radicans* as also the handsome *B. capreolata* are the T.-F. of the United States.

Tru'ro, a city of Cornwall, 53¾ miles W.S.W. of Plymouth by rail, stands at the head of a tidal creek formed by the confluence of the Allen and Kenwyn. In April 1878 it was resolved to replace the dilapidated St. Mary's Church (1518–1769) by a cathedral, subscriptions for which amount (April 1879) to £30,000, £20,000 more being needed. The new edifice, designed in Early Pointed style by Mr. J. L. Pearson, A.R.A., will be 250 feet long by 75 feet wide. Other buildings are three modern churches; the town-hall and market-house (1847), a granite Italian edifice, with the Stannary Courts in its rear; the public rooms (1868), in Tudor style, comprising the County and Bishop Phillpotts' libraries, a masonic hall, and a free assembly-room; the grammar-school; and the Royal Cornwall Infirmary (1779). As centre of a great mining district, T. carries on a considerable trade, its exports amounting (1877) to £6617 (£37,715 in 1873), customs to £7576, and imports to £156,774. There entered (1878) 759 vessels of 72,330 tons, and cleared 807 of 74,485; and on December 31 of the same year 56 vessels and 80 fishing-boats were registered as belonging to the port. Mining, shipbuilding (27 vessels of 2291 tons in 1874–78), and fishing (employing 132 hands in 1878) are the chief industries of T., which publishes three newspapers and returns two members to Parliament. Pop. (1871) 11,049. T., which emerged in history about 1175 as *Triueru* (Corn. 'three ways'), was one of the 'cordage towns' in 1305; gave birth to Samuel Foote, the brothers Lander, and Dr. Wolcot ('Peter Pindar'); and in 1877 was selected as the seat of the revived Cornish bishopric. See W. H. Tregellas, *Cornwall* (Lond. 1878).

Truss, an instrument used in the treatment of Hernia (q. v.) with the view of preventing its descent. A *single* T. is a spring surrounding the abdomen, above the spines of the ilia, terminating at one end in a pad, and at the other in a strap with button-holes. On the back of the pad there is a button to which the strap is secured, and the T. is prevented from displacement upwards by a strap, looped on its back part, brought under the thigh, and also buttoned on the pad. The T. may be adapted to either side, as required; and when there is a hernia on both sides, the spring has a pad at each end, and they are kept in position by a strap passing from one to the other. In the *spiral-spring* T. the pad has a spiral spring coiled in it, and the body-spring does not encircle the pelvis, but terminates in a larger pad on the loins, in which also a spiral spring is coiled, and which is attached to the pad by a strap passing round the sound side of the body. The *ball-and-socket* T. has the pad mounted on a ball-and-socket or universal joint, and in the single form the spring encircles the sound side of the body, crossing in front of the pubes, so as to direct the pressure of the pad up the inguinal canal. The *moc-main lever* T. derives its name from the pith of the silk-cotton tree, of which its pad is formed. A soft belt encircles the body, and to this the pad is attached, carrying a horizontal lever-spring which passes across to the opposite end of the belt. A good T. should fit accurately into the hollow between the buttocks and loins, and should be so closely applied to the hips as not to shift in the movements of the patient's body; but it should not be so tight as to gall the skin, nor should the end of the spring project against the wall of the belly.

Truss, in carpentry, an assemblage of timbers framed together and possessing perfect rigidity: one of the principal supports of a Roof (q. v.). The principle of the T. has been widely adopted in bridge-building. A Console (q. v.) is also called a T.

Truss'ing, a method of strengthening a wooden beam against sagging or deflection by placing within it a truss of iron or oak. A (see fig.) represents a 'truss-beam' with *cast-iron* rods inserted, and B another having *wrought-iron* tension rods not wholly enclosed in the beam.

Truss-Beams.

Trust, in the law of England and of Scotland, is a confidence affecting real or personal estate, reposed by some one in another. He in whom the confidence is placed is called the *trustee*, and he in whose favour the T. exists is called *Cestui Que Trust* (q. v.), or, in Scotland, the *beneficiary*. Trustees are accountable for the interest which they make, or might make, from the employment of money in their possession. The office of T. under a will or marriage-contract is purely honorary. Trustees for behoof of creditors are paid according to their trouble and to the magnitude of their transactions. 10 and 11 Vict. cap. 96 provides means for securing T.-moneys, and for relieving trustees from the responsibility of administering T.-funds when they wish to be so relieved. A trustee may not invest on personal security, or in stock of a private company, unless he is authorised to do so by the T.-deed. By Lord St. Leonards' Act, trustees and executors are authorised, unless forbidden in the T.-deed, to invest in the stock of the Bank of England, or in that of the Bank of Ireland, or on real security in any part of the United Kingdom; and in any security the interest of which is guaranteed by Parliament, and in consolidated stock issued by the Metropolitan Board of Works. If empowered by the T.-deed, trustees may lend on personal security; but joint-trustees may not lend to one of themselves, nor may they lend the T.-funds to accommodate any one; nor, unless authorised to do so, may they invest in any foreign fund. By the Debenture Stock (1871) Act, when a trustee is empowered to invest in the mortgages of a railway, or other specified kind of company, he may, unless forbidden under the T.-deed, invest in the debenture stock of such company. When a trustee is in doubt as to his duty, he should ask the sanction of a court of law before acting. He will be allowed full costs, but not the costs of an appeal. A trustee requires to act with great caution, and he must do nothing in his office by which any kind of profit will accrue to himself. A trustee for an estate of land had better not shoot over it, nor fish in its streams. A trustee retaining T.-funds in his possession may be liable to penal interest, and possibly to interest with annual rests. The essential principles of the laws of England and of Scotland with regard to T. are the same.

Trustee'. See TRUST.

Truxill'o, or **Trujill'o**, a town in the N. of Peru, 9 miles from the port of Huancacho. Except Lima, it is the only walled town in Peru, and it is well built and laid out, though decayed. Founded in 1535 by Pizarro, who named it after his native town, T. was under the Spanish viceroys a place of the greatest importance. Pop. 15,000.

Truxill'o, or **Trujillo**, in the province of Caceres, Spain, 60 miles N.E. of Badajos, is a picturesque but decaying town, noted as the birthplace of Pizarro. Pop. 5000. The ancient *Trogilium*, or *Turris Julia*, T. was held by the Arabs from 711 to 1185, when it was taken by Alphonso of Castille.

Try'gon. See STING-RAY.

Try'-sail, a fore-and-aft sail, with a boom and gaff, on a small mast abaft the lower mast of a ship.

Tsar'skoe Se'lo ('imperial town'), a town of Russia, province of St. Petersburg, 18 miles S. of the capital by rail. It contains eight churches and two palaces, the principal summer residences of the imperial family. The larger of these, built by Elizabeth in 1744, and embellished at great expense by Catherine II., is a noble building, though overladen with false ornament. It has a frontage of 782 feet, and contains a ball-room 141 feet long and 50 feet broad. In one of its wings is a marble gallery 270 feet long by 26 wide, with a noble Ionic colonnade adorned with bronze busts of the most famous men of antiquity. The great park, one of the most carefully planted in Europe, contains a Turkish kiosk, a Chinese hamlet with a pagoda, a bridge built of Siberian marble over a canal connecting two lakes, a marble statue of Count Orlof, and the artificial ruins of a Gothic castle, in the chapel of which stands the marble statue of Christ by Dannecker, erected in 1824 by Maria Feodorovna at a cost of 30,000 roubles. In the armoury is a large collection of armour, weapons, dresses, and relics of historical persons, while the model-farm contains Tyrolese, Swiss, and Dutch cattle, besides buffaloes and bisons. N.W. of the town is Pulkova, the central Russian observatory. Since 1841, T. has been the scene of great annual horse-races. Pop. (*St. Petersb. Cal.* 1878) 14,165.

Tschi'ta, or **Chi'ta**, the capital of the Russian province of Transbaikalia, Siberia, on the river Ingoda, an affluent of the Amoor, at the base of the Yablonoi Mountains, 255 miles S.W. of Nertchinsk. It has great fairs, and is an important place of trade. Pop. (1873) 2598.

Tschu'di, Egid'ius, or, as he wrote himself, **Gilg Schudi**, the father of Swiss history, was born at Glarus in 1505, of a family of which several members have been distinguished in war, politics, and science [see Blumer, *Das Geschlecht der T. von Glarus*, St. Gallen 1853]. He studied under Glarean in Basel and Paris, was in 1533 and 1549 high bailiff at Baden, and for some time a captain in the French service, afterwards travelling much among the Swiss mountains in search of materials for his historical studies. T. several times acted as a mediator in the religious disputes of his time, but himself continued a Catholic. In 1558 he became 'Landammann' of Glarus, in 1559 he was envoy to the Kaiser Ferdinand I. He died February 28, 1572. The chief of his numerous historical works is the *Chronicon Helveticum*, embracing the period 1000-1414 (*editio princeps*, edited by Dr. J. L. Iselin, 2 vols. fol., Basel, 1734-36). The dramatic descriptions of this book Schiller declared to be 'both homely and Herodotean, nay Homeric,' and used amply in giving local colour to his *Wilhelm Tell* (q. v.). Rilliet (*Les Origines, &c.*, p. 290) notes that it was T. who first gave precision to the circumstances, dates, and persons of the Tell legend. Many unpublished MSS. of T. are preserved in the libraries of St. Gallen and Zürich. See Fuchs, *Ægidius T.'s Leben und Schriften* (2 vols. St. Gallen, 1805); Vogel, *Ægidius T., als Staatsmann und Geschichtsschreiber* (Zür. 1856).—**Johann Jakob von T.**, traveller and naturalist, born at Glarus, July 25, 1818, studied at Leiden, Neuchâtel, Zürich, Paris, Würzburg, and Berlin, travelled in Peru 1838-43, and in 1857-59 visited Brazil, the La Plata States, Chili, Bolivia, and Peru. In 1859 he was appointed Swiss ambassador to Brazil. After his return (1861) he was appointed ambassador to Vienna. His works are *System der Batrachier* (Leiden 1838), *Untersuchungen über die Fauna Peruana* (St. Gallen 1844-47), *Peruanische Reiseskizzen aus dem Jahr* 1832-42 (*ib.* 1846), *Die Kechuasprache* (2 vols. Vien. 1853), *Reise durch die Andes von Süd-Amerika* (Gotha 1860), *Die Brazilianische Provinz Minas Geraes* (*ib.* 1863), *Reisen durch Süd-Amerika* (5 vols. Leips. 1866-68).

Tset'se (*Glossina morsitans*), a genus of *Muscidæ*, or flies, inhabiting Southern Africa, and noted for the fatal effect of their bite on cattle. The average size of the T. is that of the house-fly. Its colour is brown, striped with four bars of yellow across the abdominal segments. The horse, ox, and dog are equally affected by its bite, according to Dr. Livingstone; whilst man, the mule, ass, antelope, and wild game at large, appear to escape injurious effects.

Tu'am, an old episcopal city and market-town of Ireland, in Galway, on the Harrow, an affluent of the Clare, 125 miles W. of Dublin by rail. It is the seat of a Roman Catholic archbishop (since 1152), under whose immediate direction is the theological college of St. Jarlath. The Roman Catholic cathedral, a modern structure, and one of the finest in Ireland, stands on an elevation to the E., and is cruciform, with a tower and six turrets at the angles. The Protestant see of T. became suffragan to that of Armagh in 1839, and the cathedral of St. Mary was re-opened in 1878 after restoration at a cost of £15,000. There are good Franciscan schools, and the trade, which is local, is chiefly conducted at the weekly markets and the nine annual fairs. T. has two weekly

newspapers. Pop. (1871) 4938, of whom 4286 were Roman Catholics. In the Irish *Annals* T. is called *Tuaim-da-Ghualaun*, 'the tumulus of the two shoulders,' 'evidently from the shape of the ancient sepulchral mound from which the place has its name' (Joyce, *Irish Names of Places*, Dub. 1869).

Tuar'icks or **Tawâr'ek**, more correctly **Tuar'eg** (pron. Tuarej), a nomadic race of Berber origin inhabiting the Sahara between 5° W. long. and 13° E. long, and across its entire breadth. They are the finest of the Sahara races, being handsome and powerfully made, but are fierce and perpetually at war among themselves. They profess Islamism, but are more influenced by pagan superstitions. Their women go unveiled, and take part in public affairs. No reliable estimate of their numbers can be formed. T. is a name of Arabic origin, and *Imoshagh* is the name by which the T. designate themselves. They appear to be a race dating from remote antiquity, and Barth identifies them with a people figured on the Egyptian monuments.

Tu'ber, in botany, is the name given to a thickened, fleshy, underground stem, with usually very small leaves which can be made out only in the young state, but having in some cases, as in the potato, a number of buds concealed in depressions termed *eyes*. Many plants form only one tuber; others, several. Roots also are called *tuberous* when either the main root or its branches are thickened into one or more fleshy masses known as tubers.

Tu'bercle is described by pathologists as being of two kinds, the grey or miliary, and the yellow or crude; but the latter is, strictly speaking, a secondary form of the former. Grey, or miliary T., is 'a greyish-white, translucent, non-vascular body, of firm consistence and well-defined spherical outline, usually about the size of a millet-seed. Although in its earlier stage it is uniformly translucent, its central portions quickly become opaque and yellowish, owing to the retrograde metamorphosis of its component elements. In structure, T., like the other *lymphomata*, consists of lymphatic cells contained in the meshes of a very delicate reticulum. The cells are mostly round, or roundly oval, colourless, transparent, and slightly granular bodies, much resembling lymph corpuscles; and, like these, varying considerably in size. Many of them contain a small distinct nucleus. In addition to these are a few larger cells, containing two or even three nuclei.' Masses of T. may be intersected by vessels belonging to tissues interposed between the component parts of the mass, which softens into a yellow caseous substance called the yellow or crude T. Mixed with these masses of T. there are also 'ill-formed epithelial cells, masses of pigment, crystals and plates of cholesterine, remnants of enclosed and disintegrating tissue, which break down and involve the neighbouring tissues, forming strumous abscesses and ulcers. In some cases the process of softening commences in the tubercular mass, and involves the tissues secondarily; in other cases the softening or inflammation commences in the neighbouring tissues, and gradually invades the tubercles; or the latter may harden, leaving a hard chalky mass called the cretaceous T. In some cases this mass may remain innocuous; but it may give rise to suppuration and be thrown off, a condition frequently met with in phthisical patients.

Pathologists are divided in opinion as to whether there is anything essentially peculiar in T., or if it is merely a form of chronic inflammatory deposit. The researches of recent physiologists have shown that by the inoculation of non-tubercular products, or by artificial irritation of the tissues in the lower animals, products undistinguishable from T. may be generated. If these experiments are applicable to man, the deposit of T. may be regarded as only a more definite form of chronic inflammatory lymph, or as a degraded condition of the nutritive material from which old textures are removed and new ones formed, differing in its origin from the normal plasma or coagulable lymph, not in *kind*, but in *degree* of vitality and capacity of organisation. Others, however, maintain that T. is essentially a morbid product, as distinct as cancer, and that its development depends on a peculiar diathesis, viz., the strumous, scrofulous, or tubercular diathesis.

Tuberculosis, in the human subject, may depend on the development of tubercle as a primary, morbid product, or it may be the result of some exhaustive, suppurative lesion. T., or the tubercular diathesis, is, according to Sir W. Jenner, a form of the strumous diathesis, the leading pathological changes of which are fatty degeneration of the liver and kidneys, deposits or formations of tubercle and their consequences, inflammation of the serous membranes.

It has long been firmly believed in Italy that T. is contagious; and there are instances in which it would appear to be communicable, especially in crowded ships, barracks, and rooms. Dr. Farr says:—'The presence of phthisis in the armies of Europe is probably due, in fact, to the inhalation of expectorated tubercular matter, dried, broken up into dust, and floating in the air of close barracks.'

Causes.—T. is undoubtedly, in some instances, a hereditary disease, the germs of which are born with the individual, and ready to be developed on the least exciting cause; but it is very doubtful whether it is generally so, and we believe that this influence has been very much exaggerated. Impure air, density of population, and overcrowding, have much to do with the development of T. Drs. Bowditch and Buchanan, by independent investigation, have successfully established the fact that there is a decided relation of cause and effect between dampness of soil and consumption. According to Dr. Andrews, of the Chicago Medical College, T. is most abundant near the sea, and diminishes as we recede from it. At equal distances from the sea it prevails at the N. and diminishes towards the S. See PHTHISIS.

Tu'berose (*Polianthes*), a genus of bulbous *Liliaceæ* with creamy-white flowers and long and sword-shaped leaves. The elegant and fragrant T. of gardens and conservatories is *P. tuberosum*, a native of America. It is not only a great favourite in civilised countries, but is highly prized by the natives of the Malay Archipelago, where it is called 'mistress of the night,' its odour being most powerful in the absence of sunlight. In the S. of France the T. is largely grown for perfumery. In parts of Italy it is much cultivated to supply the export demand for the bulbs. The old name of the plant was *Hyacinthus tuberosus*.

Tubic'ola, or **Ceph'alobranchia'ta**. See ANNELIDA.

Tubicol'idæ, or **Gastrochœ'nidæ**, a family of *Lamellibranchiate* Mollusca, in which the shell is equivalve and gaping, and is often cemented to a limy tube. See GASTROCHÆNA.

Tü'bingen, a town of Würtemberg, S. Germany, in the Black Forest district, on a hill on the Neckar 1043 feet above the sea, 25 miles S.S.W. of Stuttgart by rail. The streets are old and irregular, the suburbs new and tasteful. The chief buildings are the Schloss *Hohentubingen* with a fine portal, the University (completed 1845), the Rathhaus, and the Gothic Stiftskirche (1468-83), with the monuments of twelve princes (mostly of Wurtemberg). In 1873 a monument was erected to the poet Uhland, who lived here at the foot of the Oesterberg. The University was founded in 1477 by Eberhard im Bart, Graf of Würtemberg, and consisted of four faculties till 1817, when the Catholic College at Ellwangen was joined to it as a faculty of Catholic theology. In 1818 faculties of economics and natural science were added. Connected with the University (which in 1878 had 87 teachers and 1144 students, a number never reached before) are a library of 220,000 vols., a physiological and anatomical institute, a botanic garden, three chemical laboratories, various scientific collections, a large collection of coins and medals, an observatory (in the Schloss), and a philological seminary. T. has also an Evangelical Theological Seminary, the so-called 'Stift,' founded 1537, a Catholic 'Konvikt,' a gymnasium, and a Realschule. The chief industries of T. are the manufacture of cloth, surgical and other scientific instruments, dyeing, and book-printing. There is a large book-trade; fruit, hops, and wine are largely produced in the neighbourhood. T. was taken by the French in 1647 and 1688. On the latter occasion its walls were demolished. Pop. in 1875 (with the garrison) 10,471 (1266 Catholics and 75 Jews). See Eifert, *Geschichte der T.* (Tub. 1849); Klupfel, *Die Universitat T.* (Tüb. 1877).

Tubip'ora, a genus of *Sclerodermic Corals*, belonging to the order *Alcyonaria* (q. v.) and family *Tubiporidæ*. It is represented by the *T. musica*, or organ-pipe coral, the 'pipes' of the coral representing the *thecæ* or coral-cups. No *septa* or internal partitions are developed. The coral itself is dark red in colour, and the polypes are green, and have eight pinnate tentacles surrounding the mouth. The tubes or pipes of the coral are united by cross partitions of external nature, named *epithecæ*.

Tu'bular Bridge, a bridge formed of a large tube, through the centre of which a railway or roadway passes. A T. B. constructed of timber was thrown over the Rhine at Schaffhausen in 1757; but the most celebrated examples of this kind of girder-bridge—viz., the Britannia T. B. (q. v.) across the Menai Straits, and the Victoria Bridge built over the St. Lawrence at Montreal—are composed of wrought-iron plates riveted together. Some idea of the magnitude of the latter, and engineering difficulties attending the construction, may be formed from the following details:—Total length of the Victoria Bridge, 9144 feet; length of tubes, 6592 feet; weight of iron in the tubes, 9044 tons; area of the surface of the iron work, 32 acres; number of stone piers (60 feet high), 24, with 25 spans; the central one is 330 feet, the others from 242 to 247 feet. The total cost was £1,250,000. See BRIDGE.

Tubula'ria, a well-known genus of Zoophytes or *Hydrozoa*, belonging to the order *Corynida*. *T. indivisa* is a familiar British species, the polypites being enclosed each in a straw-coloured tube. The polypites of T. are provided with two sets of tentacles, one set being much larger than the other, and the generative buds being produced at the bases of the tentacles.

Tu'bulibranchia'ta, a term occasionally applied to a division of *Gasteropoda* (q. v.) in which the gills are placed behind the heart, the shell being tubular, and being either of straight or twisted conformation.

Tuck'er, Abraham, an English philosophical writer, the son of a London merchant, was born September 2, 1705. In 1721 he was entered as a gentleman commoner at Merton College, Oxford, and about three years later he proceeded to the Inner Temple; but the fortune which he had inherited from his father relieving him from all personal need of a profession, he gave up the thought of practising at the bar, and having in 1727 purchased Beckworth Castle, near Dorking, he settled down as a country squire. His leisure was at first divided between farming and philosophy, but after the death of his wife in 1754 the latter became decidedly the predominant occupation of his thoughts, and in 1763 he published, under the title of *Free Will*, a tentative specimen of a great philosophical treatise. To a criticism on this portion he replied in the same year by *Man in Quest of Himself, by Cuthbert Comment*, and at length in 1768 he brought out the first three volumes of the extended work as *The Light of Nature Pursued, by Edward Search, Esq.* The remaining volumes, four in number, did not appear till after his death, which happened in 1774. Though painfully destitute of system and ostentatiously prolix in the treatment of his themes, which range over the whole ground of morals and natural religion, T. has succeeded, by the charm of a spontaneous and vivacious style and the deeper charm of an earnest and yet cheerful and charitable spirit, combined with no small ingenuity of exposition and even originality of thought, in securing the grateful suffrages at once of the professional philosopher and the man of letters—of a Paley and a Hazlitt, of a Mackintosh and a Leigh Hunt. His *Light of Nature* has been frequently reprinted: Hazlitt brought out an abridgment of it in 1807. See *Life of A. T.*, by his grandson, Sir Henry Mildmay, originally prefixed to the edition of 1805.

Tuck'ermann, Henry Theodore, an American author, was born in Boston, U.S., April 20, 1813. He travelled in Europe, resided for some time in Italy, and finally in 1845 settled in New York, where he died, December 17, 1871. Besides contributing freely to periodical literature, he published a large number of separate works, of which it is sufficient to mention *The Italian Sketch-Book* (1835), *Sicily, a Pilgrimage* (1839), *Artist Life* (1847; 5th ed. 1867), being sketches of twenty-three American painters; *Memorials of Horatia Greenough* (1834), *Maga, Papers about Paris* (1867), and *Life of John T. Kennedy* (1871). He also did a good deal of work as an editor.

Tucum and **Tucuma Palms**. See ASTROCARYUM.

Tucuman', a province of the Argentine Republic, has an area of 23,386 sq. miles, with a pop. of 108,953 at the census of 1869. It has a delightful climate, and is very fertile, its chief productions being sugar, wheat, rice, and tobacco; wool, hides, and leather are also exported. The chief town, San Miguel de T., is 767 miles N.W. of Buenos Ayres by rail, and has a pop. of 11,000. It has a cathedral and several convents, and carries on manufactures of sugar, brandy, leather, and saddle-cloths. The declaration of the independence of the republic was signed here on 25th March 1816. The railway from T. to Rosario (q. v.), 586 miles long, was opened 1st November 1876.

Tude'la, the second town of Navarre, Spain, on the Ebro, here crossed by a bridge of seventeen arches, is 47½ miles by rail N.W. of Saragossa. The streets are narrow and irregular, but T. contains several fine promenades and squares, an old castle, and fifty churches. About four miles below the town, the canal known as El Bocal del Rey joins the Ebro, and affords a useful outlet to its industries. These are chiefly cloth and silk goods, soap, and earthenware. Pop. 7300. T., the Roman *Tutela* (watch-tower'), was conquered by the Moors in the 8th c., but after several vicissitudes was finally recovered in 1141 by Alfonso V. On November 23, 1808, the Spaniards under Castaños surrendered here to the French under Moncey and Lannes.

Tu'dor (Cymr. *Tewdyr* = Theodore), the surname of an English dynasty (1485-1603), whose founder, Owen-ap-Meredith-ap-T., a simple nobleman of Wales, married in 1423 Catharine, widow of Henry V. and mother of Henry VI. By her he became the father of Edmund Earl of Richmond, and Jasper Earl of Pembroke, and espousing with them the Lancastrian cause, he fell at Mortimer's Cross (1461). Edmund married Margaret, daughter and heiress of John Beaufort (q. v.); and the fruit of this marriage, Henry VII. (q. v.), founded his claims on his descent from John of Gaunt. He was the father of Henry VIII., the grandfather of Edward VI., Mary, and Elizabeth, and the great-great-grandfather of James I. by his daughter Margaret's marriage with James IV. (q. v.) of Scotland. See Gairdner's *Houses of Lancaster and York* (Lond. 1874).

Tu'dor Style, a term in architecture usually applied to Late Perpendicular (q. v.), but sometimes to Perpendicular generally, or to Elizabethan.

Tues'day (Old Eng. *Tiwesdæg*, 'day of Tiw' or 'Tiu') preserves the name of the Eddic god *Tyr* (q. v.), the old Norse *Tysdagr* ('Tyr's day;' comp. Lowl. Sc. *Tysday*), answering to the Lat. *dies Martis* (Fr. *Mardi*).

Tuff, or **Tu'fa**, a rock formed of volcanic material, such as cinders, ash, and lava, mixed loosely together or cemented into a coherent whole. If formed under water, it frequently contains organic remains.

Tuil'eries, Palais des, so called from the tile-fields which formerly occupied its site upon the banks of the Seine, is probably more rich in momentous historical associations than any other single building in the world. In 1518 Louis de Savoie, the mother of François I., acquired the ground, along with a small mansion erected upon it, by purchase from a certain Sieur de Villeroy. The present palace, or rather, since its destruction by the Commune, the late palace, was begun by Delorme, at the command of Catherine de Medicis. It first appears prominently in history as the scene of the royal marriage-fête which preceded by four days the Massacre of St. Bartholomew. The building was added to and improved by all the subsequent kings down to Louis XIV., and was at one time or another occupied by almost all of them. One of its halls, too, was the scene of the early triumphs of the Opera and the Comédie Française, and it was within its walls that the famous representation of Voltaire's *Irène* took place on the 30th of March 1778, so soon to be followed by the death of the almost deified poet. It is useless here to attempt to sketch the stirring and terrible scenes which took place within and around it during the Revolution, when it was the residence of Louis XVI. and the place of meeting of the Convention. Napoleon I. made it his favourite place of abode, and throughout the present century it has been the residence of the various rulers of France, and the scene of many of the most important acts in the frequent revolutionary dramas. Destroyed by the Commune, May 24, 1871, it is already partly rebuilt, and is apparently to be used as Government offices, while the President of the Republic occupies the Elysée Palace. See H. Robinson's *Parks and Gardens of Paris* (Lond. 1878).

Tu'la, a government of Central Russia, bounded N. by Moscow, E. by Riazan and Tambov, S. by Orel, and W. by Kaluga. Area 11,955 sq. miles; pop. (1870) 1,167,878. The surface is in general level, somewhat elevated on the banks of the Oka and Upa. It is abundantly watered by the headwaters of the

Don, and by the Osetr, Plava, and Upa, affluents of the Oka, the boundary river on the N. The soil is very fertile, 70 per cent. is arable, 10·6 meadow, and 8·6 woodland. The chief productions are corn, beetroot, tobacco, flax, and hemp. T. has also extensive cattle-rearing, and active manufactures of linens, cloth, sugar, and hardware.—**T.**, the chief town, is situated at the junction of the Tuliza with the Upa, 112½ miles S. of Moscow by rail. It is the residence of a civil and military governor, and of an archbishop, and has a religious seminary, a gymnasium, twenty-eight churches, a theatre, and an industrial museum. T. is the Liège or Birmingham of Russia, and has extensive manufactures of iron and steel wares. Its physical and mathematical instruments and cutlery are of fine quality. The royal small-arms factory, founded by Peter I. in 1712, employs 7000 men. T. has also large manufactures of fancy wares, soap, sealing-wax, candles, hogs' bristles, and leather. Pop. (*St. Petersb. Cal.* 1878) 57,374.

Tu'la Metal, a silvery alloy, having a greyish tinge, composed of silver, with small proportions of lead and copper. It is the basis of the famous Russian niello snuff-boxes, &c., popularly known as platinum boxes.

Tu'lip (*Tulipa*), a genus of bulbous *Liliaceæ*, with usually solitary campanulate flowers of six free segments; stamens hypogynous, filaments short, anthers fixed by the base, mobile, linear, bursting inwards; ovary three-cornered; stigma sessile with three radiating lobes; capsule erect, coriaceous. The genus is restricted to the Old World, extending from Western Europe to Japan and the Himalayas; there are about 45 species, of which one is found in Britain. The common garden T. (*T. Gesneriana*) has been cultivated away from its native country of S. Russia and Armenia for upwards of three centuries. The first description given of it is by Conrad Gesner, in a memoir published in 1561. He had seen it in bloom in April 1559 at Augsburg, in the garden of Herwart, who had received the seeds from Byzantium—probably from Dr. Busbecq, who knew the plant as grown by the Turks. It spread rapidly and appeared in most of the botanical books of the second half of the 16th c. Into the Netherlands it was introduced in 1571, into England in 1577 (by James Garret), and into France by Peiresc, who cultivated it in 1610 at Aix, having received it from Tournay. The taste for the T. has since increased, and their bulbs have become an article of commerce; it was carried to a ridiculous extent, and the T. mania reached its height in Holland from 1634 to 1637. At the beginning every one won in the speculation, which was conducted much on the same principle as 'time-bargains' on the Stock Exchange at the present day. But the time soon came when the contracts could not be carried through, and multitudes were ruined. Then the Dutch government interfered and the gambling was crushed. To develop all the beauty of form and colour of which the T. is susceptible requires the greatest care in its cultivation. From seed new varieties are raised, the seedlings blossoming at four to seven years. Hundreds of varieties have been established from time to time, which range under four groups—Bizarres, Byblœmens, Roses, and Selfs. The first have a yellow ground marked with purple or scarlet; the second a white ground variegated with violet or purple of various shades; the third are marked with rose, scarlet, or crimson on a white ground; and the fourth or plain-coloured T. have a white or yellow ground without any marks. The first three of these families are again divided into feathered and flamed according as the intermingled colours are in narrow or broad stripes. Various other species of *Tulipa* are now represented in all good collections of bulbous plants, and the early-flowering fragrant *T. suaveolens* is often seen in window culture. The yellow-flowered *T. sylvestris*, which is naturalised in several parts of Britain, is probably native in Norfolk and Suffolk. It is common in Europe, and in Siberia its bulbs are eaten. T. is derived from the Turkish word *tulipan*, a 'turban,' the rich and varied flowers resembling an inverted cap.

Tu'lip Tree (*Liriodendron tulipifera*) is one of the most magnificent forest trees of temperate N. America, attaining in favourable situations a height of 100–140 feet, with a straight, clear trunk 6–9 feet in diameter. It is the only species of the genus—which belongs to the Magnolia family—and may be recognised by its large three-lobed leaves, with the middle lobe cut square at the end, and large solitary tulip-like flowers having greenish sepals and petals variegated with yellow and orange. The wood is highly esteemed, uniting lightness with strength and durability. It is of a pale-yellow colour, fine-grained, compact, is easily worked, takes a good polish, and is much used by house and bridge constructors, by cabinetmakers, coachbuilders, implement-makers, &c., and by the Indians for canoes. The bark is officinal in the secondary list of the United States Pharmacopœia as a stimulant, tonic, and diaphoretic. The noble appearance of the tree led to its introduction more than 200 years ago into Europe (see Evely's *Sylvia*), where it is appreciated as a great ornament for pleasure-grounds, &c.

Tullamore' (Irish Gael. 'the great hill'), the county town of King's County, Ireland, is situated on a river of the same name, 57 miles S.W. of Dublin by a branch line of the Great Southern and Western Railway. It occupies an oasis in the Bog of Allen, and, owing to its central position, is a place of some importance, having several churches and schools, a county gaol, and infirmary. Besides the railway, it has communication with Dublin and the Shannon by means of the Grand Canal, and does a considerable business in brewing, tanning, &c. Its trade in corn, at one time very large, has much fallen off since the repeal of the Corn Laws. Pop. (1871) 5179, of whom 4597 were Roman Catholics.

Tulle, a town in the department of Corrèze, France, on the Corrèze, 20 miles N.E. of Brive. It is an ill-built but finely-situated town with a much-admired cathedral presenting a mixture of the Gothic and Classical styles. The Maison Sage and a square tower attributed to the Romans are the other buildings of note. T. has manufactures of arms, leather, lace (*Point de T.*), &c., and carries on a trade in iron and agricultural products. Some say it takes its name from a Roman fort called *Tutela;* more probably it first sprang up in the 14th c. round a monastery. Pop. (1872) 11,848.

Tulle, a delicate bobbin-net of silk used for millinery purposes.

Tull'och, the Rev. John, D.D., a Scotch theologian and author, was born June 1, 1823, near Bridge of Earn, Perthshire, studied at the University of St. Andrews, and in 1844 was licensed as a preacher in the Church of Scotland. After holding for some years a charge in Dundee, he was in 1849 presented to the parish of Kettins in Forfarshire, and in 1854, on the death of Dr. Haldane, was appointed Principal of St. Mary's College, University of St. Andrews, an office which he still (1879) holds. T. first attracted notice as a writer in the *British Quarterly* and *North British Review*. In 1855 he obtained the second Burnett prize (£600) on the 'Being and Attributes of God,' and his essay was published under the title *Theism*. Since then T. has been a prolific contributor to the religious and philosophical literature of the day, much of his work being first given to the public through the medium of the lecture-room, and afterwards collected into separate volumes. Of these the most important are *Leaders of the Reformation* (1859); *English Puritanism and its Leaders* (1861); *Beginning Life, Chapters for Young Men* (1861); *The Christ of the Gospels, and the Christ of Modern Criticism* (1864); *Rational Theology and Christian Philosophy in the Seventeenth Century* (2 vols. 1872); *Religion and Theology, a Sermon for the Times* (1875); *Facts of Religion and of Life* (*Sermons*) (1876); and *Pascal* in Blackwood's series of 'Foreign Classics' (1878). In the spring of 1879 T. delivered two very striking lectures at the Edinburgh Philosophical Institution on *The Intellectual and Literary Revival in Scotland in the 18th C.* In 1878 he was chosen Moderator of the Church of Scotland, and discharged the duties of the office with singular dignity and tact. In politics and theology he is a pronounced liberal. He does not believe in the survival of a narrow Establishment; and strenuously and incessantly pleads for as wide a measure of intellectual toleration as is consistent with the claim of Christianity to be received as a unique revelation of religious truth. Of late years T. has been generally recognised as the leader of the 'Broad Church' party in that Communion. In all his work there is the evidence of a masculine, incisive mind; and he speaks and writes with ease, elegance, and force.

Tumkur, the chief town of the district of the same name, in the State of Mysore, India, 43 miles N.W. of Bangalore. It is prettily situated, and surrounded by fruit-trees. Pop. (1871)

11,170.—The *district* of T., which averages 2500 feet above the sea, has an area of 3606 sq. miles; pop. (1871) 632,239. The crops are *ragee*, rice, cocoa-nut, and areca palms. The through traffic, in the hands of *lingayat* merchants, is considerable. The manufactures are cotton cloth, blankets, iron and steel, brass ware, and earth-salt.

Tu'mours (Lat. 'swellings') may be defined as new formations or additions to some parts of the body of a substance organised or partly organised, and not the result of inflammation only. There are some T., however, which owe their origin to inflammatory processes, and there are others which occur congenitally as the result of fœtal inclusion from an abnormal and excessive formation of epidermal tissue, or from obscure causes. The causes operating towards the formation of T. are quite unknown. Hereditary influence is often traceable, more especially in those of a malignant nature; but no reason is known why the disease, after it has been once originated, should be transmitted from generation to generation. There are three well-marked classes of T. which are distinguished from each other both clinically and anatomically. In the one class (*homologous* T.) the substance of the tumour has an anatomical resemblance to some tissues of the body. Such T. gradually increase in size, and displace the neighbouring tissues without invading them. Such are called innocent T., as they in general only produce inconvenience from their bulk, though they may produce fatal results from being situated in a vital part, and from interfering with vital functions. The second class (*heterologous* T.) bear no resemblance, in their substance, to normal tissues; and they are called *malignant* T., as they affect the mass of the blood, causing cachexia and death. Such T. are extremely liable to ulceration, and they invade all the textures of the part in which they grow. When excised they are apt to reappear in remote parts of the body. The third class of T. (*semi-malignant*) differ from the two former classes, both anatomically and clinically, as they very closely resemble in structure the part in which they grow, or the embryonic state of some natural organ of the body. Such T. may recur after complete removal, they may gradually spread to all the neighbouring tissues, and they may ultimately destroy life by ulceration; but they do not affect the lymphatic system, nor make their appearance in remote parts of the body after excision.

Innocent T. are divided into cystic and solid T. The former have been described under Cysts (q. v.). The latter include: *Fatty* T., usually springing from the natural fat of the subcutaneous membrane, or in connection with deeper-seated fat, and attaining a great size; *fibrous* T., harder, rounder, and less adherent to the skin than the fatty, and occurring in connection with the uterus, the nerves, the bones, the testicles, and many other parts of the body; *fibro-cellular* T., containing, in addition to the fibrous element, a variable proportion of cells; *cartilaginous* T., or Enchondromata, generally occurring as outgrowths of the bone, but also in the parotid gland, the testicle, the thyroid body, and other parts; *bony* T., which are rare; and *vascular* T., large, irregular, pulsating masses, composed of enlarged vessels, which may be either arterial, capillary, or venous. See ANEURISM, NÆVUS, CANCER, SARCOMA, and OVARIES, DISEASES OF THE.

Tun (Old Eng. *tunne*, a 'vat tub'), originally a large vessel or cask, but used subsequently as a measure of capacity in various countries. In Britain it was used for liquids, containing 216 gallons for ale and beer, and 231 for wine. A T. of water weighs a little over 2000 lbs., and hence probably the origin of the Ton (q. v.) weight. The measure is not now legal.

Tun'bridge, a quiet country town of England, county of Kent, on the Medway, 5 miles N. of T. Wells, and 27 S.E. of London by the S.-Eastern Railway. It consists of a main street and the growing district of St. Stephen's, and near the bridge over the Medway, which here splits up into several streams, stands the castle (1259), with its well-preserved gatehouse of rich Early Decorated character, having round towers at the angles. In the inner ward are some Norman walls, and the mound on which stood the keep built by the original possessor, R. de Fitz-Gilbert, who had exchanged a manor with the Archbishop of Canterbury. To him succeeded the De Clares, Audleys, and the Staffords, the present family. The old parish church was virtually rebuilt (1877-78) at a cost of £9000. The grammar-school, founded by Sir A. Judd (Edward IV.), rebuilt in 1865, is one of the most richly endowed of the Public Schools (q. v.). The building bears the arms of the founder, and of his Skinners' Company. The new public hall (1875) has a tower 74 feet high. There is a factory of T.-Ware, and the town is encircled by hop-gardens. Pop. (1876) 8209.

Tun'bridge-Ware, a kind of mosaic woodwork, applied to workboxes, desks, cigar-holders, and fancy articles, formerly much made at Tunbridge Wells, but now little seen.

Tun'bridge Wells, an old, fashionable English watering-place, charmingly situated, partly in Kent partly in Sussex, 5 miles S. of Tunbridge by rail. Its chalybeate springs, discovered by Lord North in 1606, were visited by Charles I.'s queen, Henrietta, and immediately became a resort alike of Cavaliers and Puritans, the latter leaving abiding traces not only in the names of Mount Ephraim, Mount Sion, Mount Pleasant, &c., but in the quiet, subdued character for which the place is still remarkable. The chief parade, called the Pantiles from having been paved with pantiles (at the cost of Queen Anne), has interesting associations with Dr. Johnson, Beau Nash, Richard Cumberland, and other celebrities. Here and in the High Street are the principal bazaars and shops for Tunbridge Ware (q. v.). At one end of the Pantiles are the Wells, the waters of which contain steely particles, marine salts, oily and ochreous matter, and a volatile vitriolic spirit. The old church of King Charles the Martyr is built in two counties and three parishes. A new church of St. Peter was opened in 1875, a new Pump-Room in 1877, and a Friendly Societies' Hall in 1878. There are many beautiful drives and elegant mansions in the vicinity. The 'season' extends from July to September. Pop. (1871) 19,410.

Tûn'dras. See SIBERIA.

Tune, in music, may mean a melody or air, also correct intonation or pitch.

Tung'sten, or **Wolf'ram** (W = 184), a white, hard, brittle, and heavy metalloid, occurring as tungstate of iron and manganese in the mineral *wolfram*, which is tolerably abundant in Cornwall. It is usually classed with uranium and molybdenum. Heated in chlorine, it forms the *hexchloride* (WCl_6), which if heated in hydrogen may be transformed into the lower chlorides (WCl_5, WCl_4, WCl_2). T. forms three oxides (WO_2, WO_3, W_2O_5), none of which are basic. Tungstic acid (H_2WO_4) unites with bases in various and often unusual proportions. It exists in two isomeric modifications, ordinary tungstic acid which forms insoluble salts, and metatungstic acid which forms soluble salts. T. also forms two sulphides, the disulphide (WS_2) and trisulphide (WS_3), the latter of which unites with basic metallic sulphides forming *sulphotungstates*, analogous in composition to the normal *tungstates*.

Tungûs', a nomadic people in E. Siberia, belonging to the Mongolian race. Estimated at 70,000 in number, the T. are scattered from the Taimyr Peninsula on the Arctic Ocean to the Amoor River, and the Okhotsk and Japan Seas. They are divided into several tribes, of which the chief are the Tchaponirs and Orotongs on the Tunguska, the Orotchons, Manegers, Dauers, Manguns, and Golds on the Amoor and its tributaries, and the Shibæ in the Ili Valley. The face of the T. is flat, the beard scanty, and the hair thick, black, and long. They dwell in conical huts of birch bark and skins, and live by reindeer-breeding, fishing, and the hunting of furred animals. In December the T. come in their *narts* ('sledges') to the Russian settlements to pay *yazak* ('tax') to the authorities, and buy salt, powder, and metal wares. Their religion is mainly Buddhism over a basis of Shamanism, though the vigorous efforts of Nicholas I. to convert the T. to the orthodox Greek faith have been partly successful.

Tunica'ta, a class of *Molluscoida* or Lower Mollusca, including animals in which the outer layer of the body or *test* contains cellulose, the mouth opening into a branchial sac or breathing-chamber. The heart is a simple tube, and periodically reverses the direction of its blood-currents. The T. may be simple, social, or compound. They are hermaphrodite for the most part, and undergo a metamorphosis. To the T. belong the familiar *Ascidians* or Sea Squirts (q. v.), and such genera as *Clavellina*, *Salpa*, *Pyrosoma*, *Botryllus*, &c. The nervous system, as in all Molluscoida, consists of a single ganglion placed

between the branchial sac and the atrial sac—the latter being the cavity into which the effete water of respiration passes from the branchial chamber. The atrial chamber opens externally by a special (*atrial*) aperture.

Tu'ning, the correct adjustment of the sounds of a musical instrument. Such instruments as the flute and horn are tuned without difficulty, as, if the pitch is altered by accident, it affects every note, and may easily be rectified by varying the length of the pipe. The notes of the organ and pianoforte, however, are unconnected and independent, and require careful adjustment from time to time (see TEMPERAMENT). Stringed instruments, such as the violin and harp, require T. on every occasion on which they are used.

Tu'ning-fork, a steel instrument with two prongs, designed when set in vibration to give a musical sound of a certain fixed pitch. It was invented by John Shore, sergeant-trumpeter to George I. On account of the difference in the Pitch (q. v.) used at various places, there is considerable variety in the pitch of tuning-forks according to the purpose for which they are required. The ordinary T.-F. sounds only one note (usually C in this country and A in Germany); but some are now made according to a German invention, with a slider on each prong, which, according as it is moved up or down, regulates the pitch of the note produced.

Tu'nis, one of the Barbary States, and a regency of the Ottoman Empire, lies between Algeria and Tripoli, and has an extreme length of 440 miles, with an average breadth of 100 miles, and an area of 45,000 sq. miles. Its N.E. extremity is only 80 miles distant from Sicily. Parallel lines running N.E. and S.W. divide the country into four physical regions as follows: (1) The mountain region in the N., with peaks from 4000 to 5000 feet high. It is well watered, and abounds with oak forests. (2) The Tell, also an upland district, consisting chiefly of plateaux. (3) The Sahel, a region of wide dreary plains, now productive only after the infrequent seasons of heavy rain, but thickly studded with ruins, showing that it once supported a large population. (4) The Sahara, which appears to be encroaching on the more fertile lands. Near the border of Tripoli is the Belad-el-Jerid ('land of dates'), a district rendered fertile by artificial irrigation, the water being obtained from subterranean streams. The only stream in T. worthy of the name of river is the Mejerda (the *Bagradas* of antiquity), in the N. Shallow salt lakes of large size are numerous, and the plains in some parts are strongly impregnated with saline matter. Salt, saltpetre, and lead are the principal mineral products of the country. The climate is salubrious, and less extreme than that of Algeria or Tripoli. Where water is obtainable the land is fertile, and cereals and fruit-trees grow well. Cattle and sheep are reared in great numbers, and T. is also celebrated for its fine dromedaries and horses, the last being much in demand for the French army in Algeria. On the coast, sponge and coral fisheries are carried on by Maltese and Sicilians. The overland traffic with the Sahara, once very important, is now of small dimensions. The exports (olive oil, wheat, barley, esparto grass, wool and woollen manufactures, hides, wax, &c.) from the eleven ports of T. amounted (1875) to £790,140; the imports (cotton and woollen goods, leather, silk, timber, wines, &c.) to £720,570. The population consists of Moors, Arabs, Kabyles (who inhabit the mountain districts), and Jews. The last number 45,000, and are a prosperous community. Under the Romans the population of T. is said to have reached 17,000,000, and 150 years ago it was 5,000,000, but at the present time it is estimated at not more than 1,500,000. Famine, produced by drought, and epidemics—notably in 1785, 1829, and 1867—have brought about the diminution. T. was conquered by the Turks in 1575, and paid tribute to the Sultan till October 25, 1871, when he renounced it. The country is ruled by a Bey, who is hereditary, but receives his investiture from the Sultan of Turkey, and is forbidden to declare war, make peace, or cede territory without the permission of his suzerain, whose effigy is borne on the coinage. The Bey is officially styled 'Possessor of the Kingdom of T.,' and in all respects other than those specified his authority is absolute. Besides the capital, T., the chief towns of the country are Susa, Sfax, Monastir, Bizerta, and Kairwan (q. v.). See Rae, *Country of the Moors* (1877), and Desfossé's *La Tunisie; Histoire, Finances, Politique* (Par. 1877).

Tu'nis, capital of the country of the same name, is situated at the head of a salt lake, nowhere more than 6 feet deep, which communicates by a narrow channel with the Gulf of T., an inlet 30 miles long. At the outlet of the lake is situated Goletta, the port of T., whose harbour is a roadstead with good anchorage, and is sheltered except from the N. It was entered (1875) by 632 vessels of 111,091 tons, and cleared by 612 of 108,259 tons, the exports amounting to £299,644, the imports to £476,875. Goletta is connected by railway with T., which is a walled, fortified, and straggling city, whose winding streets are now paved and kept fairly clean. The whole town has been built of materials taken from the ruins of Carthage, 13 miles N.E. The bazaars of T. are good, and some of the mosques are splendid edifices, but Europeans are jealously excluded from them. The Bey's palace is a modern building in the Saracenic style of architecture, internally decorated with great magnificence, but with little taste. There is also a Mohammedan college with 100 students. T. has important manufactures of woollen, linen, and silk goods (which are exported to all the Mohammedan countries bordering on the Mediterranean), morocco leather, olive oil, soap, and perfumes. The population is estimated at about 120,000, of whom 30,000 are Jews and 10,000 Europeans, principally Maltese and Italians. A railway is being constructed from the city of T. to Beja (67 miles), and is to be ultimately continued 45 miles farther W. to join the Algerian railway system.

Tunk'ers (Ger. 'Dippers'), corruptly **Dunk'ers**, and otherwise known as **Harmless People**, are a sect of religionists in the United States who draw their origin from Germany, but have been an exclusively American sect since the beginning of the 18th c. They reject infant baptism, have no professional ministry, refuse to take oaths or to fight, accompany the celebration of the Lord's Supper with love-feasts, washing of feet, &c., discourage marriage, and depend on prayer instead of medicine for the recovery of the sick. As a rule, the T. are Universalists (q. v.). They are in good repute among neighbours for honesty and industry. Statistics, as savouring of pride, they do not allow, but in 1875 their number was estimated at 100,000.

Tunn'el and Tunn'elling, A tunnel is a horizontal or slightly inclined archway driven through a hill or under a road or river for the passage of a railway, canal, roadway, or other purpose. Many extensive tunnels were executed by the Romans to convey water to cities; but in point of magnitude and difficulty of construction these ancient structures have been surpassed by modern works. Tunnelling has been extensively carried out on railway lines, wherever 'cuttings' would have exceeded 70 feet in depth, and in places where proprietors, desirous of preserving the amenity of their estates, have forced the work. The fullest display of scientific knowledge and practical skill is called for in designing and executing a tunnel. Except in the want of light, air, and drainage, it is seldom that the conditions affecting the construction of any two tunnels agree. Tunnels are generally straight, sometimes curved; some are mined from the ends without shafts, but most are opened up from shafts sunk along the line of formation. Unless where dry durable rock is perforated, a lining of brickwork or masonry is necessary. The first step in the construction of a tunnel consists in laying down its centre line on the surface of the ground. This is effected with the aid of a transit instrument placed in a wooden observatory erected on an eminence. Shafts are then sunk to the level of the tunnel, and the direction underground is accurately set down. A tunnel 1 mile long may require five shafts, one near each end and three others between. Permanent shafts for ventilation are lined with brickwork, temporary shafts with timber. A 'sump' or pit is constructed at the bottom of each shaft to collect drainage water, which is removed by pumping. Working from the shafts, a small 'heading' is usually formed right through by boring and blasting, connecting the various shafts and marking out the centre line of the tunnel. The enlargement of the 'heading' to the required size of the tunnel then proceeds 'length' by 'length,' one being completed before another is commenced. A 'length' varies from three to six yards, according as the ground is 'heavy' or 'light.' A timber framework is inserted to support the roof until the masonry or brickwork sides and arches are built. When additional working faces are necessary to expedite the work, a 'break-up' is formed in the heading between the shafts by opening up and

completing a 'length' of the tunnel. Drainage is provided for by an inclined conduit beneath the roadway, and ventilation of the works is effected by forcing in fresh air. The work of excavation has of late years been greatly facilitated by the invention of rock-boring machines. Several important tunnels have been constructed in England. The Box Tunnel, on the Great Western Railway between Chippenham and Bath, is 3200 yards long; greatest width, 30 feet; height above the rails, 24½ feet. It has 7 shafts, brick-lined, the deepest being 300 feet. Woodhead Tunnel, near Manchester, is the longest tunnel in Great Britain, and measures 3 miles 26 feet. Since its construction, a second tunnel has been driven through parallel to it. Kilsby Tunnel, on the London and N.-Western Railway, measures 2398 yards in length, and 27 feet by 23½ feet in section. A quicksand was encountered in driving the heading, causing delay and greatly increased expense; the total cost amounted to £125 per lineal yard. Netherton Tunnel, on a branch of the Birmingham Canal, is 3036 yards in length; section 27 feet by 24 feet. It was cut from 17 shafts (10 temporary), the greatest depth being 344 feet. The Thames Tunnel, under the Thames at Rotherhithe, was commenced in 1825 from designs by Sir I. K. Brunel, and after several irruptions of the river, completed and opened as a public footway in 1843. It has a double passage, 400 yards long, and is now used as a railway tunnel. The cost of construction was £1137 per yard. The London Metropolitan Underground Railway also furnishes a remarkable example of tunnelling on an extended scale; but all these achievements pale before the great Alpine tunnels, which are the grandest feats of engineering skill yet undertaken. Mont Cenis Tunnel, which pierces Le Grand Vallon, 15 miles S.W. of Mont Cenis, was commenced in 1857, and opened as a junction between the railways of Savoy and Piedmont in 1871. The northern entrance (3801 feet above sea-level) is situated near Modane, and the southern (4236 feet above sea-level) at Bardonnêche. The dimensions of the tunnel are—length 7·6 miles, greatest width over 26 feet, height at Modane end 24½ feet, and 11 inches more at southern extremity. The gradient rises to the centre, on the French side 1 in 45, and on the Italian side 1 in 2000. The tunnel is one mile beneath the summit of the mountain; shafts were therefore impossible, and the work was carried through by driving galleries from each end. The centre lines met with wonderful exactness. Mont Cenis Tunnel is straight, lined throughout with brick, and the total cost was £167, 12s. per yard. The excavation was greatly expedited by the introduction of M. Sommeiller's rock-drilling machines, driven by compressed air. Mountain streams were used to compress the air, which was led into the galleries through tubes, and after driving the drills the air escaped into the tunnel and served to ventilate it. St. Gothard Tunnel, commenced in the autumn of 1872, now in progress through the mountain of that name, will when completed be 9·24 miles long. The galleries are being driven from Göschenen on the one side and Airolo on the other, and it is expected that they will meet early in 1880. The altitudes above sea-level are—at Göschenen 3703 feet, at Airolo 3850 feet, and at the summit of tunnel 3873 feet. The perforation is being accomplished with 18 to 20 drills, driven by air under pressure of 8 atmospheres, and making 18 to 20 strokes per minute. The Hoosac Tunnel, Massachusetts—the longest in the United States—was commenced in 1856, and after several suspensions of work completed in 1874. It is 4¾ miles in length, is lined with masonry, has a shaft 1000 feet deep, and cost about £180 per yard. The Burleigh compressed-air rock-drill was used in the excavation. A tunnel (total length 4½ miles) to connect the Bristol and S. Wales railways is at present being driven under the Severn. The crowning enterprise in tunnelling will be the Channel Tunnel, which it is proposed to drive from the South Foreland in Kent to a point near Calais, in France, to join the railway system of England with that of the Continent. See C. F. Gripper's *Treatise on T.* (Lond. 1879).

Tunn'y (*Thynnus vulgaris*), a *Teleostean* fish, belonging to the *Scomberidæ* or Mackerel family, and attaining a length of 4 feet or more. Its colour is a dark blue on the upper parts, and silvery white below, the sides of the head exhibiting a white hue. The T. spawns in May and June, and visits the shores in huge shoals, which fall a ready prey to the fishermen. The T. is fished chiefly on the Mediterranean coasts. Large nets are used, as in mackerel-fishing; the T. being enclosed gradually in huge pockets and killed by blows from clubs. The flesh is nutritious and palatable, and is eaten both in a fresh and salted condition. The body is deep in front, but tapers towards the tail. A single dorsal fin is developed, and the tail fin is markedly forked, the tail being keeled on each side. The American T. (*T. secundo-dorsalis*) is common on the northern coasts of America, and is noted for the oil obtained from its head and abdominal viscera; the liver being rich in this product. The Pacific Albacore (*T. Pacificus*) and Bonito (q. v.) are allied species.

Tun'stall, a town of the Staffordshire Potteries, 2 miles N.N.W. of Burslem, on the Grand Trunk Canal, has two churches, Christchurch (new spire 1863), and St. Mary's (1859) in First Pointed style, a town-hall, literary institute, &c. Earthenware and porcelain are largely manufactured, and there are also extensive iron-works, brick-fields, and collieries. Pop. (1811) 1677; (1871) 13,540.

Tu'pelo (*Nyssa*), a genus of *Cornaceæ*, consisting of trees inhabiting the swamps and river-banks of the N. American continent. The Common T. (*N. aquatica*) attains 30-50 feet, and its wood is much used for naves of wheels, &c. *N. multiflora*, the Forest T. or Black Gum-Tree, has a growth like the beech. Its wood serves for wheels, pumps, bowls, mortars, wooden shoes, and various turners' work. The acidulous fruits are made into a pleasant preserve. *N. uniflora*, the Swamp T., grows to 80 feet, and the wood is used for corks and floats.

Tupp'er, Martin Farquhar, D.C.L., F.R.S., was born in London, July 17, 1810, and passing from the Charter House to Christ Church College, Oxford, graduated B.A. (1831). He studied law, and was called to the bar at Lincoln's Inn, but has never practised, residing chiefly at Albury, Surrey, and twice having visited the United States, in 1831 and 1876. Author of over twenty works, this 'Walt Whitman of Philistia' must be widely known by his *Proverbial Philosophy* (4th series, 1838-72), since it has passed through fifty editions.

Tura'nian (from *tura*, 'swiftness'), the title conferred on a vast family of combinatory or agglutinative languages, which is made to comprise every tongue of Asia and Europe that is not either Aryan (q. v.) or Semitic (q. v.), with the exception of Chinese and its cognate dialects. This family falls, according to Max Muller, into two great divisions, the Northern and the Southern; the Northern being subdivided into five classes, Tungusic, Mongolic, Turkic (see TURKISH LANGUAGE), Finnic (see FINNISH and HUNGARY), and Samoyedic; the Southern into four, Tamulic or the Dravidian Languages (q. v.) of the Dekkan, Bhotiya or the dialects of Bhotan and Tibet, Taic of Siam, and Malaic of the Malay and Polynesian islands. Under these nine classes he groups 116 dialects, and even then he does not stretch the term 'T.' to its widest limits, which with many philologists include Accadian, the language of the Chaldæan inventors of cuneiform, and Basque (q. v.), and by some are extended to North America. Naturally there is a dispute as to the correctness of the term at all; and while Max Müller asserts that the T. languages 'share elements in common which they must have borrowed from the same source, and their formal elements are such that it would be impossible to ascribe them to mere accident,' Peile in *Philology* (Lond. 1877) maintains that the title T. 'had better be avoided, as the agglutinative languages are much too different to give any ground at all for believing that they all belong to the same family. They agree only in the general principle of forming their speech; but no common bond has yet been found to bring together the main groups of the so-called T. peoples; and it is not likely there is any.' This principle, the combinatory, described under COMPARATIVE PHILOLOGY, might certainly have been independently arrived at by different nations, and it is equally rash to regard Japanese as necessarily cognate to Finnish because both are agglutinative languages, as it would be to connect the Semitic and Aryan tongues on the score of their common possession of inflection. See Max Müller, *Lectures on the Science of Language* (2 vols. Lond. 1862-64); Sayce, *Principles of Comparative Philology* (Lond. 1874); and Vámbéry, *Etymologisches Wörterbuch der Turko-Tatarischen Sprachen* (Leip. and Lond. 1878).

Tur'bary is a Common (q. v.) of English law, by which one person may have the right to cut turf from the ground of another. The right is usually constituted by prescription.

Tur'berville, George, an English poet, was born at Whitchurch in Dorsetshire about 1530, educated at Winchester and New College, Oxford, became secretary to Sir Thomas Randolph, ambassador at the court of Russia, and died about 1600. T. executed in 1567 two translations from Latin, *The Heroical Epistles of Ovid* (six into blank verse, and the rest into four-lined stanzas), and the *Eclogues of Mantuan*, an Italian poet who died in 1516. In 1570 he published *Epitaphes, Epigrams, Songs, and Sonets; with a Discourse of the Friendly Affections of Tymetes to Pindara, his Ladie*, which has given him a little niche among the Elizabethans. In addition, T. wrote books on *Falconrie* and *Hunting*, and among other things Englished *Ten Tragical Tales out of sundrie Italians, with the Argument and L'Envoye to each Tale* (1576).

Turbin'idæ, a family of *Gasteropodous Mollusca*, represented by the 'top shells,' and having a pyramidal or top-shaped shell, with a horny or limy *operculum*. The typical genus *Turbo* has a turbinated shell with a rounded base. The whorls of the shell are convex, and the aperture is large and rounded.

Tur'bot (*Rhombus maximus*), a species of flat fishes or *Pleuronectidæ* (q. v.), in which the body is of rhomboidal shape, the dorsal fin very long, and the eyes borne as a rule on the left side of the body. Allied to the T. is the well-known Brill (q. v.). The T. may attain a very large size, specimens ranging from 50 lbs. to 90 or 100 lbs. weight being frequently obtained. The upper surface is brown, and bears a number of detached bony tubercles or granules. The chief English T.-fishery is off the S.-eastern coasts of England and in the North Sea. Off the Dogger Bank the T. is also plentiful. The American or Spotted T. (*Rhombus maculatus*), an esteemed table-fish, has its upper surface marked by blotches of rounded outline and dark-brown hue.

Tur'didæ and **Tur'dus**. See MERULIDÆ.

Turenne', Henri de la Tour d'Auvergne, Vicomte de, second son of Henri, Duc de Bouillon, and of Elizabeth, daughter of William I., Prince of Orange, was born at Sedan, 11th Sept. 1611. He was brought up in the Reformed faith. At the age of thirteen he went to learn the profession of arms under his uncles, the Princes Maurice and Henry of Nassau. Recalled (1630) to France by Richelieu, he was made colonel of a regiment, and first distinguished himself at the siege of La Motte in Lorraine. During the retreat of the French army from Mainz (1635), his courage, fortitude, and humanity were conspicuous. In the campaigns of 1637-38 T. captured Landrecies, Soire-le-Château, Maubeuge, Brisach, &c. During 1639-42 he served in Italy, chiefly under the Comte d'Harcourt, winning numerous small victories, and capturing Turin, Moncalvo, Ceva, Mondovi, and Coni. His military reputation was now established, and he received the title of Marshal of France. Towards the close of 1643 T. was sent to the Rhine, and entrusted with the command of the French troops. His achievements during the last five campaigns of the Thirty Years' War covered him with glory, and proved him to be a leader indomitable in spirit and inexhaustible in resource. He captured Philipsbourg and Mainz (September 1644), held in check his three opponents, Mercy, Gleen, and the Duke of Lorraine, saved Speyer and Baccarat, retook Kreuznach, overran during the winter Suabia and Franconia to the gates of Nürnberg and Wurzburg, won the battle of Nordlingen (3d August 1645) in spite of the obstinate rashness of the Duc d'Enghien; drove the Spaniards out of the electorate of Treves; by a rapid and skilful march through Westphalia and Hessen united himself with the Swedes, swept over Suabia and Franconia, invaded Bavaria, was on the point of totally overwhelming the Imperialists, when orders came to withdraw to the Rhine, and, finally (17th May 1648), utterly defeated Montecuculi and Melander at Sommerhausen, on the road to Augsburg. This victory, followed by that of Condé over the Spaniards at Lens, brought about the peace of Westphalia (24th October 1648), and closed the Thirty Years' War. Now followed the troubles of the Fronde (q.v.), in which T. at first took the side of the Frondeurs, and through the seductive influence of Mme. de Longueville was induced to enter into culpable negotiations with the Spaniards for an invasion of France. But after a defeat at Rethel (15th December 1650) he became ashamed of civil war, and returned to his allegiance to the Crown. Condé, meanwhile, had quarrelled with Mazarin, and become a Frondeur. The two greatest generals of the age were now opposed to each other; and the firmness, coolness, and scientific skill of T. proved more than sufficient to baffle and defeat the impetuous valour of his adversary. In 1652 the victories of Targeau (30th March), of Etampes (4th March), of the Faubourg St. Antoine (2d July), together with his later splendid strategy, placed the young king in possession of Paris (21st October). In 1653 he was in command on the north frontier, and frustrated all the attempts of Condé and the Spaniards to penetrate through Picardy; in 1654 he stormed the Spanish camp near Arras, and inflicted enormous loss on the enemy; and in 1658 forced Dunkirk to surrender, after destroying the Spanish army of relief. The fall of Dunkirk was followed by the capture of Bergues, Furnes, Dixmude, Oudenarde, Ypres, Comines, De Gramont, Ninove, &c. The treaty of the Pyrenees (7th November 1659) was the result of the brilliant successes of T. When war broke out between France and Holland in 1667, fortune still attended T. In less than four months he captured Charleroi, Ath, Tournai, Douai, Oudenarde, Lille, and Alost. In 1668 he formally abjured Protestantism after considerable reading and reflection—an act which still further advanced him in the favour of Louis. The war between France and Holland (1672-78) witnessed his last and greatest achievements. His defence of the Rhine with an inferior force, and his invasion of North Germany, were prodigies of military skill and daring; but his devastation of the Palatinate (1674), though done under express orders, has left a dark stain on his reputation. On the 27th of July 1675 he was killed by a cannon-ball at the battle of Salzbach. T. was buried at St. Denis amid a national mourning. As a general, T. has rarely been surpassed. Napoleon admired him without limit. His character as a man is still more admirable. He was modest, simple, truthful, and full of genuine kindliness to all beneath him, especially to his war-worn veterans, to whom he liberally gave of his private resources. We have two publications of T., which possess a very great interest. The first, a narrative of his campaigns from 1643 to 1659, was published by Ramsay in his *Histoire de T.* (Par. 1735); the second is *Lettres et Mémoires du Maréchal de T.* (Par. 1782), edited by the Comte de Grimoard. T.'s 'Life' has been written by Pauletti (Par. 1677), de Courtilz (Koln 1685), Ramsay (Par. 1735), Raguenet (Par. 1738; new ed. 1877).

Tur'génjev, also **Tourguenef, Ivan Sergeïtch**, the most famous of Russian novelists, was born at Orel 20th October (November 9th) 1818, his family being of an old Boyar stock which in the last and present centuries produced several men of note in politics and literature. T.'s youth was passed in the country; but between the years 1834 and 1838 he studied at the universities of Moscow and St. Petersburg, and then spent two years at Berlin studying German philosophy, and acquiring the cosmopolitan literary knowledge which distinguishes him even among his widely educated compatriots. After a short trial of state service in the Ministry of the Interior, he devoted himself entirely to literature. His first attempts, written under the influence of Pushkin and Lermontoff, attracted no attention, but his series of *Sketches from a Sportsman's Journal*, published in 1846 in Belinski's review *Sowremennik* (*The Cotemporary*), aroused the greatest interest. They were for the most part directed against the institution of serfdom, but, apart from this tendency, exhibited all the characteristics which his later works have more fully developed—minute realism, unique power of dramatic presentation along with a striking lack of dramatic construction, deep insight into character, and delicate humour, thrown into relief by the sombre pessimism which forms the unvarying ground-tone of every picture which the author presents. Strangely enough, the first collected edition of these sketches (1852) escaped censure, but an article on the lately-deceased dramatist Gogol, which T. published about the same time, led to his banishment for two years to his estate. Released at the intercession of the Heir-Apparent, the present Emperor, he at once went abroad, and afterwards lived by turns in France, Germany, and Russia, until in 1863 he settled at Baden-Baden, where he now resides along with the Garcia-Viardot family. T. may be called a prolific novelist, though all his tales are short, none extending beyond a single volume, and some even of the most remarkable occupying only a few pages. The following is a list of his longer works:—*Rudin* (1855), *Helene*, *A Nest of Nobles* (1858), *Fathers and Sons* (1861), *Smoke* (1867), *An Unfortunate* (1868), *Spring Torrents*, *Virgin Soil*

(1876). Of his shorter stories, the following are among the most notable:—*Three Portraits* (1846), *Mumu* (1852), *A Correspondence* (1854), *Assja* (1857), *Apparitions* (1863), *The Adventure of Lieutenant Jergunoff* (1867), *The Jew, The Dog, Petouchkoff, The Brigadier, A King Lear of the Steppes, Punin and Balburin, Three Meetings, Faust, &c.* Most of his works have been translated into German and French, some of them being written in French by the author himself. The following have appeared in English:—The *Sketches from a Sportsman's Journal*, under the title of *Russian Life in the Interior*, translated from a bad French translation by Meiklejohn (Edinb. 1855); *Fathers and Sons*, translated by E. Schuyler (New York 1867); *Smoke* in a miserable translation, against which T. has protested, under the title of *Life at Baden-Baden* (Lond. 1868), and in an improved form (New York 1872); *A Nest of Nobles*, translated by Ralston under the title of *Liza* (Lond. 1869); *Helene*, translated by C. E. Turner, under the title of *On the Eve* (Lond. 1871); *Spring Floods*, translated by Mrs. Butts (New York 1874); and *Virgin Soil*, translated by T. S. Perry (New York 1877), and by Ashton Dilke (Lond. 1878). For biography and criticism, see *Der Salon*, vol. iii. (Leipzig 1869), Otto Glagau's *Die Russische Literatur u. Iwan T.* (Berl. 1872), *Scribner's Magazine* for June 1877, and Henry James, jr.'s, *French Poets and Novelists* (Lond. 1878).

Tur'got, Anne Robert Jacques, Baron de L'Aulne, a distinguished French economist and statesman, was born of a noble family at Paris, 10th May 1727. He was destined for the Church, and studied at various theological seminaries, and finally at the Sorbonne. Whilst a student here he wrote his first work on economics, *Lettre à l'Abbé de Cicé sur le Papier Monnaie* (7th April 1745). This treatise proved in a masterly manner, as against the economic fallacies of his time, 'that credit does not create capital, but only facilitates circulation.' In 1751 after ripe reflection he abandoned the clerical profession and entered the public service. In 1761 he was appointed Intendant of Limoges. During this interval of ten years (1751-61) he published the following works, *Lettres de Mme. de Grafigny* (1751), in which he criticised the pedantic system of education then in vogue, *Lettres sur la Tolerance* (1753), a noble plea in favour of religious liberty, *Valeurs et Monnaies* (1758), and shortly afterwards *Reflexions sur la Formation et la Distribution des Richesses*, in which he partially anticipated the riper speculations of Adam Smith. During this period also he enjoyed the intimate friendship of Quesnay and Vincent de Gournay, the eminent economists, and gradually matured his views on political and social subjects. The Limoges appointment gave him the opportunity of putting them into practice. He held the office for thirteen years, and during that time fought all sorts of abuses. He equalised and reduced taxation, removed imposts injurious to trade, and commuted *corvées*. His wise and liberal action reduced the burden of a terrible famine that desolated the country. He improved and encouraged agriculture. At last a wider field of usefulness was opened to him. On 20th July 1774 he was appointed Minister of Marine, and the same year placed over the department of finance. He had formed a vast scheme of financial, commercial, and political reform, and this he proceeded to put into execution. He restored free trade in corn and wine within France; he suppresed *corvées* and abolished *jurandes* or guilds; he reformed the finances; he encouraged the higher education and literature, and all in less than two years. But the vested interests of oppression and wrong, unjust exemption and unjust privileges, were too powerful to fall before the attacks of one man. As the result of a succession of intrigues he was dismissed from office (13th May 1776). The rest of his life was given to literature and science. He died 21st March 1781. The record of T.'s labours may be given in a Virgilian line, 'If Troy could have been defended, it would have been defended by this right hand.' Plans of reform like his were the only hope of salvation for France. If it had been possible to carry them out, the blessings of the Revolution might have been attained without its horrors. Personally T. was a man of a singularly pure and elevated character. His views were not merely in advance of his time, but in some respects of our own. He believed in free trade, 'even if other nations should set their ports against us.' He was an ardent advocate of freedom of thought and speech. Amidst infidels, hypocrites, and fanatics he alone preached and practised the maxims of a liberal piety. It is said of him that he leaped from the cradle to manhood, so precocious was his intellect. He worked continually. He wrote on many subjects, and always well. Like his great countryman, he was without fear, and his name is without reproach. See T.'s *Œuvres Complètes* (9 vols. Par. 1808-11; 2 vols. 1844); Condorcet's *Vie de T.* (Lond. 1786); Tissot's *T.* (Par. 1862); Professor Hodgson, *Two Lectures on T.* (Lond. 1870); J. Morley in *Fortnightly Review* (1870 and 1871); *Westminster Review*, vol. xvi.; and Foncin, *Essai sur le Ministère de T.* (Par. 1876).

Tu'rin (Ital. *Torino*), a city of N. Italy, formerly the capital of Piedmont and residence of the Dukes of Savoy, on the Po, which immediately below receives the Dora Riparia, 95 miles N.W. of Genoa by rail. Situated on an extensive plain, bounded W. by the Gratian and Cottian Alps, it is conspicuous among European cities for the regularity of its construction, its plan presenting an uninterrupted series of rectangular blocks and houses (*Isole*), and of long, broad, straight streets (formerly called *Contrade*, now *Vie*), interspersed with wide squares and delightful gardens. This notable symmetry is due to the circumstance that the plan of *Colonia Julia*, founded by Augustus, was carefully preserved in the extension of T., begun by the princes of Savoy in the 17th c. The fortifications raised by Francis I. in 1336 were partly cleared away during the siege of 1776, and later works were demolished by the French in 1801, while the citadel gave place to the railway in 1852. Opposite T., on the right side of the Po, which is here crossed by three bridges (one erected 1876-77), rises Monte dei Capuccini, 170 feet high, commanding a magnificent view The principal streets are the Via Roma, between the Piazzo Carlo Felice and Piazza Castello; the Via de Dora Grossa, between the Piazza Castello and Piazza della Statuto; and the Via di Po, going from the chief bridge, and built with arcades (*Portici*), which present a busy, brilliant appearance when lighted in the evening. Among the more important public works in recent years are the levelling of the Bastion Garden (*Giardino dei Ripari*); the conversion of the old Piazza d'Armi into building plots (1878), the transformation of the old Ghetto into an ornamental block of houses, and the construction of new river quays. T. is somewhat destitute of buildings of striking merit, as well as of antiquities. The Palazzo Madama, the lofty, cumbrous castle of the 13th c., is the only mediæval structure. Taking its present name from the mother of King Victor Amadeus II., who as Dowager-Duchess (*Madama Reale*) occupied and embellished the building, it was the seat of the Italian Senate till 1865, and now contains various institutions. The Palazzo Reale, a plain brick edifice of the 17th c., has a sumptuous interior, and a staircase adorned within recent years by statues by Vela and Varni. The Galleria Beaumont, or left wing, contains the Royal Armoury, one of the finest selections in Europe. Other buildings are the Palazzo Carignano (1680); the Italian Chamber of Deputies (1860-65); the Academia delle Scienze, containing a gallery of 514 pictures, and rich museums of natural history and antiquities (Egyptian); the cathedral of S. Giovanni Battista, rebuilt 1492-98, and containing tombs of the Dukes of Savoy; the richly-decorated Corpus Domini, restored in 1753; the Palazzo di Cetta (1659), with a portico adorned with statues, including one of Victor Emmanuele (1860); the Pinacotica, a royal picture-gallery recently formed, but containing among other treasures a valuable Memling; the Royal Library, with 50,000 vols. and 2000 MSS.; the Museo-Civico, with ethnological, prehistoric, and art collections; the large dome-church of Gran Madre di Dio (1818), in imitation of the Pantheon at Rome; and the Synagogue, the loftiest building in T., with a singular columnar façade, erected by Antonelli in 1863. The Superga (1718-31), now the burial-church of the House of Savoy, stands on a hill 2555 feet high, to the E. of T., and adjoining it are a seminary for priests and a trattoria. The university, founded in 1404, had, in 1875, 74 professors and 1292 students, and possesses a library of 225,000 vols., many valuable MSS. from Rabbis, and rare editions (Aldi). T. is peculiarly rich in statues, among the more notable of which are those of King Carlo Alberto and Emmanuele Philiberti, both by Marochetti: Brofferio, the poet and orator (erected 1871), d'Azeglio the patriot (1873), Cassini the jurist (1873), Cavour, by Dupré (1873), and Ferdinand of Genoa, by Balzico (1877). T. is a great centre of the N. Italian trade, and has, besides small industries in metal and wood, im-

portant manufactures of machinery and tools, tobacco, woollens, silks, cottons, leather, chemicals, gloves, Italian pastes, musical instruments, baskets, hats, and stearine candles. A single match factory employs 627 hands (470 females), and produces 7 million wooden and 4 million wax matches a day. A specialty is rabbit-breeding, begun only in 1873, already assuming great importance as a means of supplying the food market and the fur trade. T. has street tramways and is well lighted with gas. Pop. (1878) 227,843. T., originally a town of the Taurini, a Ligurian tribe, was sacked by Hannibal, B.C. 218, but became a Roman colony, B.C. 166, and was called *Augusta Taurinorum* by Augustus. It fell to the Lombards in A.D. 570, and by Karl the Great was made the residence of the Markgrafs of Susa, on the expiry of whose line it passed to the House of Savoy in 1060. It was taken by the French in 1506, and held till 1562; again taken in 1640 and in 1798, and on the last occasion held till 25th May 1799, when it was recovered by Suvoroi. After the battle of Marengo (1800) the French once more seized T., which remained in their hands till the Peace of Paris restored it to Sardinia in 1814. Long the centre of the national struggle for unity, it was the capital of Italy from 1859 till 1865, when it was superseded by Florence. See Cibrario's *Storia de Torino* (Tur. 1846).

Turkestan' (properly *Turkistan*, 'land of the Turks), the name of a wide, longitudinal, depressed region in Central Asia, which comprises the basins of the Amu-Darya (q. v.) and the Tarim (q. v.). It is separated on the S. by the Kuen-Lun from Tibet, by the Karakorum (Mustagh) and Hindu Kush from India and Ladak, the latter chain continuing W. in the mountains of Afghanistan and Persia. In the N. it is separated from Zungaria (q. v.) and the Russian province of Semipolatinsk by the Thian-Shan mountains. Divided by the Pamir Plateau (q. v.), or 'roof of the world,' into two distinct portions, T. has a total estimated area of 1,576,400 sq. miles. Eastern T. shades off into the Desert of Gobi, while Western T., sinking to the level of the Kirghis Steppes, extends to the shores of the Caspian. These two regions have a very dissimilar character, the latter containing the Iranian Khanates, now mainly embraced in the Russian Empire, the former from olden times, as now, the arena of Turkish adventurers, who have more or less successfully asserted their dominion against the Chinese Empire. Within *Western* T. are comprised the Russian government-general of T., the tributary khanates of Bokhara and Khiva, the Turcoman steppes, and the independent hill-districts of Karategin on the upper Oxus. The country is nearly synonymous with the basin of the Amu-Darya, and Russia holds both the right bank of the river in what used to be Khivan territory, and its delta, green with rice-fields. Not only is Khiva bound to receive traders from no other country than Russia, but ever since that power occupied Samarcand it has commanded the waters of the Zar-afshan, on which part of Bokhara (and especially its capital) depends for existence. The Amu valley and delta are covered with a grey clay, impermeable to water, and therefore invaluable to the inhabitants for the construction of canal-banks. The non-irrigated and far greater part of Western T., with the exception of a few table-lands, is covered with black or yellow sands (see KARA-KUM and KIZIL-KUM), and the only land fit for cultivation, in addition to the oases along the river, are the slopes of the hills. Khiva is the principal of the oases, and the Amu-Darya, at its greatest height in July, overflows the desert in the direction of the Caspian for 50 miles. By November 1874 the Russians had finished works at Khojend which were capable of irrigating 43,200 hectares. The climate is one of extremes, and the heat of autumn is aggravated by a wind laden with fine dust which is almost suffocating, and darkens the air for a week at a time. There is as yet little mining, although the Russian flotilla on the Aral draws supplies from the rich coal-deposits on the Sir-Darya, while the Thian-Shan and its spurs are particularly rich in iron, lead, rock-salt, and naphtha. Gold is found in the Obi district, and in the Karatan mountains are extensive coal-deposits, besides valuable ores. Wheat and clover are the winter crops; all other cereals, such as maize, millet, barley, rice, and pease, are sown in April and gathered in August. Grapes are cheaper than potatoes, and yield a good wine. Bokhara cotton is of excellent quality, and some 2,000,000 cwts. are despatched to Nijni-Novgorod, where 36 lbs. are sold at from 12 to 20 roubles. Tobacco and silk are also largely produced; some tobacco-seed from Maryland is succeeding admirably. Since the incorporation (1868) of T. with the Russian toll-dominion, trade statistics are wanting, but in 1867 the total Russian traffic with the country S. of the Kirghiz toll-line was valued at 29,300,000 roubles. Trade will receive a fresh impulse from the establishment of the railway from Orenburg, the survey for which was completed in December 1878. On a basis of a census of families the pop. is estimated at 4,000,000 Russian subjects, including Khokand; and 3,600,000 inhabitants of Bokhara, Khiva, Karategin, and the steppes. The chief races are Usbegs (q. v.), who are purely Turkish; Tajiks, the Iranian and trading people; the predatory Turcomans, Turks with an Iranian infusion, and the nomad Kirghis and Kara-Kalpacks. The prevalent language is akin to Turkish. *Eastern* T. is called *Nan-ly* by the Chinese, *Altai-shar* ('six towns') by adjoining Mohammedans, and *Iiti-shar* ('seven towns') by its Moslem rulers. It may be considered as identical with Kashgar (q. v.). Till 1853, Eastern T. was a Chinese province, but that year witnessed a massacre by the natives of the Chinese who rejected Islam, and subsequently it was ruled by its despot liberator, Yakoob Beg (q. v.), till his death in 1877. He was succeeded by his son, but the Chinese Government recovered its lost territory in 1879. See MacGahan's *Campaigning on the Oxus* (Lond. 1874); Hellwald's *Russians in Central Asia* (Lond. 1874); Schuyler's *T.* (6th ed. Lond. 1877); and Prejevalsky's *Through T. to the Lob-nor* (Lond. 1879).

Turk'ey (*Meleagris*), a genus of Rasorial birds, allied to the common fowl on the one hand, and to the pheasant and peacock on the other. The bill is strong, arched at its tip, and keeled. The nostrils are in a groove of the bill, and the wings, which are short, have their fifth and sixth quills longest. The tail is broad and rounded, and the tarsi are stoutly built, scaled in front, whilst they are also spurred. The front toes are united at the base. The head and neck are bare and provided with *wattles*. America is the native country of the T., the wild T. being found abundantly in certain districts of the United States. The Common T. (*Meleagris gallopavo*) is too well known to require any detailed description. It appears to have been first introduced into Europe at the beginning of the 16th c. The plumage of the wild male T. is a golden bronze, shot with violet and green, and banded with black. Its average length is 4 feet. The head is provided with wattles of bluish or purple colour, and a tuft of stiff black hairs protrudes from the breast. The Honduras T. (*M. ocellata*) is a different species from the true wild T., wanting the hairy tuft on the breast, and smaller than the common T. The back is of a bronze-green colour varied with gold, and the primary wing-feathers are black, edged with white. whilst the tail feathers are 'eyed.' The wattles and fleshy protuberance depending from the bill are orange-hued. The wild T. begins in October to migrate southwards to the Ohio and Mississippi.

Turkey-Buzz'ard. See VULTURE.

Turkey-Red' is the most brilliant and unalterable of all dyes applied to cotton or other vegetable fibres. The art of producing the colour is supposed to have been known in India from very remote times. In 1747 several Greek dyers were brought by a French firm to Rouen, and on account of its source the colour then came to be known as Adrianople Red, or T.-R. The art was not introduced into Great Britain till about 1783, in which year an enterprising manufacturer, David Dale, and an eminent practical chemist, Charles Macintosh, engaged a French dyer, M. Papillon, and laid the foundation of the great T.-R. industry which now flourishes in and near Glasgow. Papillon at a later period transferred his services to Lancashire. The industry is now also extensively prosecuted in Switzerland, Elsass, and various other German centres. The dye was originally applied to yarn alone, but since 1810 it has been the practice to dye piece-goods also. The material to be dyed—well bleached and washed—is treated with an emulsion of Gallipoli (olive) oil, potash, and water, and thereafter exposed to the air, or more generally hung in a heated stove for twenty-four hours. This operation is repeated several times according to the depth and intensity of the colour desired, and in the end the fatty material not fixed in the fibre is removed by steeping the cloth in a bath of carbonate of soda, and squeezing out the 'old white liquor,' as the fatty substance is termed. The goods are next 'sumached' with a solution of gall-nuts or sumach and alum, and they are then 'aged' by exposure in a hot stove for about three days. Thereafter they

are passed through a bath of hot water and chalk, and well washed, when they are ready for dyeing. Formerly madder was the dyeing material, but now artificial alizarine is almost exclusively employed, and produces magnificent effects. The pieces are kept in the dye beck in a solution at near boiling point for about three hours. Generally the processes from sumaching onwards are repeated a second time, and finally the dyed goods are cleared in three separate boilings, the first with soap, and the second and third with chloride of tin added to the soap solution. After drying, the operations are complete, the whole consuming about three weeks, although good effects may now be produced with fewer processes and less loss of time.

Turk'ish or **Ott'oman Em'pire** (Turk. *Osmanli-Vilayeti*), one of the largest and most populous states of the Old World, consisting of adjacent parts of South-eastern Europe, Western Asia, and Northern Africa. It occupies a remarkably central position, but its strength lies in Asia, where the Turk is supreme up to the Russian and Persian frontiers. In Africa, distance has co-operated with other causes in making Egypt and Tunis but loosely dependent on the Sultan's authority, but Tripoli and Barca are still actually Turkish pashalics. Important alterations have been effected in European Turkey by the provisions of the Treaty of Berlin (13th July 1878). The chief terms of the Treaty are (1) the erection of Bulgaria into an autonomous and Christian principality, tributary to the Sultan; (2) the formation of Eastern Rumelia as a semi-independent Christian province (see RUMILI); (3) the complete liberation of Servia, Rumania, and Montenegro from Turkish allegiance; (4) the occupation and administration of Bosnia and Herzegovina by Austro-Hungary; and (5) the recommendation by the Powers of a rectification of the Greek frontier, and an offer to mediate if necessary. Large territorial cessions have accompanied these political changes, the aggregate amount of area detached in European Turkey alone being 70,617 sq. miles, and carrying with it 4,425,000 inhabitants. Not to mention the retrocession of part of Bessarabia by Russia (see RUMANIA), other important changes are the cession of the Armenian districts (Ardahan, Kars, and Batoum) to Russia in accordance with the Treaty, and the occupation of Cyprus (area, 2288 sq. miles; pop. 150,000) by England in terms of the Anglo-Turkish Convention of 9th June 1878. Prior to these changes, European Turkey, exclusive of Rumania, had an area of 142,751 sq. miles, and a pop. of 9,700,000. The area and population of 'consolidated' Turkey are as follows, according to the *Almanach de Gotha* for 1879:—

	Area in sq. miles.	Pop. 1879.
Turkey in Europe	72,134	5,275,000
" Asia	729,684	17,536,465
" Africa—		
Egypt and Dependencies . . .	869,378	17,400,000
Tripoli	344,430	1,010,000
Tunis	45,715	2,100,000
Total	2,061,341	43,321,465

Reckoning as still part of Turkish territory the provinces of Bulgaria and Eastern Rumelia and those presently occupied by Austria, the European portion has an area of 140,965 sq. miles and a pop. of 8,971,000. By the San Stefano Treaty, Turkey was called upon to surrender 78,550 sq. miles and 4,539,000 inhabitants—a demand relatively greater than that of the Berlin Treaty. According to the former, Bulgaria was made to extend from the Danube to the Ægean (65,560 sq. miles; pop. 3,986,000), while the latter drew the boundary at the Balkans. The territory which passed out of the possession of Turkey is shown in detail in the following table:—

	Sq. miles.	Population.	Mohammedans.
Ceded to Rumania	5,935	246,000	142,000
" Russia	5,265	127,000	...
" Servia	4,284	367,000	75,000
" Montenegro . . .	1.976	116,000	9,000
Formed into the Principality of Bulgaria	24,659	1,859,000	681,500
" Province of Eastern Rumelia	13,664	751,000	265,000
To be administered by Austria	20,117	1,086,000	513,000

The portion of Turkey governed directly is divided for administrative purposes into *vilayets* or governments, into *sandjaks* or districts, and into two still smaller subdivisions. *European Turkey* comprised, prior to the Berlin Treaty, nearly the whole Balkan peninsula, extending from the frontier of Russia and Hungary to that of Greece. It is now practically bounded N. by the Balkans, and its northern boundary-line is continued along the frontier of Servia and Montenegro, the provinces of Bosnia and Herzegovina which form an outlying portion in the N.W. being separated from the Adriatic by the coast-strip of Dalmatia. It is now divided into the vilayets of Constantinople, Adrianople, Gallipoli, Saloniki, Janina, Bitolia (Monastir), and Scutari. The Island of Crete (q. v.) forms a separate vilayet, and among the islands that fall under European jurisdiction are Samothrace, Imbros, and Lemnos, near the Dardanelles. *Asiatic Turkey* comprises Asia Minor eastward to the Persian frontier, and to the S., Mesopotamia, Syria, the whole Red Sea coast of Arabia, and the northern half of the Arabian coast on the Persian Gulf. Besides the nine vilayets forming Anatolia, the vilayets into which Asiatic Turkey is divided are Erzerum, Diarbekr, Bagdad, Aleppo, Syria, Hedjas, Yemen, and Hedjen. The Ægean coast has a fringe of islands, of which the principal are Rhodes, Cos, Patmos, Chios, Mitylene, and Tenedos. (For the geography see ANATOLIA, SYRIA, PALESTINE, ARABIA, &c., and articles on the various physical features, as TIGRIS, EUPHRATES, LAKE VAN, LEBANON, &c.). The only very considerable town in Turkey is Constantinople (q. v.), the capital of the empire.

Physical Aspect.—European Turkey is for the most part mountainous, but with richly varied scenery; its fertility is boundless, and its climate, as a whole, is genial and healthy. Limited in area, it still embraces some of the fairest parts of Europe. Alpine continuations run along the Dalmatian land-frontier, where they are called the Dinaric Alps, and further S. they spread out over the whole Greek peninsula in multitudinous ridges. The best defined of all the ranges is the Balkan (q. v.), which, running E. and W., separates the basin of the lower Danube from the country draining to the Archipelago, and terminates on the Black Sea in a bold promontory. At Rilo-Dagh, which has a height of 9842 feet, the Balkan sends off the Despoto-Dagh in a southerly direction to the Archipelago, parting the basins of the Struma and Maritza. Further W., the main southerly continuation of the Dinaric Alps, the Pindus range traverses Albania, attaining in the N. in Tchar-Dagh its greatest height of 9700 feet. Near the Greek frontier Pindus sends off a branch towards the Gulf of Saloniki, and this branch terminates in the Olympus of Greek poetry. The Tchar-Dagh is the central point in the configuration as the source of streams flowing in different directions, the Morava to the Danube, the Vardar to the Archipelago, and the Drin to the Adriatic. The Balkan owes much importance to its position as a defence of Constantinople, and it is crossed by three principal passes from Bulgaria,—the one from Sophia to Philippopolis on the upper Maritza, called Trajan's Gate; the second, leading down the Tunja to Adrianople, and guarded by the fortress of Shumla; the third, the Shipka Pass, between Kesanlik and Kabrova on the way from Tirnova. In this mountainous country plains are not wanting, the largest being the basin of the Salambria in Thessaly, the joint basins of the Vardar and Struma in Macedonia, and the drainage area of the Maritza in Thrace. These are insignificant compared with the plain of the lower Danube, and its northern affluents the Sereth and Pruth. Excepting the Danube, the rivers of the peninsula are practically useless for navigation, being of the nature of torrents. The largest, the Maritza, admits rafts as far as Adrianople, but only in winter. Amid the rugged fastnesses of Albania (the native *Skiperi*, or 'land of rocks') are numerous mountain-lakes, adding their charm to the magnificent scenery. The chief of these lakes, which drain into the Adriatic, are Scutari, with its affluents the Bayana, the Ochrida, drained by the Drin and the Janina, at the S. end of which is believed to have stood Dodona, the seat of the most famous oracle of Zeus.

Climate, Geology, and Products.—In European Turkey the general healthiness of the climate contrasts strongly with the pestilential state of the lower Danube during summer. Only near the fetid sea-marshes scattered at intervals along the shore is fever prevalent, but disease finds a powerful ally in the sanitary neglect universal in the larger towns. High up the mountains the winter is singularly severe, the higher summits bearing perpetual snow. But where the land declines towards the

Archipelago on the Adriatic the climate is, generally speaking, that of southern Europe—mild winters alternating with hot summers. Earthquakes are not unfrequent in Albania, where Secondary rocks predominate (chiefly crystalline slate). In the S.W. of Albania, and also in the basin of the Maritza, the formation is Tertiary. The Balkan is mainly Cretaceous, and contains at least one track of Upper Palæozoic, a small portion of which also appears to the N.W. of Constantinople. Hot springs are numerous. The crystalline schists are richly metalliferous, but there is almost no mining industry. Iron, lead, and copper abound, and among other minerals present are gold, silver, coal, sulphur, salt, alum, and marble. The pine, beech, ash, and oak, which cover great portions of Bulgaria and Rumania, are confined in the S. to the mountain-sides, which they clothe to high elevations. The oak yields for export galls and *valonia* (*i.e.*, acorn-cups), invaluable for tanning. On the lower mountain-slopes grow walnuts, mulberries, planes, maples, carobs, almonds, sycamores, &c. The fruits include the apple, pear, cherry, plum, apricot, peach, citron, olive, and vine. To the S. of the 40th parallel the commonest fruit-tree is the olive, while tobacco, silk, and cotton are staples. From the plum is manufactured the *raki*, or common spirit of the country. The soil is very fertile, but only a comparatively small portion of the area is under culture. Besides wheat, barley, and rye, the crops include buckwheat, maize, rice, hemp, flax, saffron, aniseseed, cummin, and liquorice. The S. base of the Balkan is remarkable for the culture of roses for the manufacture of the costly attar. Throughout Turkey the peasantry give much attention to live-stock, and cattle, horses, sheep, and swine are among the commonest articles of trade.

Industries, Customs, and Classes.—While the Bulgarians, sober, diligent, and slow of speech, find their sole interest in agriculture, the Greeks, enterprising in the cultivation of any special kind of produce, are versatile and ubiquitous, and in all vocations they exhibit energy, perseverance, and address. The Albanians, in addition to agriculture, are employed in making a stout woollen felt for the *capa* or cloak, a kind of red leather, and home-spun tissues used for the rich embroideries of the national costume. Their social relations are limited to two ideas, namely, *bessa* ('peace') and the implacable *vendetta*. 'An Albanian's gun is his companion and his means of subsistence in peace and war.' The penniless *chiplak*, when he takes to brigandage, retains the qualities of bravery and gratitude, and accounts it dishonourable or unlucky to attack women. The Turkish peasant is industrious, ignorant, and submissive, and the more regular enforcement of the conscription has developed his proneness to apathy and improvidence. The tradespeople of the towns are ranged in *ensafs* or guilds, and some of these corporations admit Christians of the same occupations, but the prosperity of the Christian excites a bitter feeling among his Turkish neighbours. Commercial enterprise is almost unknown among the wealthier Turks, and this is due in part to individual lethargy, in part to the attitude of the Government, which has never shown readiness to aid private undertakings, or to offer the guarantee of disinterested protection. The Government now professes to share the anti-slavery ideas of England, but on female slavery is based the system of the harem and seraglio. According to the patriarchal custom, the slaves are considered part of the household; Circassians are often advanced to the dignity of wives. Abyssinians are the most capable, and negroes the most numerous. A slave is entitled to her liberty after seven years of bondage, and the condition is usually observed, and she is then dowered and married to a freeman. Polygamy is practised agreeably to the Koran, and the Asiatic element appears markedly in the domestic arrangements, in spite of the recent adoption of European customs and fashions and the enforcement of a modified Frankish dress upon Government servants. The women are secluded in the *haremlik*, and their education is limited to frivolous accomplishments and the arts of the coquette. A real *Hanoum* or Turkish lady is dignified, elegant, sensible, and often naturally eloquent, although not gifted with great conversational resources. The bath is an appendage of even the poorest house, and some of the public baths are often fine buildings.

Land Tenure.—Land is of three kinds: *mevkoufé* (or *vakouf*), 'church' property; *mirié*, crown property; and *mulk* or *memlouké*, freehold. The first is land set aside for the support of religious establishments, the mosques, *medresses* or mosque colleges, other religious schools, and *imarets* for almsgiving. On the conquest, a large share of land was held 'for God,' and this has been greatly augmented by private munificence. But such land is acquired from a third source. Being held direct of Allah it is free of taxation, and a proprietor by selling his land to a mosque, for say a tenth of its value, and retaining the right of lease, not only gets rid of all taxes, but is safe from confiscation by government, extortion from its officials, and persecution from private creditors. He may sell the lease, or at his death it passes to his heirs, but in default of direct heirs the lease reverts to the mosque. So avaricious are the mosque authorities that they willingly contract with Christians. These lands are estimated at two-thirds of all of Turkey (see RELIGION). The *mirié* include the private demesnes of the Sultan, lands reserved for the partial support of the administration, and the waste lands. They formerly included till the time of Mahmoud II. an enormous area granted by the Sultan on condition of military service. Great abuses are occasioned by the corruption of the *Tapou Memours* or *mirié* inspectors, appointed in 1871. The *memlouké* or freehold lands are very limited, a prejudice existing against this form of tenure on account of the difficulties of establishing titles. The division of property among all the children, and the reduction of its value by succession duties, tend to the deterioration of Turkish estates, and lead generally to mortgage at an average interest of 18 per cent. Large estates can be purchased for small sums, and wealthy native Christians would gladly become purchasers but for the risks of insecure tenure and agrarian violence. Foreign subjects now hold land on the same conditions as the subjects of the Porte, and they are greatly more respected than native Christians. Some English gentlemen possessing farms in Macedonia had no cause of complaint even during the anarchy of 1877.

Commerce and Public Works.—No official returns of the trade are published, but the exports of the empire, excluding Egypt and Rumania, has been estimated at £10,000,000, and the imports at £18,500,000. The imports are almost entirely manufactured goods, and the exports include grain, tobacco, wool, silks, carpets, morocco leather, opium, meerschaum, attar of roses, cotton (since 1860), drugs, dye-stuffs, spices, and fruits. The exports from Great Britain in the year ending 31st December 1878 to European Turkey amounted to £4,167,232, and to Asiatic Turkey, including Cyprus, to £3,591,778. In 1877 the corn exports to Britain alone amounted to £2,641,226. The chief ports after Constantinople are Smyrna, Beyrout, Saloniki, Volo, and Adana. In 1877 there entered at all the ports 205,626 vessels of 19,621,611 tons (226,540 vessels of 18,855,488 tons in 1876). In 1877 the Turkish mercantile marine had a total tonnage of 181,500, including 226 deep-sea vessels of 345,000 tons, and 11 steamers of 3350 tons. The great obstacles to trade are the want of internal communications, the maladministration of the customs, and the ignorance and peculation of officials. (See *Report of the Incorporated Chamber of Commerce of Liverpool*, 1879.) In 1877, besides the railway from Constantinople to Sophia, with its two branches, Turkey had a line from Saloniki to Mitrovitza, and when extended this line will connect Macedonia with Austro-Hungary. The total length of railway open in 1878 was 786 miles. There are also lines from Smyrna to Aidin (145 miles), and from Ismid to Scutari (27 miles). An important item in the scheme of reform in Asiatic Turkey is the project of a Euphrates Valley Railway.

Government and Administration.—The government is known in history as a despotism, tempered by the ecclesiastical authority of the Sheik-ul-Islam, chief of the Ulema, whose *fetva* or sentence, in reality the foregone conclusion of the nation or a dominant faction, passes for the will of God, and has availed even to the deposition of the Sultan. By way of answer to the remonstrances of Europe, a constitution on the French model was established, 23d December 1876. The Sultan or Padishah is declared irresponsible, but retains many of the chief functions of the State. The Grand Vizier is now called President of the Council of State; the Sheik-ul-Islam, or Grand Mufti, who represents the spiritual power of the Khalifat directly, is supreme judge. During 1878 there were six changes of ministry. The Ulema, the learned and rigid expounders of the Koran, have gained great ascendancy in public affairs. They are powerful advocates of 'reform,' but the reforms they demand are those of the ancient Osmanlis, and the execution of the Sheriat or Koran laws. The governors-general of vilayets

are called *Valis*; large districts are under *Mutessarifs*, or sub-governors. *Mudirs* are governors of villages, the inferior officials of which are *mukhtar*. These posts, formerly given to *Chibouk jes* (pipe-bearers), &c., are now filled by the sons of higher-class Turks trained at the *Kalem* or Chancellerie d'État. But the vast body of officials are as yet ignorant and unscrupulous. The municipal administration exaggerates, if possible, all the defects of Imperial rule. The sanitary laws were recently reorganised, and a district police corps was formed at an expense that might have ensured efficiency; but the towns are as neglected as ever; the ill-paved streets, badly lit with petroleum, are a receptacle for refuse. The country, since the war, is once more under the terror of brigandage. Robbery and violence are, however, the natural fruits of favouritism and bribery.

Finance, Army, and Navy.—The finances of T. are in a state of hopeless confusion, and the official budget is quite unreliable. The budget for 1877-78 gave the revenue at £17,752,810, and the expenditure at £28,578,640, leaving a deficit of £10,825,830, but the deficit for the year is estimated at not more than £4,250,214 by the *Bulletin de Statistique*. The floating debt amounts to £28,779,227. The supplementary budget to cover the war expenses is £14,609,506, and to meet this a new obligatory loan of £5,000,000 has been decreed in the interior, bearing 10 per cent. interest, the tax on sheep increased from £1,590,300 in 1876 to £2,925,000, and a foreign loan contracted with the holders of the bonds of 1854, 1855, and 1871, for a sum equal to and secured by the Egyptian tribute (£280,000). Gold is scarce, and the issue of paper-money (caimés) is enormous—£19,000,000 at the end of October 1878. At the beginning of 1878 the total general debt might be estimated at £245,200,000, comprising the consolidated debt, £200,000,000; applied arrears, £25,600,000; floating debt to bankers, speculators, &c., and paper-money, £19,600,000. By a law of 1869 military service is obligatory for all Mohammedans. The service is for twenty years, of which four (in the cavalry five) are in the active army (*Nizam*), two on leave (*Ikhtyat*), six in the landwehr (*Rédif*), and ten in the landsturm (*Mustahfiz*). The non-Mohammedans are exempted from service, and must pay a *Bedel-i-askeriyèh* of from £27 to £45 a-head; they are obliged, however, to serve in the fleet when called. The reorganised forces were 730,000 men till the end of 1878, and then the active army was reduced to 220,000 men. The artillery in the active army consists of 103 batteries with 618 guns. A considerable proportion of the better-class Turks belong to the army, but there is little chance of promotion on the mere strength of ability. The training of the new military schools is below the European standard. In 1878 the navy comprised 15 ironclads, 18 smaller ironclads (including 11 monitors), and 40 steamers. Vast sums have been lavished on ironclads, mostly of English make, but neither commanders nor crews seem expert in naval tactics.

Religion and Education.—According to E. G. Ravenstein (*Journal of Statistical Society*, September 1877), there were in European Turkey 4,247,000 Mohammedans, in Asiatic Turkey 12,273,350. In the former there were 4,705,450 orthodox Christians, 426,000 Latins, 89,000 Armenians, &c. The religion of the Turks is properly the orthodox or *Sunni* form of Islam, and the church is governed by the Ulema, or learned men trained in the mosques, between whom and the dervishes, who head the popular faith, there is the intensest rivalry. Softas, the supporters of the Ulema, may be called Mohammedan undergraduates. The Ulema order is divided into three classes; the *imams*, or ministers of religion; the *muftis*, or doctors of law; and the *kadis* or *mollahs*, judges. The first of these pronounce the prayers in the mosques and figure in social ceremonies; the second are barristers in the courts of justice; the kadis or judges are distinguished even in T. for avarice and venality. The enormous revenues of the vakouf or mosque lands, or what of the revenues are not embezzled, go to maintain the large class of Ulema. The Greek Church (q. v.) in T. is entangled to some extent with the Porte, but it is a sign of hopefulness that her ecclesiastics are finding their way to the colleges of Italy and Germany. The good resulting from the adoption of this creed by the Bulgarians has been sadly diminished by the long and bitter antagonism into which their Panslavism brought them with the Panhellenic Greeks. Only part of their grievance was amended by the substitution at a late date of a Bulgarian Exarch for a Greek Patriarch (see Lord Strangford's writings). Of recent years excellent religious books have been circulated by the Mechitarist College of Venice, and by the American missionary societies. These are specially acceptable to the Armenians. In Central T. alone there are now 26 organised Protestant churches, with some 2500 members. The present century has seen the introduction of Government schools. The international Lyceum at Constantinople was founded in 1868. Here the Bulgarians have always held the first rank; the Greeks, 'in addition to some good characters, have presented a great many bad ones.' (See *Revue des Deux Mondes*, October 15, 1874.) This result is in consonance with the more forward state of education in Bulgaria. There is now a celebrated Prussian school at Smyrna.

Ethnology.—The population of Turkey from the Adriatic to the Euphrates is singularly complex, distinctions of race being here intensified and there disguised by conditions of religion and language. Unlike the races of Western Europe, with their common Aryan descent and Christian faith, those of Turkey show no power of assimilation, but remain distinct as when they settled, unaffected by any predominating national type. 'We cannot conceive a Welsh, an English, and a Norman village side by side; but a Greek, a Bulgarian, and a Turkish village is a thing which may be seen in many parts of Thrace' (Freeman). The three races occupying the peninsula at the beginning of history are still there; the Greeks, distinguished by Greek speech and Orthodox faith; the Skipetar or Albanians, believed to represent the ancient Illyrians, and now intermingled with the Greeks, and the Vlacks and Rumans, in whom Freeman sees not the descendants of Trajan's Roman colonists, but Romanised Thracians. On these abiding races came, after the Roman Conquest, the Wandering of the Nations and the appearance of the Slavs, who in the time and manner of their coming answer roughly to the Teutons in Western Europe. The Slavs are undoubtedly the greatest elements in the peninsula, the Bulgarian Slavs prevailing in Macedonia as well as in Bulgaria, and the Servian Slavs prevailing not only in Servia but Herzegovina and Montenegro. In Western Europe the Turanian has repeatedly appeared, but only as a passing invader; his part was widely different in Eastern Europe. Avars, Patzinaks, Chazars, Cumans, and others, held temporary dominion, and three bodies of more abiding settlers, the Bulgarians, Magyars, and Mogul conquerors of Russia, entered from the N., while from the E. came a fourth, the Ottoman Turks. The Finnish Bulgarian has been absorbed among Slavonic subjects, and is a Slav bearing the Bulgarian name. But this is the only case of assimilation among the intruders. In the N., the geographical function of the Magyar has been to keep apart two great groups of Slavonic nations. The line of the Save and the Danube, so important in diplomacy, has no ethnological existence. In one part of Dacia the Teutonic element is represented in a pure form by the Saxon immigrants of Transylvania. The Turks, Osmanli, and Tartars constitute a majority of the population in only a few small districts, chiefly in Thrace and Eastern Bulgaria. They do not form a majority even of the Mohammedan population, which has been swelled by converts from all the subjugated races, except the Rumanians. Of the Christian races the Greeks are the cleverest, the Albanians the most heroic, and the Slavs the most peaceful and industrious. The permanence of Turkish rule has been in great part due to the disunion and jealousy of these races. The latest settlement in Turkey took place in 1864, when the Circassians, driven from home by Russian aggression, were allowed to spread over the Dobrudcha and Bulgaria. According to Ravenstein, the Turks in European Turkey in 1877 numbered 1,767,500, the Greeks 1,465,000, Albanians 1,920,000, Rumanians 189,200, Bulgarians 2,578,550, Servians 1,272,000, Russians and other Europeans 48,500, Armenians 112,200, Gypsies 104,750, Jews 78,800, Circassians 98,000, Arabs 27,500, Kurds 1000, and Lasis, &c. 1000. In Asiatic Turkey the Turks and Tartars numbered 6,983,500; the chief European race was the Greek (1,046,868).

History.—The generic name of Turk is now commonly given to the Ottoman, who in reality only represents one branch of the widely spread Turkish family (see TURKS). Care must be taken to distinguish the Ottomans from other Turkish dynasties, and also from the Saracens, with whom they first came into contact at the supremest period of the Khalifate (about 710), and from whom they took their religion. Much as the Franks set up 'a new Western Empire with its seat at the old Rome,' so the Turks, first the slaves and mercenaries of the Khalifs, ended by themselves claiming in the house of Othman the powers of

the Khalifate. The House of Seljuk (q. v.) and the Sultans of Roum or Rome (land taken from the Roman empire) had carried conquest to the shores of the Propontis before the Ottomans appear as unexpected allies of the latter against the Mongols. These Turks were seeking a settlement under their leader Ertoghrul, and for their aid they received a grant of lands. Othman (q. v.), or Osman, son of Ertoghrul, from whom is derived the national name of Osmanli or Ottoman, became the most powerful emir in Western Asia, and extended his dominion at the expense alike of Turks and Greeks. Just before his death (1326) his armies took Brusa, which became the Asiatic capital of the Ottomans. With Othman's son Orkhan the empire really begins, for he it was who threw off the allegiance to the Seljuk Sultan at Ikonion, extended the Ottoman rule over Anadol or Anatolia, the land of the East, and first made good a footing in Europe. To Orkhan is also due the institution of the tribute of children, on which was based the formidable force of the Janissaries (q. v.). The Ottomans had appeared in Europe as ravagers, as imperial mercenaries, and as allies of contending parties in the Empire, before they permanently occupied Kallipolis in 1356, but in the reign of Amurath (q. v.) they made swift advances. They formed Kallipolis into a compact power, hemmed in what was left of the Empire, and made Hadrianople their capital (1361). Servia had lost Stephen Dushan, and Bulgaria was then split into three kingdoms, and both powers were gradually dissolving, but Bosnia, which lay further from the Turks, was growing in strength, and a great Slav confederation under the Bosnian king Stephen resisted for a time the approach of the Eastern conquerors, only to be utterly crushed at Kossova in 1389. Amurath fell by the hand of an assassin, but Bajazet (q. v.) completed the conquest of most of Bulgaria, ravaged Bosnia, and made Servia and Wallachia tributary. Bajazet, the Thunderbolt, who exchanged the title of Emir for that of Sultan, was the first directly to attack Constantinople, but he had to turn aside in his own defence. Already had he overthrown a large army of crusaders under Sigismund of Hungary at Nicopolis (1396), and in turn he was defeated and taken captive by Timur at Angora in 1402. His possessions were disputed among his three sons, and the dispute ended in favour of Mohammed I., whose son Amurath II. (q. v.) wrested Thessalonica from the Venetians, and asserted the power of Turkish arms at Varna (1444) against Vladislaus and the great captain Hunnyades (q. v.). For Mohammed II. (q. v.), the Conqueror, was reserved the crowning triumphs of Ottoman power, the taking of the Imperial city and the overthrow of Greek nationality. 'We may take him,' says Freeman, 'as the ideal of his race, the embodiment in their fullest form of Ottoman greatness and Ottoman wickedness.' A general and statesman of the highest order, he prominently exhibits the peculiarly Ottoman vices of 'cruelty, lust, and faithlessness.' The annexation of Servia (1459) and Bosnia (1465), and the subjugation (1459) of Albania, long defended by Scanderbeg (q. v.), gave to European Turkey its well-known historical dimensions. The few islands or pieces of the coast that had escaped were held by Venice or other Frankish powers. Only the brave men of Zeta (see MONTENEGRO) and the city of Ragusa maintained their independence. In his last years Mohammed, having failed to take Rhodes from the Knights of St. John, suddenly seized Otranto, and but for his death the Ottoman power might have overshadowed Italy. Bajazet II., sensual and mystic, was deposed (1520) in favour of Selim I. (q. v.), the Inflexible, who added Syria and Egypt to the dominions, and to the secular title of Sultan the spiritual authority of the Khalifate. Selim outdid any previous Ottoman ruler in systematic bloodthirstiness, and was only hindered by the Mufti Djemali from a general massacre of the Christians. In the reign of Suleiman (q. v.) the Magnificent, the Lawgiver, the Ottomans were raised to their highest pitch of power and splendour; in it also began the decay of their military and moral supremacy. Suleiman took Rhodes and Belgrade (1521), and after the victory of Mohacz (1526) brought Transylvania into vassalage, laid siege to Vienna (1529), and transformed great part of Hungary into the pashalic of Buda. The Protestants of Hungary were certainly glad of the alliance, but only because of the fierce persecution of the bigoted Austrian kings. Wallachia and Moldavia were made tributary, while they retained the right of self-government, a system which lasted from 1536 to 1711, when the Sultans took to appointing as rulers Fanariot Greeks. Within Turkey the influence of the viziers, the pashas, and the women increased; the taxes were farmed out to Jews and Greeks, the soldiers fought less for victory than plunder. Luxury, idleness, avarice, and their kindred evils, followed in the train of conquest, and rendered this, in the opinion alike of Turkish and Christian writers, the period from which to date the decline of Ottoman power. The last of the line of great sultans was followed by Selim II., the Drunkard, whose short reign (1566–74) is marked by the first great Turkish reverse, the overthrow of the fleet at Lepanto (1571) by the fleets of Spain and Venice. The gain of Cyprus was far outbalanced by the loss of prestige which makes Lepanto a turning-point in Turkish history. From this period the names of sultans are but loosely associated by the European reader with the course of events. Among those distinguished by any peculiar quality, Amurath IV. (1623–40) stands forth as the most bloody, Ibrahim as the most brutally sensual of the line. Suleiman II. (1687–91) and Mustafa II. (1695–1703) were marked by some force of character. In the latter part of the 16th c., and most of the 17th c., the chief wars were with Venice, and with the Emperors as Kings of Hungary. Amurath III. was able to force the Poles, whose kingdom then stretched much further S.E. than ever before or after, to accept as king Stephen Bathori, Waiwode of Transylvania. In Hungary the Turk at first maintained his predominance, penetrating to within 40 miles of Vienna, but the great battle of St. Gothard (1664), in which Montecuculi defeated the Vizier Kiuprili, was the first of a long series of Christian victories. Notable also was the taking of Crete in 1669, after a siege begun in 1645, and the gallant defence of the town of Candia by the Venetians. Meanwhile the affairs of the Cossacks in the border-lands of the Crimea led to wars with Poland and Russia. In the Polish war (1672–76) Sobieski won several brilliant victories, and the Turks took the strong town of Kaminiec and the whole province of Podolia. This accession of territory, the last fresh conquest from a Christian power, was due to the ability of Kiuprili, the first of a family in which the office of Vizier was held at various times with singular power and tolerance. Kiuprili's successor, under Mohammed IV., Kara Mustafa, conducted the unsuccessful war with Russia, the first of any moment, in which he lost the superiority of the Ukraine. He undertook the complete conquest of Hungary, and again besieged Vienna (1683), but the city was saved by Sobieski, and by the end of the war (1698), in which both Sobieski and Eugene (q. v.) of Savoy won famous victories, Hungary was freed from the presence of the Turks. The Venetians had made good their chance to overrun the Peloponnesos, and Peter the Great had seized upon Azov, the key of the Euxine (1696). By the Peace of Carlowitz (1699), Mustafa II. surrendered not only Hungary (except the Banat of Temesvar, with Transylvania and part of Slavonia), but gave back Podolia to Poland and concluded a truce for twenty-five years. War with Russia broke out in 1711, and Turkey won back Azov, a success followed by the re-conquest of the Peloponnesos in 1715. The Turks proceeded to threaten Corfu and Dalmatia, but in 1716 the Emperor Karl VI. made an alliance with Venice, and the imperial armies under Prince Eugene subdued the remaining parts of Hungary and Slavonia, with Belgrade, and parts of Servia, Bosnia, and Wallachia, which were secured to the House of Austria by the Peace of Passarowitz (q. v.) in 1718. War again began on the part of Russia in 1735, and of Austria in 1737. The Russians made conquests which they failed to keep; the Emperor Karl, who had no longer a general like Eugene, was forced by the Peace of Belgrade (1739) to abandon all that had been won in Servia, Bosnia, and Wallachia. By the war waged in the last years of the Emperor Joseph II. various conquests were made, including Belgrade, but nearly all was given back by Leopold II. at the Peace of Sistova in 1791. Thus the last of the Austrian wars, which had gone on with breaks ever since the battle of Mohacz, ended in the freedom of Hungary being acknowledged, while Turkey was left in possession of Servia and Bosnia. With Catharine II. began the real advance of Russia. The first war of her reign began in 1768, and ended with the famous Treaty of Kainardji in 1774. Russia gained the disputed possession of Azov, and the Tartars of Crim were recognised as independent only to be incorporated by Russia in 1783. Moreover, Russia was acknowledged by the treaty as the protector of the Christian subjects of Turkey. By the Austro-Russian war of 1787–91, which ended in the Peace of Sistova, Russia advanced her frontier to the Dniester and obtained the famous fortress of Oczakov. Turkey was then in a state of

anarchy; the Sultan Selim III. was in the hands of the military chiefs, the leaders of the rebel Janissaries. Before the revolt of Servia began, the revolutionary French, under Bonaparte, attacked Egypt in 1798, and was only checked by a Turkish alliance with England and Russia. In 1805 Russia demanded a more distinct recognition of her protectorate over the Christians, but Selim, encouraged by Napoleon, resisted, and began to interfere, contrary to treaty, with the government of Rumania, thereby bringing on a war with England and Russia. Subsequently Napoleon and the Czar Alexander planned a partition of Turkey which came to nought; but the Russian war went on till 1812, when the Peace of Bucharest gave her Bessarabia (q. v.), with the Pruth as a boundary. Selim was deposed in 1807, and soon after murdered, as was also Mustafa, who was succeeded by the fierce Mahmoud II., under whom Servia (q. v.) won freedom in 1826, to be followed by Greece (q. v.), aided by the English, Russians, and French in 1829. The mock-reforms of Mahmoud, while they did little good to the Christians, stirred up the Mohammedans to revolt in Bosnia, Albania, and other parts. Egypt threw off the authority of the Porte, and seized Crete and Syria (see MEHEMET ALI), but England procured the return of the latter territory. The quarrel induced by Louis Napoleon between the Latins and the Orthodox, about the Holy Places at Jerusalem, led directly to the Crimean War. The Czar Nicholas again demanded a fuller acknowledgment of his rights as protector of the Orthodox, and on a refusal occupied the Principalities. Abdul-Medjid then declared war, and received the aid of France, England, and Sardinia. The English declaration speaks of the Sultan as 'an ally whose dignity and independence are assailed,' and 'the integrity and independence of whose empire has been recognised as essential to the peace of Europe.' (See OMAR PASHA, SEBASTOPOL, INKERMANN, BALAKLAVA, &c.) The Treaty of Paris (1856) declared that the Porte was admitted to the advantages of public law and the European concert, and engaged the Powers to respect 'the independence and territorial integrity' of the empire. Since 1856 there have been several revolts of the subject nations, notably in Crete (1866–68), and, greatest of all, in Herzegovina and Bosnia in 1875. The last outbreak stirred up the Bulgarians, already inflamed by the excesses of the Circassians, but the Turks met with little opposition in reducing the country by deliberate massacre. The Andrassy Note of 1875, to which the Powers assented, was a mere protest against the action of the Porte. In May 1876 the Berlin Memorandum was drawn up, proposing that the Christians should be allowed arms and that Turkish troops should be concentrated in certain places; but to this Lord Derby refused his assent. In December the Conference of the six Great Powers met at Constantinople. The reforms proposed did not even receive the nominal assent of the Porte, and no guarantee could be given for the working of the constitution projected by Midhat Pasha. During subsequent negotiations, England, by following a policy of resistance not to be ultimately supported by force, was compelled to make many unpalatable concessions. For an outline of the later diplomatic history and of the Russo-Turkish War, see RUSSIA. The principal terms of the Treaty of Berlin are given at the beginning of the present article. During 1876 the Sultan was changed more than once; Abdul-Aziz (succeeded 1861) was set aside and presently died; then came Murad V., to be deposed in favour of Abdul-Hamid II. In terms of the Anglo-Turkish Convention of 9th June 1878, Great Britain undertook the protection of Asiatic Turkey, if necessary 'by force of arms,' and in return the Sultan promised to execute necessary reforms, in guarantee of which the British were allowed to 'occupy and administer' Cyprus. The Marquis of Salisbury subsequently specified certain reforms in Asiatic Turkey, including the abolition of tithe-farming, and the formation of a gendarmerie and of tribunals under the control of Europeans. In January 1879 the Sultan promised to execute reforms 'as soon as the finances of the empire are placed on a better footing.' The scheme of a mixed occupation of Eastern Roumelia was abandoned (April 1879) on the proposal of the Porte not to employ Turkish troops within the province except on the demand of the International Commission, the powers of which are continued for a year. The Bulgarian Assembly has refused to admit the deputies from Eastern Roumelia, and for the present has ceased to discuss schemes for the extension of the Bulgarian frontier. The organisation of Bulgaria has been advanced at least one step by the election as its prince (April 29) of Alexander of Battenberg, a cousin of the Grand-Duke of Hessen and nephew of the Empress of Russia. Respecting one of the most interesting divisions of the Eastern Question, the English Government appear desirous of sparing the susceptibilities of the Porte, while France is anxious to be regarded as the most zealous patron of the Greeks. The Sultan has expostulated with the Khedive for dismissing his European ministers. See for history the works of Knolles, Von Hammer, and Finlay, Zinkeisen's *Osmanisches Reich in Europa* (7 vols. Gotha 1844 *et seq.*), Rosen's *Geschichte der Türkei neuester Zeit* (2 vols. Leip. 1866), Freeman's *Ottoman Power in Europe* (Lond. 1877), Creasy's *History of the Ottoman Turks* (new ed. Lond. 1877), and *Turkey and Russia* (3 vols. Edinb., T. C. Jack, 1877–79); for an account of the country and customs, Baker's *Turkey in Europe* (Lond. 1877), *The People of Turkey* (2 vols. Lond. 1878), by a Consul's Daughter (Mrs. Burt), and *Our New Protectorate*, by J. C. M'Coan (2 vols. Lond. 1879).

Turkish Bath', a popular form of vapour bath, in which the patient, after being subjected for some little time to a considerable temperature in a vapour chamber, is vigorously rubbed down, and is then conducted through a series of cooling chambers until he has regained his normal temperature. All secretions and accretions are thus completely removed from the skin, which is left free to perform its functions healthily.

Turk'ish Lan'guage and Lit'erature. Turkish, or Osmanli, belonging to the Western branch of the Turkic class in the Northern division of the Turanian (q. v.) family of languages, is spoken by the aristocracy of European Turkey, by all government officials in Syria, Egypt, Tripoli, and Tunis, and throughout the whole of Turkestan and the southern provinces of Asiatic Russia. Turkish employs the Arabic alphabet, adding, however, to its twenty-eight consonants, one native and four Persian characters; while Arabic and (through Arabic) Persian words have found their way so plentifully into its vocabulary, that the speech of the higher ranks is barely intelligible to the uncultured peasant. The grammar, purely Turanian, offers a striking instance of the manner in which an agglutinative language (see PHILOLOGY) can, with seemingly slender resources, express the minutest shades of thought. From a single verbal root, for example, thirty-six new bases may be produced by the interpolation of certain letters, *e.g.*, from *sev-mek*, 'to love,' *sev-dir-mek*, 'to cause to love,' *sev-me-mek*, 'not to love,' *sev-ish-dir-il-me-mek*, 'not to be brought to love one another,' &c. Though Turkish, like Finnish, seems to have made advances towards inflection, and though such cognate forms as *ish*, 'a deed,' and *ir*, 'to do,' as *göz*, 'an eye,' and *gör*, 'to see,' show that it has not always preserved the radical portion of every word intact, yet its essential difference from Aryan or Semitic inflectional languages is seen in this principle of incorporating new elements into the middle of a word, from which, indeed, its chief complexity arises. Redhouse has published a *Turkish-English and English-Turkish Dictionary* (2 vols. Lond. 1856–57), and a *Turkish Vademecum* (2d ed. Lond. 1877); and reference may also be made to Max Müller's *Science of Language* (2 vols. Lond. 1862–64), Grimm's *Ueber die Stellung, Bedeutung und einige Eigenthümlichkeiten der Osmanischen Sprache* (Ratib. 1877), Vámbéry's *Etymologisches Wörtenbuch der Turko-tartarischen Sprachen* (Leip. 1878), and Viscount Strangford's posthumous *Letters and Papers on Philology and Kindred Subjects* (Lond. 1878).

As their religion, so also the Turks derive their literary culture from Arabs and Persians; and Turkish writers are less original than numerous. Of the 2200 poets cited by Hammer-Purgstall, the chief are the epicist Lami (d. 1531), Fasli (d. 1560), author of the allegorical *Gül u Bülbül*, the lyricist Baki (d. 1600), and Omar ben Suleiman, founder of a didactic school. Bidpai's Fables were adapted from the Persian in 1540, as also was a version of the *Tuthinâme;* and the Arabic *Latha'if-i Chodscha Nassreddin Efendi* has long been the Turkish *Eulenspiegel.* Seven annalists have chronicled the events of the empire from its commencement to 1774, but all are eclipsed by Hadji Khalfah (q. v.), historian and geographer, whose successors in the field of history are handled by Schlechta-Wssehrd in his *Osmanische Geschichtschreiber der neuern Zeit* (Vien. 1856). There are and have been besides grammarians, commentators on Persian poetry (the name of these is Legion), and writers on medicine, jurisprudence, and religion. Authors, indeed, unless they read one another's works, would seem to be more numerous than

readers, and year by year the number of authors dwindles; so that twenty years hence one will probably sum up modern Turkish literature in the remark, The Turks have none. See Hammer-Purgstall, *Geschichte der Osmanischen Dichtkunst* (4 vols. Pesth 1836–38); and Dora d'Istria, *La Poésie des Ottomans* (Par. 1877).

Turk'manchai, a small town of Persia, province of Azerbijan, 64 miles S.E. of Tabriz, where, February 18, 1828, a peace was signed between the Romans and Persians, by which the latter ceded the Khanats of Erivan and Nakhichevan, and paid a war indemnity of £4,000,000.

Tur'meric, a substance obtained from the tubers of *Cucuma longa*, forming one of the chief ingredients of the renowned 'curry powder;' also useful as a chemical test for the presence of alkalies. The plant has a perennial rootstock with annual stems; the leaves are lanceolate, about a foot long, sheathing each other at the base, and from their centre a short leafy spike of cream-coloured flowers arises. It is a native of the E. Indies, where it is likewise widely cultivated. The Chinese T. is superior to that of Madras, Bengal, or Java. Various beautiful shades of yellow are produced by T., no other vegetable dye giving so brilliant an orange-yellow, but its colour has no permanence. Medicinally it is much employed in the East as a carminative.

Tur'ner, Joseph Mallord William, the great English landscape-painter, was born in London, at 26 Maiden Lane, Covent Garden, April 23, 1775. His father was a hairdresser, and at an early age, and with but a scant general education, T. took to art as a pursuit. Girtin, the reputed founder of the School for Painting in Water-colours, was one of his early acquaintances, and both lads were employed by John Raphael Smith, in Maiden Lane, to colour prints, and subsequently by an architect to fill in skies and foregrounds. At the age of twelve T. exhibited two drawings at the Royal Academy. In 1789 he became a student at the Academy, where for ten years he wrought assiduously, exhibiting during the period no fewer than fifty-nine water-colour pictures. The most notable of these are 'The Tenth Plague of Egypt,' 'Dutch Boats in a Gale,' and 'The Battle of the Nile.' Already had he done work of rare delicacy and strength as a book-illustrator, having contributed views to the *Oxford Almanack*, the *Pocket Magazine*, &c. In his twenty-fourth year (1799) he was elected A.R.A., and removed his studio to 64 Harley Street. Two years later, after being made R.A., he visited France, and this was only the first of a series of wide Continental rambles, during which his pencil was never idle. To this period belong 'Calais Pier' and 'The Falls of Clyde.' His reputation till now was that of brilliant water-colourist alone, but from this time he turned his attention more to oil, and during the next half-century upwards of 200 such works appeared at the Academy. In 1808 he was injudiciously elected to the chair of Perspective at the Academy, a post which he was forced to resign, his artistic qualifications being utterly thwarted by his illiteracy. The famous 'Liber Studiorum' appeared in 1808, and seems to have been suggested by Claude's 'Liber Veritatis,' a series of engravings after which had been published by Boydell with success. Produced in the fulness of the artist's powers, the 'Liber Studiorum' displays T.'s exquisite sense of ærial refinements, and incomparable power of balancing the beauties of sunshine and shadow, apart from the strongly marked conventions of his peculiar system of colour. Most of the plates were engraved by his own hand, but whether the combination of etching and mezzotint employed is really an improvement on either process by itself is an open question with critics. Other engraved series by T. are Dr. Whitaker's *History of Richmondshire*, *The Rivers of England*, *The Rivers of France*, *England and Wales*, *The Southern Coast*, the works of Rogers, Scott, and Byron, and some of Finden's beautiful works. Meantime the work of painting went on unremittingly, the period of the 'Liber Studiorum' seeing such masterpieces as 'Crossing the Brook,' the 'Frosty Morning,' 'The Sun rising through a Mist,' 'The Shipwreck,' 'Falls of Schaffhausen,' 'The Blacksmith's Shop,' and 'Wreck of the Minotaur, Spithead.' Disappearing suddenly from London, as suddenly to reappear, he passed great part of his life in the closest study of nature. In sketching, his manipulation is so dexterous and magical that paper and pigments are lost in the sense of an atmospheric medium illuminated by colour, and stretching into illimitable space. Besides those already mentioned, his greater works are 'The building of Carthage,' 'Hannibal crossing the Alps,' 'The Bay of Baiæ,' 'Mortlake,' 'Ulysses deriding Polyphemus,' 'Childe Harolde,' 'The Slave Ship,' 'The Burial of Wilkie,' 'Death of Nelson,' 'Hail, Rain, and Speed' (a railway train by night), and 'The Fighting Téméraire.' Ruskin, T.'s most eloquent advocate, is betrayed into extraordinary exaggeration of the neglect which the painter suffered in his lifetime. At his death, which took place at Chelsea, 19th December 1851, he had amassed by his art a fortune of £140,000, and by his will he disproved the charge of vulgar avarice, based on the mysterious eccentricity of his life, for he bequeathed some fifty of his finest works to the National Gallery, and devoted his gains to the foundation of an asylum for decayed artists. T.'s benevolent purpose miscarried through a technical defect in the will; but on the score of benevolence as well as artistic fame he was entitled to his resting-place beside Reynolds in the crypt of St. Paul's, where a statue to him was raised in 1862. In the *Modern Painters*, which took the world of art by storm some thirty years ago, Ruskin extolled T. with an extravagance of splendid eulogy which for a time silenced dissent, but a reaction of sentiment is already visible. Above everything else T. was lauded as a colourist, as the only painter of sunshine, the perfecter of the colour chord by means of scarlet, and it is exactly T.'s gifts of colouring which are now challenged by the 'higher' critics, who urge that what now passes for extraordinary imaginative resource will, in an impartial estimate of T.'s art, be curtly dismissed as exaggeration and artifice. No one has disputed the pre-eminence asserted for T. by Ruskin as the painter of the sea in all its 'power, majesty, and deathfulness.' Perhaps the greatest sea-pieces ever painted are the tragic 'Slave Ship' (1840) and the 'Snowstorm' (1842). Ruskin wrongly claimed T. as a Pre-Raphaelite. All authorities now agree that in his closing years the brain, and with it the eye of the painter, became diseased, and hence the incoherence of his later works. All divisions of his art into periods must give way on examination, for it is found that the development is not exactly traceable, that the periods intermix and overlap, that naturalism invades idealism, that simple effects and unobtrusive truths are interspersed by Claude-like reveries. 'A subtle and delicate but unfaithful draughtsman, a learned and refined but often fallacious chiaroscurist, a splendid and brilliant but rarely natural colourist, a man gifted with wonderful fertility of imagination and strength of memory'—such was T. in the opinion of Mr. Hamerton, his latest and most critical biographer. See Ruskin's *Modern Painters*, and the Lives by W. Thornbury (Lond. 1861), and Hamerton (Lond. 1879).

Turn'er, Sharon, an English historian, was born in London, September 24, 1768. The first fruits of his historical investigations appeared as *History of the Anglo-Saxons* (vol. i. 1799), and at once established his reputation. He continued his narrative down to the reign of Elizabeth, the last volume of the series being published in 1829. The later portions of the work are of less value than the earlier portion. Among his minor productions may be maintained, *Inquiry respecting the early Use of Rime* (1802), *A Vindication of the Genuineness of the Ancient British Poems of Aneurin, Taliesin*, &c. (1803), which was called forth by the strictures of the *Critical Review* (1800) on the first volume of his history, *Sacred Meditations* (1810), and *The Sacred History of the World* (1832). After many years of failing health T. died in London, February 13, 1847.

Turnhout', a town of Belgium, 24 miles N.E. of Antwerp, forming the terminus of a branch line of the Brussels and Antwerp Railway. It has several bleach-works and paper-mills. Pop. (1876) 15,743. On the heath of Tiel, in the neighbourhood of T., Prince Maurice of Nassau with 800 Netherlanders annihilated a picked army of 2000 Spaniards under Count Varax, January 24, 1597. Here also, on 27th October 1789, the Austrians were defeated by the patriots under Van der Mersch.

Turn'ing consists of the shaping or cutting down of hard substances while in rotation by means of special cutting or abrading tools. Articles in wood, bone, ivory, iron, steel, brass, and other metals are turned, and the process is equally applied to the production of buttons weighing only a few grains, to the shaping of enormous propeller shafts of screw-steamers, and to the boring of guns weighing many tons. The lathe and appropriate cutting-tools are the essential instruments. The simplest form of lathe consists of a framework on which is placed a horizontal *lathe-bed*, over which is mounted at one end the *lathe-spindle*, moved by

a *driving pulley* set in motion either by foot or by power. Attached to the spindle is the *fixed head-stock*, and at the opposite extremity of the bed, but capable of being moved backwards and forwards, is the *movable head-stock*. On the front of the lathe-bed is mounted the *saddle* having the *tool slide* or rest on which the cutting or shaping tools are held while they are pressed against the material on which the T. operation is being performed. The substance to be turned is centred and fixed against the fixed head-stock by means of a *chuck* or *face-plate* on the one side, and in the *screw spindle* of the movable head-stock at the other, the revolution of the lathe spindle by the driving pulley giving the material its motion of rotation. From these simple elements the lathe develops by addition and modification, and endless variety of complementary adjustments and appliances for reversing motion, for altering speed and power, for moving longitudinally the object to be turned, for fixing and moving the cutting-tools, for spiral T., and for producing innumerable curvilinear combinations for decorative purposes. For the production of an engraved pattern formed of a variety of curved lines, such as may be seen on the backs of watches, on bank-notes, &c., a *rose engine-lathe* is employed, in which rotatory motion is combined with an oscillating motion (either of the work or the cutting-tool), obtained by the use of suitable cams or *rosettes* having wavy edges. Though the lathes for wood T. and for all other T. operations are the same in principle and operation, many mechanical details and variations of structure are found in engineering lathes which are not necessary for the T. of wood. The implements ordinarily used in T. wood are chisels with skew edges, and gouges or curved chisels; but for under-cutting and scooping out internal work, special forms of cutting-tools are required. In cases where large quantities of any one form and size of a turned article are required, such as for tool-handles, or chair or table legs of uniform pattern, an enormous economy of time is effected by having single cutting-tools of the contour of the article to be turned fixed to the lathe. For this purpose a sliding frame to suit the dimensions of the article to be made is arranged and fixed between the head-stocks of the lathe. The slide contains two instruments or knives made the entire length of the article, the first for roughing out the work, and the second for finishing it accurately and unerringly to pattern. Both these tools are set on skew to take the cutting action in detail and so prevent the enormous strain which would be caused by cutting at every point of a lengthened surface at the same instant. By means of this device a table-leg which would by handiwork require an hour's T. is finished in less than a minute, and indeed more time is occupied in fixing and removing the work than in T. Thread-spools are fixed, turned, and thrown off with wonderful rapidity by automatic machinery. The tools for T. iron, steel, and hard metals are always fixed in a tool-rest. They are simple in outline, and narrow in their cutting-edges, but they must be made of the finest hard-tempered steel, and of great strength.

Tur'nip (Lat. *Terræ napus*) is the cultivated *Brassica rapa* of Linnæus, included by Dr. Boswell in his *B. polymorpha* (see RAPE). Two varieties are apparently found in a wild state in Britain, the one biennial (*sylvestris*), the other annual (*Briggsii*). The first of these scarcely differs from the cultivated T., except in having a thin, stringy root. It may be only the plant retrograding to its original wild form. The use of the T. extends back to the time of the Greeks and the Romans. It would appear to have occupied a similar position in Roman culture that it does in the husbandry of the present day. Columella, who wrote on horticulture early in the 1st c., recommended that the growth should be abundant, as the supply not required for human food could with advantage be given to cattle; and his testimony coincides with that of Pliny in esteeming the T. next in utility and value to the cereals. We have no record of its introduction into England, nor any early mention of its use. In the reign of Henry VIII. the T. was eaten baked, or roasted in ashes, and the tender tops used as a salad. During Elizabeth's reign, boiled T. was a favourite dish. The T. is now widely grown both for domestic use and farm-stock feeding. For household service, the root, in broths, soups, stews, and entire or mashed as a table vegetable, is general in all temperate climates; the leaves and flower-shoots are used as greens, and the seed-leaves as a salading. Numerous varieties are in cultivation, varying in shape as globose, oblong, depressed; in period of maturity—summer sorts and winter sorts—and in delicacy of flesh and flavour. The Swedish T., or 'Swedes' of agriculturalists, which was introduced into Britain from northern Europe at a comparatively recent date, is *B. rutabaga* of De Candolle. It may be known from the T. and other near allies by the glaucous hue of the radical leaves, the pale buff-orange tint of its larger flowers, and the shape of the root.

Field culture of the T. has proved of great advantage in British agriculture, supplying a very desirable rotation crop, and providing a winter food for cattle and sheep, which was previously a desideratum. The system is carried to perfection in Scotland, where the climate admirably suits the requirements of the T. When the crop is gathered, the roots either serve for present feeding, or may be stored in house or heaps for future service. Frequently about a third of the crop is left on the ground, to be eaten by sheep, which are from time to time transferred to certain portions of the field, and confined to the desired limits by movable fences. The land thereby receives throughout a supply of good manure. As to soil, the T. thrives best in one that is rich and free. The mode of culture differs according to the characteristics of the soil. By the gardener the seeds are sown and allowed to grow much closer than by the farmer. In the Himalaya, the T. is cultivated up to 15,000 feet. During very dry seasons, the T.-leaf is liable to the attack of mildew, to the great detriment of the crop; also to gouty excrescences on the root (called anbury), arising from the presence of insect grubs. The malformation of the root into the state called 'fingers and toes,' or *dactylorhiza*, sometimes produces much loss—the root dividing, and becoming hard and worthless. This disease seems to be a tendency of the plant to return to its *wild* form, and is best met by the farmer using new and selected seed. As the T. for food purposes contains nearly 93 per cent. of water, and no starch, it is not a nourishing article of diet.

Tur'nip Fly, a term applied to various insects, the larvæ of which are destructive to the turnip plant. *Anthomyia radicum* is a species of T.-F. belonging to the family *Muscidæ*, which includes the house-fly and its neighbours. The larvæ attack the root of the turnip. Another species is the *Haltica nemorum*, often named the 'turnip-flea,' a species of beetle, represented in America by the *H. striolata*. It attacks the leaves and root of the turnip. This species is common in meadows in Britain from April to October, and may be recognised by two yellow stripes on its wing-cases.

Turn'stone (*Cinclus interpres*), a species of *Grallatorial* or wading birds, so named from its habit of turning over small stones in search of marine worms and other animals on which it feeds. The T. is of a white and black colour, the latter hue predominating on the breast and upper part of the back. The under parts are a pure white, and the legs and toes are orange. The average length is 9 inches. The T. also occurs in N. America. Its nest is built on the coast-line, and the eggs, which number four, are coloured of an olive-green hue, streaked with brown. The breeding-season occurs in June. The T. in Britain breeds chiefly in northern islands.

Tur'pentine is an oleo-resinous product obtained from the trunk of various trees, chiefly of the coniferous class; but a similar substance also called T. is yielded by two species of *Pistacia*. T. is a more or less viscid body, resulting from the solution of several resins in the oil of T., popularly known in its separate form as spirit of T. The following embrace the principal kinds of T. recognised in commerce. *Common T.*, a product largely obtained in the United States from various pine-trees, but principally from *Pinus palustris* and *P. Tæda*, while essentially the same substance is produced in Germany from the Scotch fir, *P. sylvestris*. The substance has the appearance and consistence of honey, with a pungent, aromatic odour and a hot taste. Distilled, either by itself or with water, it separates into oil of T., which comes over, leaving in the still rosin or colophony, and it is in these separate forms that T. comes principally into commerce. *Bordeaux T.* is an analogous substance yielded by the sea pine, *P. maritima*. *Strassburg T.*, which forms a clear transparent liquid, is yielded by the silver fir, *Abies pectinata*, and the spruce fir, *A. excelsa*. *Venice T.*, yielded by the larch-tree, *Larix Europæa*, is a viscid, opaque, brownish liquid with a rather disagreeable odour. *Hungarian T.* is yielded by *Pinus pumilio*, and *Carpathian T.* by *P. cembar*, the product in both cases being a clear thin liquid. Canada

Balsam (q. v.) is also a T., and so is Burgundy pitch. *Chian* or *Cyprus* T. is obtained in the Levant from *Pistacia terebinthus*, and in Asia Minor from *P. vera*. It may be obtained clear and of a yellow tinge, but usually is somewhat cloudy with a greenish hue It is nearly allied to mastic, a substance obtained from another tree of the same genus. The various kinds of T. are also used as varnishes, but very largely they are separated by distillation into Rosin (q. v.) and Oil of T. (q. v.).

Medicinal Properties of T.—T. is employed in medicine as a stimulant, diuretic, and anthelmintic, and also as a styptic in cases of hæmorrhage from the lungs and stomach. T. is the most actively stimulating of all the diuretics, and may be employed in urinary incontinence dependent on debility of the bladder, in passive hæmaturia, and in amenorrhœa when great local debility exists.

Tur'pentine, Oil of, is obtained by distillation from the various kinds of commercial turpentine and also by distillation of fir leaves, tops, and cones. All the varieties of oil have the same ultimate chemical composition, $C_{10}H_{16}$, but they vary in physical and optical properties, and are really mixtures of two or more distinct hydrocarbons. Its chief use is as a solvent for varnishes and certain kinds of painters' colours.

Tur'pentine Tree is *Pistacia Terebinthus*. See PISTACIA.

Tur'pin, or, as the name appears in the oldest Latin documents, **Tylpi'nus**, a bishop of Rheims, who died about 800 A.D., and who is said to have been a friend and companion of Karl the Great. His name was used to give credit to a work, *De Vita Caroli Magni et Rolandi*, the first part of which is supposed to have been written by a Spanish ecclesiastic of the 11th c., to encourage the pilgrimage to Compostella; while the second part is assigned either to Pope Callixtus II., or to an unknown ecclesiastic who had accompanied him on a visit to the shrine of St. James. Frequently translated, redacted, and utilised as an authority, it exercised a wide influence on the subsequent literature of the Charlemagne legend. It is printed in Simon Schard's *Rerum Germanicarum Chronographi* (1566), Reuber's *Scriptorum qui Cæsarum et imperatorum, &c.* (Hanau 1619), and Reiffenberg's edition of the *Chronique de Philippe Mouskes* (Brussels 1836). Ciampi gave a separate edition (Florence 1822); and Gaston Paris reviewed the history of the work in his *De Pseudo Turpino* (Par. 1865).

Tur'pis Cau'sa, a phrase of Roman law imported into Scotch law, denoting an immoral consideration as the basis of an obligation. When the immorality is on the side of him who has given the consideration, he is not entitled to restitution; if it lie with the receiver, the reverse is the case; if it lie with both, then possession prevails.

Tur'quois or **Tur'quoise**, an opaque precious stone, of a greenish-blue colour, consists essentially of a phosphate of alumina coloured with copper. It is only found in a mountain region in Persia, where it occurs in veins traversing the rocks in all directions; impure varieties, valueless as precious stones, being found in Saxony and Silesia. The name T. is a French form of Turkish, and indicates that the stone first came to Western Europe by way of Turkey. Pure pieces the size of a hazel nut are very rarely obtained. The T. has been known and highly esteemed as a stone for rings and jewellery generally from remote times, and it is elaborately described by Pliny. Singular properties were in mediæval times attributed to the T. It was supposed to strengthen the eyes and cheer the mind of its wearer; it saved him from accidents, it paled in his sickness, and lost colour on his death. In Germany it is the proper stone for a betrothal ring; the permanency of its colour indicating the constancy of the lover's affection.

Türr, General Stephan, was born at Baja, in Hungary, 10th August 1825, became a lieutenant in the Austrian army in 1848, and served his first campaign in that year in Italy under General Radetzky. In January 1849, in obedience to the command of the revolutionary government of Hungary, he deserted to the Piedmontese, and was appointed Colonel of the Hungarian legion in the service of the latter. After the disaster of Novara he passed into the duchy of Baden, and served in the revolutionary army, which, however, was soon defeated. The Hungarians took refuge in Switzerland, the government of which aided many to emigrate to the United States. T., however, remained in London on a pension granted by the Sardinian government. On the outbreak of the war with Russia, he went to the Crimea, took part as a volunteer in several battles, and received a commission from Colonel M'Murdo. Despatched in 1855 to the Danubian provinces to purchase horses, T. was arrested at Bucharest by the Austrians as a deserter, sent to Vienna, tried by a court-martial, and condemned to death. On the vigorous remonstrance of the British government his sentence was commuted to perpetual banishment. In the Italian war of 1859 he was a member of Garibaldi's staff, and in the war in Sicily his aide-de-camp, and before Palermo was appointed a general of division. T. was appointed by Victor Emmanuel in 1861 general of division in the army of Italy, and Commandant of Naples. In the same year he married the Princess Adeline Wyse Bonaparte. He resigned his command in 1864, and in 1869 returned to Hungary, where he now (1879) resides, busied with canals and other industrial undertakings. See his *Arrestation, procès et condamnation du Général T. racontés par lui-même* (1863), and *La Maison d'Autriche et la Hongrie* (1865), and Schwarz, *S. T.* (Vien. 1868).

Turreti'ni is the name of a celebrated family of Genevan theologians, descended from a Gonfaloniere of Lucca, whose son, **Francisco**, had to take refuge in Geneva on account of his religion in 1579, and there died.—**Benedictus T.**, his son, was born at Zurich, 9th November 1588, became pastor at Geneva in 1612, and professor of theology in 1618; represented the Genevan Church at the Synod of Alais in 1620, and in the following year concluded successfully an alliance between Geneva, the States-General of Holland, and the Hanseatic towns. He died 4th March 1631, leaving behind him many theological writings.—**Franciscus T.**, son of the preceding, was born 17th October 1623, studied at Geneva, Leyden, Paris, Montauban, and Nismes; became pastor, and in 1653 professor of theology in his native city, where he distinguished himself as an opponent of Amyraldism, and a staunch upholder of the decisions of the Synod of Dort, ultimately formulating his views in 1670, in conjunction with several Swiss divines, in the Klostic *Formula Consensus*. He died 28th September 1687. His most celebrated work is the *Institutio Theologiæ Elenchticæ* (Geneva 1679–85), of which a reprint, with selections from his other writings, was published at Edinburgh (1847-48).—**Joannes Alphonsus T.**, his son, born 13th August 1671, abandoned the strict Calvinism of his ancestors in favour of a mode of thought resembling the contemporary Latitudinarianism of England, and endeavoured to unite the various sections of the Protestant Church on a more liberal basis. It was chiefly owing to his efforts that the Genevan Church resolved in 1706 to make the signing of the Formula Consensus, drawn up by Francisco T., optional in the case of candidates for the pastorate. T. studied theology at Geneva and Leyden, visited the English universities, where he formed several personal friendships, and spent some time in Paris. In 1697 he was appointed to the chair of ecclesiastical history at Geneva, from which in 1705 he was transferred to that of systematic theology. He died at Geneva, 1st May 1737. Of his numerous works the most important are *Cogitationes et Dissertationes Theologicæ* (Gén. 1703, 1737); *De Veritate Religionis Christianæ* (Gén. 1721-23); and *Hist. Eccl. Compendium* (Gén. 1700, 1734), often re-edited and translated. A very full account of the family is given in Herzog's *Realencyklopaidie*.

Turr'et-Ship, an ironclad ship of war, whose armament is mounted in one, or more than one, low circular tower or turret placed on the deck, and revolved by hand or steam power. This arrangement affords a wide horizontal fire, and capability of firing the same guns on both sides of the ship—a great advantage over broadside guns, which can only be trained through small arcs. The maximum of offensive power and minimum of armoured area are combined in a T.-S. The sides of the ship are made much lower than in broadside ironclads, and this reduction of surface enables the remaining portions to be very heavily armoured, and guns of the weightiest nature to be carried. The advantages to be derived from the use of revolving turrets for land and coast defence were clearly pointed out by M. Baltard in a work published at Paris in 1831; T. R. Timby, of Saratoga, U.S., caveated in 1843 the invention of a revolving turret of iron for use on land or water; Captain Ericsson designed in 1855 the 'monitor' type of vessel; and about the same time Captain Cowper Coles, R.N., contrived a

turret system differing from Ericsson's in some important particulars. The United States adopted Ericsson's plan, while Coles' system was put in practice in the British navy. The *Monitor*, designed by the former inventor, was launched early in 1862. Her deck was only 18 inches above the waterline, and on a metal ring in the centre of the deck a turret (20 feet in diameter and 9 feet high) was placed, which had two ports for 11-inch guns, the whole rotating on a central spindle by steam. She proved a most formidable ship, and her name is now applied to all ironclads constructed on the same principle of low freeboard with gun-turrets. Her defects were remedied in other monitors subsequently built. The *Dictator* class of monitor carries 10 inches of plate iron (backed by 3 feet of oak) on the sides and 15 inches in the turret walls, which enclose two 15-inch guns. Some monitors have two, others three turrets. The *Miantonomoh* and *Monadnock* have made successful voyages in the Atlantic and Pacific. The chief disadvantages of these monitors, arising from the turrets being raised so little above the water, are that the guns cannot be used in heavy weather, for the ports must then be closed to keep out water, and that the revolution of the turrets is in danger of being stopped by a plunging fire from broadside guns directed to the junction of the turrets with the deck. Different classes of British ironclads carry Coles' turrets at an elevation considerably over that of American monitors. The turrets pass through the upper deck, and rest on a broad base and cone rollers on the deck below, rotation being effected by a winch or steam power. The *Monarch* is a double-turreted full-rigged ship. The sister ship to this ironclad was the ill-fated *Captain*, designed by Captain Coles, which foundered, owing to pressure of sail assisted by a heavy sea and a want of proper stability, off Cape Finisterre in September 1870, with the lamentable loss of 500 lives, including that of the unfortunate designer. The class of turret-ships for coast defence, of which the *Glatton* is the type, are mastless and sailless 'breastwork monitors,' having a low freeboard, an iron plated deck, and one or more turrets commanding an all-round fire. The bases of the turrets are protected by a massive breastwork rising 6 feet from the hull, and the freeboard is thus heightened for a considerable portion of the vessel's length. Over the turrets a hurricane or flying deck is erected, which serves for the stowage of boats. The same general plan is followed in the much larger seagoing turret-ships, of which the *Thunderer* or *Devastation* is a typical example. The *Thunderer* has a freeboard of 4 feet 6 inches, plated with 12 inches of iron, and two turrets (15 inches thick), each with two 35- or 38-ton guns. The *Inflexible* class are constructed on the 'central citadel' principle, the middle part of the ship—embracing turrets (18-inch armour), machinery, and magazines—being protected by an iron citadel, 2 feet thick, extending from 6 feet below the waterline to 10 feet above it for a length of 110 feet. The turrets are placed diagonally, to command a fire ahead and astern as well as abeam. The ends before and abaft the citadel are unarmoured, and serve to accommodate the crew and to carry coal. The armament consists of four 81-ton guns throwing a projectile weighing nearly three-quarters of a ton. The monster guns of these turret-ships are loaded and worked by hydraulic machinery.

Turritell'a, a genus of Gasteropodous Mollusca, the type of the family *Turritellidæ*, in which there is a tubular spiral shell, frequently turreted. The operculum is horny, and the foot small. The T. is abundant in existing seas.

Tur'tle, the name given to various members of the Reptilian order *Chelonia* (q. v.). In the section known as that of the *Eureta*, and in which the T. are included, the beak is hooked and exposed, and the snout blunted. The *tympanum* is concealed by the integument. The front pair of limbs are longer than the hinder pair, and are converted into swimming-paddles. The fingers or digits are flat and long, and are bound together by the integument or skin. The nails are but feebly developed. The skin or integument may be soft and rugose, as in *Sphargis*, or may be covered with thick epidermic plates as in the familiar tortoise-shell T. (*Chelone imbricata*). Properly speaking, these two genera are the only true turtles, but other members of the order Chelonia are often so designated, as *e.g.* the Mud T. The Luth or Leathery T. (*Sphargis coriacea*), named from the soft, leathery-like integument which coats the shell, occurs in the Atlantic, Pacific, and Indian Oceans, and may measure 6 feet in length, attaining a weight of over 1600 lbs. The skin of the back is ridged, or elevated into a series of very prominent lines. The lower jaw is markedly hooked, and the toes are devoid of nail. The colour is a dark brown spotted with yellowish patches. The Hawksbill T. (*Caretta* or *Chelone imbricata*) is the species from the epidermic plates of which 'tortoise-shell' is obtained. It is a native of tropical seas, and may attain a length of from 3 to 4 feet. The plates are stripped off the back after the animal has been exposed to a strong heat. A second set of plates, of inferior quality, grows after the first have been removed. The colour of the Hawksbill T. is yellowish, marbled with brown, the under parts being of a dirty white. The Green T. (*Chelone viridis* or *mydas*) is the species best known on account of its furnishing the materials for the famous soup. It is common at the Antilles and round the Ascension coast. It is captured by intercepting it on its native sands, and turning it over on its back, its unwieldy bulk rendering it impossible for the T. to right itself. It may be captured at sea by harpooning, and also by means of the Remora (q. v.) or sucking-fish. The eggs of this T. are accounted great delicacies. The tenacity of life of the Green T. and of other species has long been a subject of remark. These reptiles will exhibit signs of sensitiveness in their tissues for weeks after decapitation—a fact depending on the slow, languid circulation, and on the low vitality of the tissues. Such forms as the Snapping T. (*Troiynx ferox*) and the Tyrse (*T. Niloticus*) belong to the group of the soft Tortoises (q. v.). The Loggerhead T. (*Caouana caretta*), allied to the Hawksbill T., is a fierce species, biting with great force and severity on provocation. It has a wide range, occurring in the Atlantic and in northern limits.

Tur'tle Dove (*Turtur auritus*), a species of *Columbidæ* or pigeons migrating from Africa to England, arriving in Britain in May, and leaving in August or September. The average length of the T. D. is about 11 inches. Its colour is a pale brown, marked with a darker hue above. Four rows of black feathers, tipped with white, decorate the side of the neck; and the top of the head is of a slaty-grey hue, while the under parts are white. A purple tint pervades the feathers of the breast. This bird is tolerably common in the southern English counties. The nest is built on the forked bough of a tree, and both parents sit on the eggs during incubation. A single brood, averaging two in number, is produced in the course of each year. The bill is more slender than in other pigeons, and the upper mandible is prominently ridged. An allied species, the Laughing T. (*T. risorius*), is so named from the peculiar grating nature of its cry. Its prevailing colour is a brownish grey, a black collar encircling the hinder part of the neck.

Tus'can Order of Ar'chitecture. See COLUMN.

Tus'cany, now a part of the Kingdom of Italy (q. v.), was from 1569 till 1860 a sovereign grand-duchy, surrounded by Parma, Modena, the Papal States, and the Tyrrhene Sea. T. corresponds to the N. of the ancient Etruria (q. v.). After the fall of the Roman Empire, it passed to the Goths, then to the Lombards, then to Karl the Great, and about 828 was erected into a marquisate, of which the S. part was bequeathed to the Pope by the Countess Mathilda (1115). In the N. gradually arose the flourishing republics of Pisa, Siena, Lucca, and Florence (q. v.), of which the latter, under the Medici (q. v.) family, became the chief. T. was made a duchy in 1531, a grand-duchy in 1569. The Medici line dying out in 1737, it was passed by the Treaty of Vienna (1738) to Francis, Duke of Lorraine. T. was annexed to Sardinia (q. v.) in 1860, when it had an area of 8440 sq. miles, and a pop. of 1,826,830. See Von Reumont, *Geschichte Toscana's seit dem Ende des Florentinischen Freistaats* (2 vols. Gotha 1876-77).

Tus'culum, an important city of ancient Latium, 15 miles S.W. of Rome, was founded according to legend by Telegonus, son of Odysseus and Circe. From the time of the battle of Lake Regillus down to the conclusion of the Latin War in B.C. 335, T. is frequently mentioned by Roman historians, and with few exceptions as a faithful ally of the imperial city. From that time till the close of the Republic it sinks altogether out of sight, but from about 80 B.C. it was brought into notice again by Lucullus as a fashionable resort of the leaders of Roman society. After the downfall of the Empire T. regained not a little importance, its counts being for some centuries supreme in Rome. It was destroyed at the instance of the German Emperor in 1191. The ancient town has been identified with the modern Frascati (q. v.).

Tuss'ac Grass (*Dactylus cæspitosa*), a native of the Falkland Isles, Fuegia, and S. Patagonia, is so called from its densely compact growth of large isolated hillocks or 'tussocks' of from 3 to 6 feet high, from which spring annually long leaves and robust leafy stems. The young growth contains a large quantity of saccharine constituents, rendering the plant a useful food-supply. Several attempts made to establish it upon seaside districts in Scotland have as yet failed of success.

Tuss'er, Thomas, best known as the author of *Five Hundred Pointes of Good Husbandry*, was born probably about 1515, at Rivenhall, near Witham, in Essex. From his rhyming autobiography it would appear that he served as a chorister first at Wallingford Chapel, and afterwards at St. Paul's, had the honour of being flogged if not instructed by Nicholas Udall at Eton, was attached for a number of years to the court, probably in the capacity of a musician, and at a later date kept a farm for some time in Suffolk. He probably died at London somewhere between 1580 and 1585. His will was privately printed in 1846 at Great Totham, Essex. The *Five Hundred Points* were first published in 1573, having been preceded by *A Hundred Good Points*, which had seen at least five editions since its appearance in 1557. In rude rustic rhymes, which have hardly a claim even to the name of verse, he inculcated a good amount of sound agricultural wisdom; and the book is still of interest for the glimpses it affords of the country life of the times, as well as for occasional passages of quaint and vigorous expression. The best editions are Dr. Mavor's (1812), Arber's (1870), and the English Dialect Society's (1878).

Tussila'go is a genus of *Compositæ* consisting of a single species, *T. farfara*, a very common British plant on damp heavy soil, and called popularly the 'coltsfoot,' from the shape of its leaf. Its heads of bright-yellow flowers appear in March and April, succeeded by fruits bearing a soft snow-white pappus. The leaves, which develop subsequently, are broadly cordate and angular, cobwebby above and densely cottony beneath. It is dispersed through Europe, Asia, and North Africa. The name T. is derived from the Latin *tussis*, and the leaves are still used as a *cough* remedy, more especially for asthma. The web from the leaves makes a good tinder. *Petasites vulgaris*, or butter-bur, was formerly included in the genus T. Its leaves, in shape and size like those of the garden rhubarb, render it a conspicuous plant by river sides in many parts of Britain.

Tuss'ock Moth (*Laria pudibunda*), a species of *Lepidoptera* (q. v.), the larvæ of which effect much damage in hop plantations. It attains the length of an inch. It is white below, and of a greyish hue, marked by irregular dark lines above.

Tuticorin (*Tutukudi*), a town in the district of Tinnevelly, Madras, British India, near the S. extremity of the peninsula, 70 miles N.E. of Cape Comorin, and 513 S.W. of Madras by rail. Pop. (1871) 10,565. In the roadstead here, where ships ride safely 2½ miles from the shore, is conducted all the sea-borne trade of the district. In 1874-75 the exports were valued at £890,337; the imports at £406,453. There is a pearl-fishery in the neighbourhood. T. has acquired increasing importance as the terminus of the S. Indian Railway. The Prince of Wales disembarked here from Ceylon in 1875, and proceeded N. in the first train that opened the line.

Tu'tor is, in Scotch law, the guardian of a boy or girl in *pupilarity* (see AGE). A father is T. to his children by common law. Failing him, there may be three kinds of T.,—*T.-nominate*, *T.-at-law*, or *T.-dative*; the division being borrowed from the Roman law. A T.-nominate can only be appointed by the father, either under his will or by some writing clearly indicative of his wish. He is not generally bound to find security for his *Intromission* (q. v.) with the estate of his pupil, but the Court of Session may ordain him to do so. A T.-at-law is appointed by the Court when there is no T.-nominate, or when he dies, or does not accept. The nearest relation by the father is usually appointed if twenty-five years old and able to give security. But the T.-at-law has only the custody of the pupil's estate, his person being intrusted to his mother, or, failing her, to his nearest relative on her side. A *T.-dative* is named by the Crown when there is no *T.-nominate, nor at-law*. The office is in all cases an unpaid one, and the T. is bound to make inventories and to keep accounts. For certain important acts—selling land, for example—he requires the sanction of the Court of Session.

Tutt'lingen, a town of Würtemberg, Germany, on the Danube, 16 miles S. of Rottweil by rail. It has manufactures of cutlery, woollen goods, and leather; glue-boiling, bleaching-works, and breweries; besides some trade in corn with Switzerland. Ludwigsthal, in the neighbourhood, has large iron-hammer works. The ruined castle of Honberg overlooks the town. Pop. (1875) 7231. Here on 24th November 1643 the Imperialists defeated the French.

Tutt'y-powder, an impure oxide of zinc collected for medicinal purposes from zinc-smelting furnaces.

Tutui'la, the most central island of the Samoan group (q. v.) in the S. Pacific. Area 90 sq. miles; pop. 6000. The coast is precipitous, and the island is traversed by a sharp mountain-ridge 2500 feet high, too steep to be crossed, and clothed with luxuriant tropical vegetation. The island is nearly cut in two on the S. by the inlet of Pago-Pago, an ancient crater, which now forms a deep and landlocked harbour.

Tver, a government of Russia, surrounded by the governments of Novgorod, Jaroslav, Vladimir, Moscow, Smolensk, and Pskov. Area 25,223 sq. miles; pop. (1877) 1,568,000. From the Volchonski Forest, a range of thickly wooded limestone hills in the W., offsets running between lakes and swamps intersect almost the whole of T. In the Ostashkov district are the headwaters of the Volga, Düna, and Msta. T. is drained by the Volga and its affluents. The Volga is connected with the Msta by the canal of Vishnij Volotchok, and by the Mologa and the Tichvin Canal with the Tichvinka and Sias, which run into Lake Ladoga. There are 100 lakes in T., of which the largest are Seliger, Ochvat-Shadenje, and Steresh. One-fourth of the surface is forest. Potatoes and flax are increasingly cultivated. The chief occupations are the cutting and floating of wood, and the preparation of tar, pitch, and turpentine. In 1873 the cotton, hemp, and flax weaving industries employed 16,363 workmen.—**T.**, the capital, lies on both sides of the Volga (here crossed by a bridge of boats 680 feet long), at its confluence with the Tverza and the Tmaka, 110 miles N.W. of Moscow by rail. It has fine streets and squares, an Imperial palace, a cathedral, and thirty-three churches, several monasteries, a priests' college, a gymnasium, a technical school, a cavalry cadets' school, a teachers' seminary, a ladies' college, several benevolent institutions, and a theatre. There are 28 factories (2 cotton-spinning, 2 cotton-weaving, 1 chintz-making). Its position on the St. Petersburg-Moscow Railway and on the river Volga gives T. great transit-traffic, which is chiefly in corn and metal wares. Entirely burnt in 1763, T. was speedily rebuilt by Catharine II., who has here a monument. Pop. (1875) 38,248.

Tweed, the most famous river of Scotland, rises near Hart Fell, in the S. of Peeblesshire, flows N.N.E. through that county, then E. through the northern parts of Selkirk and Roxburgh shires, and finally N.E. between Berwickshire and Northumberland, discharging into the North Sea at Berwick after a course of 96 miles. It receives from the left the Lyne, Gala, Leader, and Whitadder; and from the right the Ettrick, with the Yarrow, the Teviot, and the Till; and it passes on its course the towns of Peebles, Innerleithen, Melrose, Kelso, Coldstream, and Berwick. The varied beauty of the scenery through which it flows—wild moorlands, winding vales rich in wood or pasture, and broad-stretching finely-cultivated plains—as well as its romantic and historical associations, make T. the most interesting of Scottish rivers. There is hardly a place upon its banks, or those of its tributaries, which is not celebrated in song or story. The genius of Scott in particular has conferred upon it a world-wide fame. The T. is hardly navigable above Berwick. It is celebrated for its trout and salmon fishery.

Tweed'mouth, a small seaport of Northumberland, on the right bank of the Tweed, opposite Berwick, of which it forms a suburb, and with which it is connected by a fine old stone bridge of fifteen arches and a magnificent railway viaduct. It has manufactures of steam-engines and mill machinery, sailcloth, cordage, and linens. Pop. (1871) 2809. Adjoining it is Spittal, a favourite watering-place, with a pop. (1871) of 1742.

Tweeds, a class of woollen textiles of a stout, close-woven, lightly-felted texture, used specially for male clothing, but also

to some extent employed for ladies' cloaks and mantles. The manufacture originated at Galashiels, and early in the present century took root in the towns of the Tweed valley, whence it is commonly supposed the name T. arose; but in reality the name is due to a mistaken reading of 'Tweel,' under which term the fabric was originally known. T. are woven as twills, and the distinguishing characteristics of the fabrics are strength and flexibility, due in the first place to the genuine and excellent quality of the woollen yarns of which they are woven; and, secondly, to the fact that they are but lightly raised and cropped in the finishing processes. Neutral colours predominate in T.; whites, greys, browns, and blacks being the predominant colours, and these are woven into checks, stripes, or mottles, the patterns being in all cases small and little pronounced. A general distinction may be observed between Scotch T. and English T., the latter being generally close 'cropped' and finished as dress T., while the former have a somewhat rougher woolly surface. The manufacture of T. is now the most important department of the woollen industries, and it has spread from its original seat—which, however, continues to be its principal centre—to most of the districts engaged in woollen manufactures. In Aberdeen, at Bannockburn, at Alva near Stirling, and at Paisley, in Scotland, the industry is prominent; and in England, Leeds and other Yorkshire towns and the West of England woollen regions are also extensively devoted to the manufacture. See WOOLLEN MANUFACTURES.

Twelve Tables (Leges XII., Lex XII. tabularum) is the name given to the first codification of Roman law drawn up about the middle of the 5th c. B.C. According to the account given by the Roman writers (Livius bk. iv., Dionysius bk. x., Cicero de Rego ii., &c.), three commissioners were sent to Greece in B.C. 454, in accordance with a plebiscitum approved of by the Senate, to examine into the legal institutions of the various cities, and on their return ten men were elected in 451 by the Comitia Centuriata to draw up a code for Rome (decemviri Legibus scribundis), the other magistracies being for the time suspended. By the end of that year ten tables had been drawn up and confirmed, but as it was thought that more were required, Decemvirs were again elected for B.C. 450, and two tables were added to the collection, making in all twelve. These were then inscribed on bronze and set up in some public place; and whatever the meaning of the passage in *Livy* (vi. 1) about the burning of the city by the Gauls may be, it is evident that the copies of these laws extant in the time of Cicero were regarded by every one as unimpeachably genuine. The T. T. contained enactments bearing on both public and private law; and as regards both, it seems probable that they contained no new legislation, but merely embodied the customary law of the time, now first fixed by writing. On points with which Roman law had not hitherto dealt, there is no reason to doubt the truth of the tradition that Greek or other foreign sources were freely drawn upon. In course of time the Public law (Jus publicum) underwent great alterations, but the private law continued unchanged though somewhat amplified. Many commentaries were written upon the T. T., but the only one that is now extant is that by Gaius, fragments of which are contained in his *Digest*. See the remarks on the so-called Decemviral Legislation in the histories of Mommsen and Ihne, and Dirksen's *Uebersicht der Zwölf-Tafeln-Fragmente* (Leip. 1824), and Schott's edition (Leip. 1866).

Twes'ten, August Detlev Christian, a Protestant theologian, was born at Glückstadt, April 11, 1789, studied at Kiel, and was successively a teacher in the Berlin gymnasium, professor of theology at Kiel (from 1814), and professor at Berlin (from 1835) in room of Schleiermacher. He died January 8, 1876. His chief writings are *Vorlesungen über die Dogmatik der Evangelisch-Lutherischen Kirche* (vol. i. 1826; 4th ed. 1838; vol. ii. 1837), *Grundriss der Analytischen Logik* (Kiel 1834), *Matthias Flacius Illyricus* (Berl. 1876).

Twick'enham, a town of Middlesex, on the W. bank of the Thames, is 10 miles W.S.W. of Hyde Park Corner, and has three stations on the South-Western Railway. St. Mary's, with an ancient tower but red-brick nave rebuilt in last century, contains Pope's monument, erected by Bishop Warburton in 1761; and other churches are Holy Trinity (1840; reseated 1877) and St. Stephen's (1874-76). The public buildings include a handsome town-hall, a library and reading-room, the Royal Naval Female School (1856), and the Metropolitan and City of London Police Orphanage, to which a new wing was added in 1878. The site of Pope's famous villa is covered by modern residences, and Orleans House was converted (1877) into a club; but Strawberry Hill, which its builder, Horace Walpole, pronounced 'the prettiest bauble, set in enamelled meadows with filigree hedges,' remains for a monument of Gothic in the 17th c. Pop. (1801) 3138, (1871) 10,533, an increase due to the number of new villas, which, reaching to Richmond Bridge, constitute T. a suburb of Richmond (q. v.). See the Rev. R. S. Cobbett, *Memorials of T.* (Lond. 1872).

Twill, or **Tweel**, is that system of plain weaving in which the weft rises above one and shoots under two or more of the warp threads in regular succession. Twilled fabrics have therefore always a diagonal appearance.

Twi'light (Old Eng. *twy* or *twi*, 'double,' and *leoht*, 'light'), the interval of dusk which before sunrise and after sunset divides the day from the night. The word used without qualification is usually understood as applying to evening T. (Lowl. Sc. the *gloaming* = the glooming), while morning T. is distinguished as the *dawn*. The phenomenon is caused by the reflection of light from the atmosphere. The quantity reflected, and therefore the intensity of the T., at any instant depends primarily upon the distance of the sun below the horizon of the observer. The greater this distance the fainter the T., until when the sun has reached a certain limiting distance the T. ceases. This limit has been variously fixed at from 15° to 24° by different observers, the discrepancy being mainly due, no doubt, to the impossibility of noting the instant at which such a gradually diminishing or increasing luminosity ceases or begins, and also to the varying atmospheric conditions under which the observations were made. The limit usually assigned is 18°; that is to say, when the sun is 18° below the horizon, T. has ceased or has just begun. When the sun passes through the zenith of the observer, its path is a great circle cutting the horizon at right angles. In such circumstances, which are peculiar to the tropical regions, the duration of T. is at its minimum, since the sun sooner reaches the limiting distance than when its path is a great circle cutting the horizon obliquely. The duration of T. is of course much influenced by such local conditions as clouds, smoke, mist, &c., which diminish to a marked extent the intensity of daylight.

Tybee', an island at the mouth of the Savannah river, Georgia, U.S. It is 6 miles long and 3 broad, and at its N.E. end stands the large T. lighthouse. Great batteries were erected here by General Gillmore in 1862.

Ty'burn, till 1783 the site of the London gallows, where Catholic priests were martyred by Elizabeth, and Felton, Jack Sheppard, Dr. Dodd, and other notable offenders, paid for their crimes. It was situated at the W. end of T. Road (now Oxford Street), near the Marble Arch, and its name survives in the N.W. suburb, 'the elegant, the prosperous, the polite Tyburnia.'

Tycoon' (Chinese 'great lord'), or more correctly Shiogun, the title of the hereditary military despots who ruled Japan from 1192 to 1868, when the revolt of the Daimios swept away the last of the race and reinstated the Mikado in power. The T., who resided at Yeddo, did homage to the *roi-fainéant* at Miako, but ruled unrestrictedly. Hence Europeans carried away the impression that the T. was the real emperor and the Mikado a 'spiritual ruler.'

Tye, Christopher, Doctor of Music, was born in London about 1500, and educated in the Royal Chapel, of which he ultimately became organist, and for which he produced many services, anthems, and other sacred compositions. These works, though now obsolete, were for many years of great repute among musicians. An excellent example of his style is to be found in the anthem for four voices, 'I will exalt thee, O Lord!' in the second volume of Dr. Boyce's *Collection of Cathedral Music*. He translated the first fourteen chapters of the Acts of the Apostles into metre, and set them to elaborate music. T., who was musical instructor to the children of Henry VIII., received the degree of Doctor of Music at Cambridge in 1545, and died about 1580.

Tyldes'ley, a growing town of Lancashire, England, 10 miles N.W. of Manchester. It has a church and several chapels,

There are large collieries in the neighbourhood, and cotton-spinning is the chief industry of the town. Pop. (1871) 6408.

Ty'ler Insurrec'tion, a popular revolt during the minority of Richard II., which was headed by Wat Tyler, a soldier who had served in the French wars, and Jack Straw, an Essex peasant. Its immediate occasion was the imposition in 1381 of a poll-tax of 3 groats on every adult, to defray the cost of the disastrous French war; and the first blow struck was the death of a tax-gatherer, who had offered an insult to the daughter of a black-smith in Essex. From Essex the revolt spread over Norfolk, Suffolk, Sussex, and Surrey, but its strength lay in the 100,000 men of Kent, who marched on London, passing quaint rhymes from man to man, and putting to death every lawyer whom they found. The nobles fled, paralysed with fear, while the artisans of London flung open the gates of the city. Soon the stately palace of John of Gaunt at the Savoy, the new inn of the lawyers at the Temple, and the houses of the foreign ambassadors were in flames, while a band under Tyler himself broke into the Tower and dragged out and put to death Archbishop Sudbury, the Prior of St. John, and the treasurer and chief commissioner in the levy of the hated poll-tax. At Mile-End, without the city, the young king met the great mass of the peasants, whom he overawed by his fearless demeanour, and induced them to disperse by promising them charters of freedom and amnesty. However, 30,000 remained with Wat Tyler to watch over the fulfilment of the royal pledge, and this body Richard met by chance next morning at Smithfield. In the conference which ensued, William Walworth, the Mayor of London, exasperated at the insolence of T., stabbed him with his dagger, and in the scene of confusion which ensued, the king, with great presence of mind, addressed the populace, led them to Islington, and commanded them to disperse. The death of Tyler paralyzed the people, while it revived the courage of the nobility. The king, in violation of his pledge, led an army of 40 000 men through Kent and Essex, and spread terror by the severity of his executions, while in Norfolk and Suffolk the revolt was stamped out with the most ruthless cruelty. See C. E. Maurice, *Lives of Tyler, Ball, and Oldcastle* (Lond. 1872).

Tyler, John, the tenth President of the United States, was born in Charles City county, Virginia, March 29, 1790. He graduated at William and Mary College in 1806, was admitted to the bar in 1809, was a member of the State Legislature 1811-16, and 1823-25, and entered Congress in 1816. In 1825 he was elected governor of Virginia, and from 1827 to 1836 he represented that state in the Senate. In 1840 he was unanimously elected Vice-President by the Republican party, and on the death of Harrison, a month after his election, he became President of the United States. He now disappointed the expectation of his party, and rendered himself very unpopular, by opposing the bill for the erection of a national bank, and by a revival of the Presidential right of veto. The principal event in his administration was the annexation of Texas, March 1, 1845. On the expiry of his term of office he retired into private life until February 1861, when he was president of the abortive 'peace convention' at Washington. On the outbreak of the war he renounced his allegiance to the United States, and was elected to the Confederate Congress, but died at Richmond, January 17, 1862.

Tyloph'ora (*tylos*, 'a swelling,' and *phoreō*, 'to bear,' alluding to the swollen pollen-masses) is a considerable genus of *Asclepiadaceæ*, found in various tropical and warm regions of the Old World. *T. asthmatica*, a native of the E. Indies, is the most important species. Its leaves have emetic, expectorant, and diaphoretic properties, and form one of the best substitutes in India for ipecacuanha. The root has also medicinal properties. The stem yields a strong, white, silky fibre.

Tym'panum. See EAR.

Tyn'dale, William, an English reformer, memorable for his translation of the Bible into his mother tongue, was born between 1480 and 1490, probably at the manor of Hurst, near Slymbridge. After finishing his education at the universities of Oxford and Cambridge, he lived for some time as tutor in the family of Sir John Walsh, at Little Sudbury in Gloucestershire, undertaking preaching tours in the neighbouring villages, to maintain theological discussions with the local clergy, and to try his 'prentice hand as a translator on the *Enchiridion militis Christiani* of Erasmus. Meanwhile his attention had been turned to the need of a translation of the Scriptures into the vulgar tongue; and in hopes that he would procure the assistance of the Bishop of London, he departed for the capital with an oration of Isocrates done into English as proof of his capabilities. His expectation of episcopal co-operation was cruelly disappointed; and soon after (May 1524) he departed for the Continent, to prosecute his great task at his own expense and hazard. His first destination was Hamburg, but he probably proceeded to Wittemburg to see Luther. By 1525 he had begun to print his New Testament at Quantel's press in Koln; but he had only got as far as signature K when the printers were ordered by the magistrates to stop, and T. and his assistant Roye were glad to escape with such sheets as they could hurriedly seize. At Worms, to which they fled, the work was taken up by Schœffer, and before the close of 1526 two editions of the New Testament seem to have been ready for the market. Of the quarto edition only a single and imperfect copy is known to exist, and of the octavo there are no more than two. The version was based on the Greek, and controlled so far by the Vulgate and Lutheran translations. In 1527 T. removed to Marburg, and there he published through Hans Luft *The Parable of the Wicked Mammon* (1528), *i.e*, of the Unjust Steward, being a treatise on justification by faith, a work on *The Obedience of a Christian Man, and How a Christian Ruler Ought to Govern* (1528), a translation of the Pentateuch (1530), a treatise, or, according to one account, three treatises, on matrimony, and *The Practice of Prelates*. This last work, which boldly attacked the clerical abuses of the time, was in part an answer to Sir Thomas More's famous *Dialogue* (1529), in which the Catholic positions were defended with consummate skill. About 1531, Cromwell, who was then in power, was anxious to get T. to return to England, and employed Stephen Vaughan, envoy to the Low Countries, to persuade him; but T. was too wary to risk his neck under such a king as Henry VIII. Great efforts were made to entrap him, and Elyot, the envoy who replaced Vaughan, was commissioned to search him out. But T. successfully eluded the royal emissary, sometimes moving from place to place, sometimes quietly working at Antwerp. About 1532 he published a translation of the Book of Jonah and an Exposition of the Sermon on the Mount; and at length in 1534 he was able to bring out a revision of his New Testament. Of this edition, printed at Antwerp by Lempereur, only one copy, that of the Grenville Library in the British Museum, is known to exist. It was a great improvement on its predecessor. On the 23d or 24th May 1535 T. was arrested at Antwerp by the representatives of the Emperor Karl V., and conveyed a prisoner to the Castle of Vilvorde. In 1536 the reformer was formally arraigned before an imperial commission, sentence of death was pronounced on 10th of August, and on Friday 6th October he was strangled by the public executioner, and his body burned to ashes. His last words were, 'Lord, open the King of England's eyes.' Both the king and Cromwell had made some efforts to save him. T. was a man of rare sincerity of purpose and simplicity of life. He was well versed in Greek and Hebrew, had no small power of argument, and, what more than all else fitted him for his task, he was master of an English style which for unconstrained strength and natural dignity has never been surpassed. To him the literary beauty of our English version is mainly due. An almost complete edition of T.'s works was prepared for the Parker Society by Dr. Walter (1848 and *et seq.*). Mr. Arber has published a photolithographic copy of the first quarto New Testament; and Mr. Fry has produced fac-similes of the complete octavo preserved in Bristol, &c. See Anderson's *Annals of the English Bible* (1845), Westcott's *History of the English Bible* (1868), Demaus' *Life of T.* (1871), Eadie's *History of the English Bible* (1876), and *Athenæum*, 1877 and 1878.

Tyn'dall, John, D.C.L., LL.D., F.R.S., a distinguished scientist, was born at Leighton Bridge, near Carlow, Ireland, August 21, 1820. In 1839 he acted as civil assistant to a division of the Irish ordnance survey, was then transferred to the English branch, which he quitted in 1844, and filled the position of a railway engineer for the next three years. In 1847-48, as teacher of physics in Queenswood College, Hampshire, he met Dr. Frankland the chemist, with whom he visited Germany.

At Marburg he attended the lectures of Bunsen, Gerling, Knoblauch, and Stegmann; and in the physical laboratory of Knoblauch made important researches into the magneto-optic properties of crystals, published in the *Philosophical Magazine* in 1850. Soon after his return home he was elected a fellow of the Royal Society, and in 1853 was appointed professor of natural philosophy at the Royal Institution, of which he became superintendent in 1867. In 1872 he made a lecturing tour through the United States, and placed the profits (nearly £3000) in the hands of an American committee for aiding students 'who devote themselves to original research.' In 1874, as President of the British Association, he delivered an address which roused much controversy by reason of its avowed materialistic sympathies. Besides his discoveries in magnetism and diamagnetism, his principal original researches are those on radiation (1859), which formed the subject of his 'Rede Lecture' in 1865, and on the acoustic properties of the atmosphere (1874). His great reputation rests upon his peculiar ability as a popular exponent of physical science, in which as an eloquent and lucid lecturer he occupies a wholly unique position. As an Alpine traveller he has had much experience, and his observations have fully corroborated the earlier results of Forbes relating to glacier motion, though his theory cannot be accepted as a complete scientific explanation of the phenomena. (See GLACIERS.) His own Alpine experiences are recorded in *The Glaciers of the Alps* (1860), *Mountaineering* (1861), *A Vacation Tour* (1862), and *Hours of Exercise in the Alps* (1870). He has published also a number of popular scientific works, remarkable for their clear and eloquent English, but not equally remarkable for their scientific accuracy. Of these the best known are *Heat considered as a Mode of Motion* (1863), *Sound* (1867, 3d ed. 1875), *Researches in Diamagnetism and Crystalline Action* (1870), *Notes on Electricity* (1870), *Notes on Light* (1871), *Essays on the Use and Limit of the Imagination in Science* (1871), *Fragments of Science for Unscientific People* (1871, new ed. 1876), *The Forms of Water* (1872), *Contributions to Molecular Science in the Domain of Radiant Heat* (1872). He is also author of a semi-biographical work entitled *Faraday as a Discoverer* (1868). In 1876 T. married Louisa, eldest daughter of Lord and Lady Claud Hamilton, and niece of Lord Abercorn.

Tyne, an important river in the north of England, is formed 2 miles above Hexham by the confluence of the North T. and South T., the former rising in the Cheviots on the Scottish border, 11 miles S.E. of Hawick, and traversing Keelder Moor, the latter springing from Cross Fell in Westmoreland, 11 miles N. of Appleby. The basins of both head-streams are pregnant with Border reminiscence, and are dotted with old castles and modern seats. The Reed, a feeder of the North T., has its source on Carter Fell, and flows past Otterburn; the chief branch of the South T. is the Allen, which joins it below Haltwhistle. From Hexham the T. flows E. through a richly-wooded, highly-cultivated country, passing Corbridge, Ovingham, Newburn, Ryton, Blaydon, Newcastle, and Gateshead, Walker, Jarrow, and N. and S. Shields, entering the North Sea at Tynemouth after a course of 80 miles. Above Ryton it becomes the boundary between Northumberland and Durham, and below it receives its chief affluents the Derwent and Team. The T. is navigable to Blaydon for small craft, and is crossed by many remarkable bridges. It is chiefly important as the channel of the great Newcastle coal trade, but is also the most productive of the English salmon rivers. The recent use of hang-nets at the mouth reduced the yield from 129,000 fish in 1872 to 21,746 in 1874, but certain restrictions having been placed by the conservators on net-fishing, the catch rose to 23,290 in 1875, to 24,840 in 1876, and to 41,200 in 1877.

Tyne'mouth, a watering-place of Northumberland immediately E. of N. Shields (q. v.), and 8 miles E. of Newcastle. It is an excellent bathing place, with fine sands. The new solid stone pier which shelters the mouth of the Tyne is one of the largest works of the kind ever erected in England by private enterprise. An aquarium, second only to that of Brighton, was opened in 1878. It cost £100,000. The ward or township of T. had a pop. (1871) of 21,908, but this includes much more than the village of T.

Type (Gr. *typos*, orig. 'a blow') in the New Testament means (1) a mark, as from a blow (John xx. 25); (2) a copy or image (Acts vii. 43); (3) a mould (Rom. vi. 17); (4) a model (Acts. vii. 44, Heb. viii. 5); and (5) an example (Phil. iii. 17). In theology, T. means 'some object, whether office, institution, person, or action, by means of which some truth connected with Christianity was pre-figuratively foretold under preceding dispensations.' Such an object, which in the New Testament is called a shadow (*cf.* Heb. x. i), became a T. 'because it presented the model, or representation, of something yet future.' See Fairbairn's *Typology of Scripture* (2 vols. 1870).

Types. The development of the modern atomic theory in chemistry has led to the recognition of resemblances in the constitution of different compounds and in the manner in which they react with other agents in giving rise to new products, which are likewise capable of similar comparison. Such substances are said to be modelled upon the same type; and it is found that all known bodies can be so classified in a certain limited number of groups, according to their constitution and modes of transformation. For instance, water (HOH) is capable of exchanging its oxygen and hydrogen for equivalents of other elements and groups of elements, and the resulting compounds, retaining more or less perfectly the same chemical constitution and deportment, are said to belong to the water-type. Such are sulphuretted hydrogen (HSH), caustic potash (KOH), caustic soda (NaOH), hypochlorous acid (ClOH), common alcohol (C_2H_5OH), and indeed all the alcohols. Water itself may be regarded as belonging to the hydrochloric acid type (HCl), the chlorine being replaced by the radical hydroxyl (OH); while hydrochloric acid may be referred to the hydrogen type, the simplest form of all T. (HH). Ammonia and marsh gas are also often referred to as T.; and indeed it is obvious that for special purposes any list of bodies may be chosen as T., to which all others may be referred. The regularity with which natural laws work leads us to expect a certain uniformity in combination; and perhaps when the decomposition of the elements, already rendered highly probable by the spectroscopic researches of Lockyer, has been more fully studied, simpler and more general T. may offer themselves to the theoretical chemist. Meanwhile, analogy should not be carried too far; and reasoning from type relations must ever be conducted with caution.

Types and Type'-founding. In the article Printing (q. v.) it has been shown that the early printers were generally their own typefounders, but how they did this is matter of conjecture. It is thought, however, that at first their types were cut in wood or soft metal, and that with the pattern thus cut they formed moulds in sand or other suitable material, from which they cast their types. Schœffer is believed to have been the first to devise the matrix, on very much the same principle in which it now exists. The earliest notice of typefounding in Britain is found in Archbishop Parker's preface to the *Chronicles of King Alfred*, printed in 1567 by John Daye, which states that printer to have been the first to cast Saxon types in England, though it is far from probable he was the first typefounder in the country. A decree of the Star Chamber in 1637 shows that at this date the process had become a distinct trade, as the decree limited the number of founders to four. From early times till the present century, the matrix and hand-mould of Schœffer received but slight improvement, consisting chiefly in the addition of a small lever which enabled the work to be more rapidly performed, and this matrix is still partially in use. The metal used is a compound of lead, tin, and antimony, the proportions varying with each particular founder. There are many varieties and sizes of type, but those generally in use for book-work, graduating downwards, are—English (1), Pica (2), Small Pica (3), Long Primer (4), Bourgeois (5), Brevier (6), Minion (7), Emerald (8), Nonpareil (9), Ruby (10), Pearl (11), Diamond (12), and Brilliant (13)—the latter six being seldom used but for Bibles and Prayer-Books, or as footnotes to the larger sizes. Their proportions will be better seen from the following:—

a	a	a	a	a	a	a	a	a	a	a	a	a
(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)	(12)	(13)

Pica is the standard of measurement used by printers, and is nearly one-eighth of an inch in width—nonpareil is half pica. An assortment of types of one kind is termed a Fount, to which a proportionate amount of each separate letter is given, according

to its frequency in use—thus of *e* will be given three times the quantity of *d*; of *a*, *i*, *o*, and *s*, two-thirds of *e*; of *r* one-half; of *u* one-fourth; of *v* one-tenth, of *z* one-sixtieth, and so on. Having determined the style of letter to be cast, the first operation is the cutting of the punch or die, which is done on softened steel. The cutter having satisfied himself that the letter is nearly perfect, smokes it in a lighted candle, and by an impression on paper sees where any little improvement can be made, either by a corner to be rounded off, or a round to be sharpened. The punch is next hardened and tempered, when an operator termed the 'justifier' strikes it into a piece of copper the required size, and from this 'strike' produces a finished matrix, which he so trims and 'justifies' that when placed in the mould the types cast from it shall be regular in height and appearance with all the other types produced from the punches belonging to the same fount, there being in all upwards of 350 different punches and corresponding types in one complete fount of roman and italic. This process involves considerable labour and nice technical skill. The mould into which the matrix is put is made of steel enclosed within a wooden shell composed of two halves, and adjustable to a thick and thin letter of the same fount. The matrix is firmly held in its place by a strong spring, the two halves of the mould being tied together by string, while at the top is a small opening into which the metal is poured. As the metal is run into the orifice by a small, toy-looking ladle, the mould is jerked upwards by the workman, which serves to throw the metal down into the matrix, and gives a firm, solid face to the type, assisted in this by what is known as the 'break,' a useless tag of metal which adheres to the type at the opening where the metal is poured in. The spring is then loosened, and the type drops out. This process is done with great rapidity, averaging from 600 to 800 per hour, according to the size of the type. As they leave the mould, the types are taken up by a boy, who breaks off the tag, and they are then taken by the 'rubber,' who passes them up and down a file till they are quite smooth. They are next set up in a long line on sticks about a yard long, and passed to the 'dresser,' who turns the types face downwards in blocks prepared for the purpose, and with a small plane cuts a groove in the feet of the types, removing in this way any unevenness, and enabling them to stand properly. Notches or nicks are also ploughed on the front of the type, so as to show the compositor how to place them when setting up. These nicks vary in all founts, no two founts having the same nick or series of nicks. Taken out of the blocks, a file is lightly passed along the back and front; a few types are then removed from the ends and middle of the line, and tested by various standards of steel for body, for height, and for evenness of appearance. After examination of the face through a magnifying glass, when any defective letters are thrown out, the types are finally passed as correct, and are then put into pages of separate letters ready for the printers. Letters which overlap their neighbours, such as *f* and *j*, are dressed on a specially prepared file, as the same treatment as the others would remove a portion of the letter. Types of large size with fine lines are turned out by a method of pump-casting, invented by Mr. David Bruce of New York in 1834—the ladle in this process being superseded by a small pump placed in the metal-pot, to the mouth of which the mould is held; the handle of the pump is jerked downwards, which forces the metal with considerable power into the matrix, and gives a good face, but not nearly so solid as by hand-casting. From this pump process was developed the type-casting machine, also by Mr. Bruce, and first introduced into Great Britain by Messrs. Millar & Richard of Edinburgh, who also improved upon it. With this machine the opening and closing of the mould, the advancing of the nipple of the pump, and the jerking of the handle, are done automatically—the matrix being, as in hand-casting, held in its place by the spring. On the return of the mould from the pump, it opens and lets fall a type with break attached, and it is then dressed in the usual way. Types are cast by this machine at the rate of from 100 to 120 per minute. The latest improvements upon this have been the work of Messrs. Johnson & Atkinson, by whose machine the type is not only cast, but also rubbed, dressed, and rendered almost fit for immediate use by the printer. Attempts have been made to produce types by casting several at once, like combs, of which the separate letters would form the teeth, but that nicety and accuracy which is necessary was not attainable.

Ty'pha (Gr. 'a fern') is the typical genus of *Typhaceæ*, an order of marsh or aquatic herbs with creeping root-stock, narrow linear leaves, and monœcious flowers in cylindrical spikes or heads. T., or the reed-mace, or cat's tail, and locally the bulrush—is distinguished from *Sparganium* (or bur-reed), the only other genus, by having the flowers arranged in cylindric spikes instead of globose heads. *T.* includes eight species distributed through various temperate and tropical countries. Of these *T. latifolia* and *T. angustifolia* occur in Britain by the sides of lakes, pools, rivers, and water-courses. The rootstocks have been used as food in times of scarcity, and the copious pollen is made into bread in parts of India and New Zealand.

Typha latifolia.

Ty'phon, the Greek name of the Egyptian deity Set, brother and destroyer of Osiris, who, worshipped as early at least as the sixth dynasty, came afterwards to be looked upon as an embodiment of the principle of evil. In Greek mythology T. or Typhoeus was one of the giants whom Zeus, having vanquished, placed beneath Mount Ætna.

Typhoon' (Chinese *tei-fun*, 'hot wind'), the name given to the violent hurricanes which rage on the coasts of Japan and China and the neighbouring archipelago. They occur from May to November, but especially in July, August, and September, travelling generally from E.N.E. to W.S.W. along the coast of China. In their broad characteristics they resemble hurricanes in other parts of the world, and their tremendous fury is no doubt due very much to the surface conditions under which they are produced. See WINDS.

Ty'phus Fever has been known under a number of synonyms, such as *Spotted Fever*, *Epidemic* or *Contagious Fever*, *Putrid* or *Malignant Fever*, *Camp* or *Jail Fever*, *Ship Fever*, *Petechial Typhus*, *Brain Fever*, *Irish Ague*, &c. The symptoms are thus described by Dr. Murchison: 'There is more or less sudden invasion, marked by rigors or chilliness, frequent compressible pulse, tongue furred and ultimately dry and brown, bowels in most cases constipated, skin warm and dry, a rubeoloid rash appearing between the fourth and seventh days, the spots never appearing in successive crops, at first slightly elevated and disappearing on pressure, but after the second day persistent and often becoming converted into true petechiæ, great and early prostration, heavy flushed countenance, injected conjunctivæ, wakefulness and obtuseness of the mental faculties, followed at the end of the first week by delirium, which is sometimes acute and noisy, but oftener low and wandering, tendency to stupor and coma, tremor, subsultus, and involuntary evacuations with contracted pupils. Duration of the fever from ten to twenty-one days, usually fourteen. In the dead no specific lesion, but hyperæmia of all the internal organs, softening and disintegration of the heart and voluntary muscles, hypostatic congestion of the lungs, atrophy of the brain, and œdema of the pia-mater, are common.' The phenomena of T. F. depend upon the absorption into the system of a specific poison, and the period of incubation is from one to twelve days. Should a fatal termination ensue, it usually happens between the twelfth and twentieth day of the fever, death being preceded by great prostration, involuntary evacuations, and coma. The mortality is about one in five of those attacked, and the greater the age above ten years the greater the danger.

T. F. is distinguished from any inflammatory condition of the lungs by the peculiar rash and the nature of the fever, from acute meningitis by the peculiar rash and the absence of nausea, vomiting, and delirium, almost from the commencement, which characterise meningitis. Professor Charteris draws the following distinctions between T. F. and Typhoid or Enteric Fever (q. v.). '(1) In T. F. the rash is mulberry, mottled, and continuous, going on to ecchymosis, and hence resisting pressure; in typhoid the rash consists of rose-coloured spots, fading in three

days, and giving place to a fresh crop: these spots disappear on pressure, and are not surrounded by mottled skin. (2) In T. F. the rash appears from the fifth to the eighth day; in typhoid fever between the seventh and the fourteenth. (3) In T. F. there is no diarrhœa; in typhoid, diarrhœa is common, and the stools are of a peasoup colour. (4) In T. F. the symptoms are generally cerebral, hence disquietude going on to coma, with an intermediate stage of delirium; in typhoid the symptoms are abdominal, hence diarrhœa and pain on pressure over the right iliac fossa. In T. F. we see contracted pupils, mutterings, delirium preceded by disquietude and uneasy manner, and congested conjunctivæ; in typhoid we see dilated pupils, delirium preceded by apathy and somnolence, and no congestion of the conjunctivæ. (5) These fevers also differ in their duration, a crisis being reached in T. F. on the fourteenth day of the fever; while in typhoid not a crisis but a lysis is reached on the twenty-first day. T. F. may occur at any age, and is commonest among the poor. Typhoid is generally a disease of youth or of adult life, is rare after forty, and it shows no partiality to the poor.'

T. F. was one of the early pestilences and plagues; and under the term Typhus the writer of one of the Hippocratic treatises describes a disease resembling typhoid fever. Sauvages, in his *Nosology*, was the first to use the term in designating certain forms of continued fever. It has generally prevailed as an epidemic where insanitary conditions, overcrowding, and famine have prevailed. In 1487 Ferdinand lost 17,000 of his soldiers from T. F.; and, in 1552, Karl V. lost a large number of his men at the siege of Metz. In 1566 T. F. appeared in the army of Maximilian II., and spread over the whole of Europe. During the Thirty Years' War it was prevalent in Central Europe, and the Bavarian army lost in Bohemia 20,000 men. In the wars of Louis XIV., Friedrich the Great, Napoleon I., and lastly, in the Crimean War, it prevailed to an alarming extent. In former times T. F. was exceedingly common in the prisons of Europe, and was called *jail fever* or *distemper*. It is supposed to have been the disease communicated from the prisoners at the Black Assizes; and so late as 1815 in Dublin, 1839 at Rheims, and 1854 at Strassburg, it was present in the prisons. Ireland has been peculiarly subject to epidemics of T. F., probably from the predisposing influence of privation, the principal epidemics having occurred in 1708, 1718, 1729, 1735, 1740, 1770, 1797, 1803, 1817, 1826, and 1846. The epidemic of 1740 in Ireland, together with famine, is said to have destroyed 80,000 people; that of 1846 was still more destructive, and raged over the whole British Islands for two years. 300,000 cases were said to have occurred in England, 19,254 in Scotland, and 1,000,000 cases in Ireland, in 1847. In Liverpool alone 10,000 cases were said to have occurred, the chief force of the epidemic having fallen upon the overcrowded lodging-houses. The last considerable epidemic in England, in 1862-69, was of a partial character, its principal seat being in London.

The chief, if not the only, exciting cause of T. F. is the specific poison of the disease transmitted from person to person by contagion or fomites; but it can also be communicated apart from actual intercourse with the sick by the use of articles of bedding and clothing that have been used by patients suffering from the disease, or by residence in a house where the fever has recently existed. Dr. Buchanan states, as the result of his experience at the London Fever Hospital, that 'nurses in hospitals, where many cases of T. F. are received, invariably get T. F., no matter under what sanitary conditions they are placed. There appears to be no exception to this rule, unless, indeed, it be that the nurse is insusceptible of the disease from a previous attack of it. Medical men and Catholic priests in attendance upon numerous T. F. cases are also almost sure, sooner or later, to get T. F., and that they do not fall ill with so much certainty and rapidity as the nurses, appears due only to their contact with the sick being less constant and intimate. The contagious matter of the disease seems peculiarly capable of destruction when it is diluted with air. Thus, tolerably close communication with the body of a T. F. patient appears requisite for the reception of contagion from him. Casual visitors to fever wards very seldom get T. F., and in private houses of the better class the disease rarely spreads to the attendants. Extension of T. F. from an hospital to the adjacent streets is unknown, even though there should be hundreds of cases congregated within a very short distance of other buildings.'

T. F., like other diseases of its class, cannot be cured, in the strict sense of the term, nor can its duration be shortened by any means at present known to medical science. The only treatment consists in supporting the strength through the course of the fever, and combating symptoms and complications as they appear while the curative processes of nature are going on. The nutriment given should be such as requires the simplest processes for its assimilation, such as beef-tea, broths, milk, eggs, and, in certain cases and stages of the disease, alcoholic stimulants. A little only should be given at once, but it should be given frequently—every two or three hours; and if the patient be in a drowsy state, he should be roused up to take his nourishment. Lemonade, soda-water, and cold weak tea without sugar or milk, may be given for drinks. The cases in which alcoholic stimulants are serviceable are, '(1) in old people almost universally; (2) cases of great prostration, with low delirium and coma; (3) cases where the pulse is very compressible, and the first sound of the heart feeble, also when the pulse intermits, and usually when it exceeds 120 in frequency; (4) cases where the extremities are cold and the surface is livid; (5) where there is much congestion of the lungs; (6) where there is any erysipelatous complication' (*Buchanan*). Stimulants are contra-indicated in the majority of cases, and even in severe cases where there is violent maniacal excitement; but they are useful when the patient is approaching the crisis of the disease, in the second or third week. Combating symptoms depends, of course, on the nature and intensity of the symptoms and complications, so that during the course of the disease it may be necessary to treat the patient for delirium, constipation, diarrhœa, bronchitis, pneumonia, retention of urine, swelling and suppuration of the salivary glands, erysipelas, &c. Cold baths at about 65° F. have been strongly recommended lately, and they may be repeated, day and night, when the temperature rises above 102° F. Patients should be removed from close, crowded rooms to a properly constructed hospital. Quiet, cleanliness, frequent sponging, and change of position, to avoid congestion of the lungs and bed-sores, are necessary, but above all there should be an ample supply of fresh air of even temperature, and the attention of an experienced nurse.

The prevention of the spread of the disease is a matter of great public importance, and this is best attained by free ventilation, for, even without disinfectants, free dilution destroys the poison or renders it inert. The breath and cutaneous exhalations of the patient being the principal vehicles of infection, the patient should be placed in the highest room of a house or hospital. The body should be anointed with olive-oil mixed with a little carbolic acid, and the excreta should be disinfected with a solution of sulphate of iron. After recovery or death, the room should be fumigated with nitrous-acid fumes, and the bedding and clothes should be burned, or thoroughly baked and washed. See Ziemssen's *Cyclopædia of the Practice of Medicine* (vol. i. 1874), Reynolds' *System of Medicine* (vol. i.), *A Treatise on Continued Fevers*, by Dr. Murchison (Lond. 1873).

Tyr (Old Eng. *Tiw*, O. H. G. *Ziu*), in the northern mythology a son of Odin and Frigg, is the god of war and the sword. He alone of all the Æsir had the courage to bind the ferocious Fenrir-wolf, in doing which he lost his own hand. In the 'twilight of the Æsir' he fights with the hell-hound Garmr, and both are slain. See TUESDAY.

Ty'rant (Gr. *tyrannos*, prob. connected with *kurios*, 'lord') originally meant among the Greeks one who had usurped power at the expense of the existing forms of government. Most of the Greek states were close oligarchies, and it frequently happened that some one member of the aristocracy would succeed either by means of foreign mercenaries or by allying himself with a popular party in ousting the government of the day and setting himself at the head of the state. Such a ruler was of necessity distasteful to the nobles, but might be acceptable to the body of the people; nor did the irresponsibility of his position necessarily lead him to prejudice his popularity by acts of oppression or violence. The 'tyranny' of Peisistratos was mild, humane, and beneficent. The *Thirty Tyrants* is the name given to the government set up by Sparta in Athens at the end of the Peloponnesian War, B.C. 404. See besides the histories of Greece, Plasz, *Die Tyrannen* (Bremen 1852).

Ty'rant Shrike', King Bird, or Ty'rant Fly'catcher, the *Tyrannus intrepidus* of ornithologists, is an *Insessorial* bird,

named from its bold and wary habits, and from its pugnacious disposition. It is found in America, attains a length of 8 inches, and is black and ashen grey above, and white below, a grey patch occurring on the breast. From the golden feathers of its crest, it has been named the 'King Bird.' Its food consists of insects and berries. The T. S. is of migratory habits, and arrives in the United States in April.

Tyrconn'el, Richard Talbot, Earl of, born in Ireland in 1625, was in early life noted for his unscrupulous character, came to England at the Restoration, but was banished in 1677 for a conspiracy against Charles II. He was created by James II., on his accession, Earl of T., and was in 1686 made commander of the forces in Ireland. In January 1687 he succeeded Clarendon as Lord-Lieutenant, when he commenced a policy which in a few months completely overthrew the English ascendancy, every Protestant judge and magistrate being replaced by an Irish Catholic, and the army being completely purged of its Protestant officers and men, while several new regiments were formed of the most ignorant and bigoted recruits. When the Revolution took place, T., to gain time for maturing his plans, intrigued with William for two months, but at the beginning of 1689 hoisted a flag, embroidered with the words 'Now or Never,' from Dublin Castle, and in a short time had an army of 50,000 men. After the defeat on the Boyne, T. went to France, returned with French forces in the spring of 1691, but died at Limerick, July 14th, 1691. T. was married to Frances Jennings, a sister of the famous Duchess of Marlborough. His name was execrated in England, and is celebrated in the famous contemporary doggrel ballad *Lilli Burlero*, which 'whistled a deluded prince out of three kingdoms.'

Tyre (Heb. *Sôr*), the most powerful and, with the exception of Zidon, the most celebrated city of Phœnicia, was built partly on the mainland and partly on an island 33 miles N.N.E. of Carmel and about 47 S.W. of the modern Beirût. T. first appears in history as the kingdom of Hiram the friend of David and Solomon (10th c. B.C.), by whom the island is said to have been first occupied and united with the mainland by moles nearly 4000 feet long, forming a spacious and secure harbour. As this island was only some 22 stadia in circumference, the houses were built unusually high—five or six stories; the most important building was a temple of Melkart. From the time of Hiram T. increased rapidly in importance, trading not only with the Mediterranean countries, but even with Britain and Gaul, exporting largely home manufactures, especially the celebrated Tyrian purple. T. endured several severe sieges, in which the island frequently held out long after the reduction of the part situated on the mainland, from Salmanassar (8th c. B.C.) for five years; Nebuchadnezzar (580 B.C.) for thirteen years, and unsuccessfully as regards the island; from Alexander the Great (332) for seven months by land and sea; from Antigonus (314) for fourteen months. Notwithstanding these repeated disasters, the unusually favourable position of T. enabled it to recover itself with surprising rapidity, and under the Romans it was a place of wealth and importance, and continued a formidable stronghold down to the time of the Crusades. Taken by the Saracens in 1191 A.D., T. rapidly sank, and the opening of the sea route to India gave the final blow to its greatness. The causeway constructed by Alexander in his siege has almost completely silted up the harbour, so that what was formerly an island is now a peninsula. The modern Sûr has about 5000 inhabitants, of whom half are Christians. The only interesting building remaining is the *Crusaders' Church* of the 12th c.

Tyr'nau (Hungar. *Nagy-Szombat*), a town in the comitat of Pressburg, Hungary, on the Trnawa, 28 miles N.E. of Pressburg by rail. It has a cathedral founded in 1389, and many other churches. Boulevards surround the town. There are cloth, linen, and sugar manufactures, as well as trade in agricultural produce and wine. A university founded here in 1635 was transferred to Pesth in 1784. T. has a great vat, larger than that of Heidelberg, and holding 27,000 gallons. Pop. (1869) 9737.

Tyr'ol (properly *Tirol*), the most westerly crown-land of Austria, is bounded N. by Bavaria, S. by Italy, W. by Switzerland and Lichtenstein, and E. by the crown-lands of Salzburg and Carinthia. Area, with Vorarlberg, 11,323 sq. miles; pop. (1870) 885,789. T. is a singular survival of an ancient type among the discordant elements of modern Europe. The people of the Zillerthal, the typical Tirolese, are pre-eminently distinguished by their national music, their deep attachment to their old religion, their picturesque costumes, and their passion for athletic exercises. Geographically T. resembles Switzerland; it is traversed by the N., Central, and S. Alps, and is divided mainly into three valleys, two of which, watered by the Inn and the upper streams of the Adige or Etsch, run from E. to W., while the third trends in a S. direction and forms a course for the main stream of the Adige. Outlying portions are the Vorarlberg, a district on Lake Constance, and the Leinz district on the Drave. The highest summits are the Ortler Spitze (12,814 feet), the Gross Glockner (12,405), the corner-stone of T., Salzburg and Carinthia; Wild Spitze (12,390), and Marmolata (11,045), the culminating point of the Dolomite district, on the Italian frontier. The Dolomites, formed of magnesian limestone (a rock named after the geologist M. Dolomieu), attract many tourists on account of their grand, fantastic outlines, and the weird splendour with which they are lit up at sunset, when their crests take the semblance of transparency. The principal rocks of T. are crystalline, Silurian, and Secondary, irrupted with trap and granite. There are 123 mineral wells, of which the most celebrated are at Rabbi, Antholz, Prax, and Obladis. The mining industry has lost its former importance, but there is still a slight yield of copper, iron, lead, silver, zinc, salt, marble, granite, &c. The mountains, which send down vast glaciers, are in many places clad with beeches to an elevation of 4000 feet, and beyond that by fir-woods. Of the surface only a small portion is cultivated, and that by clumsy methods. Next to the Etschthal the most productive parts are the Vorarlberg and the Zillerthal. In 1876 T. produced 250,000 hectolitres of wheat, 455,000 of rye, 175,000 of barley, 150,000 of corn, 480,000 of maize, 125,000 of buckwheat, and 1,060,000 of potatoes, besides some hemp, flax, tobacco, and chicory. In the S., where much fine fruit is cultivated, the yield of wine was 320,000 hectolitres in 1876 (586,000 in 1875). Cattle-rearing and dairy-farming are the chief occupations, and in 1870 there were in T. 402,152 cattle, 309,428 sheep, 121,997 goats, and 47,899 swine. The industries centre in Innsbruck, the chief town, Trent and Botzen. The Brenner railway, connecting the lines at Innsbruck and Botzen, crosses the Brenner Pass (4657 feet). Ethnographically the country is divided into German and Italian T., the inhabitants of the former being three times more numerous than those of the latter. A few miles above Trent there still stand two villages on opposite sides of an affluent of the Adige, the northern called Mezzo Tedesco or 'German Limit,' the southern Mezzo Lombardo or 'Italian Limit.' The Tyrolese are almost all Roman Catholics, and there are 2300 priests and 87 convents, with 1123 monks and 1162 nuns. Education is widely spread, and Innsbrück has a university; yet T., with its striking natural phenomena, its crosses, chapels, and religious symbols, is a land of ancient legend and modern superstition. An independent national diet meets at Innsbruck. Originally part of Rhætia, T. was conquered by the Romans and overrun by German tribes. Christianity was introduced as early as the 4th c. The northern valleys fell subsequently to the Bavarians, and were divided into *gaus*, which, after existing as petty lordships, were united by one family of counts, whose residence, the Schloss T., near Meran, gave its name to the whole country. Margarethe Maultasch, daughter of the last count, bequeathed her rights to her cousins, the dukes of Austria, who thus acquired T. in 1363. The S. valley, which had been seized by the Lombards, was formed into the diocese of Trent. By the peace of Pressburg (1806) T. was ceded to Bavaria; but the inhabitants were attached to the House of Hapsburg, to whose rule they were restored in 1814 (see HOFER, ANDREAS). The representatives of Italian T., or Wälsch-T., withdrew from the national diet in 1877, their demand for autonomy having received a decided check. There is, indeed, little chance of southern T. being joined to Italy. See Egger, *Geschichte Tirols* (Innsb. 1870 *et seq.*); and, for a sketch of the folklore, Miss R. H. Busk, *The Valleys of T.* (Lond. 1874).

Tyroliene', a song accompanied with dancing, originally a Tyrolese melody. The T. introduced by Rossini in *William Tell* was the first of the kind which was not a Volkslied.

Tyrone' (Irish Gael. *Tir-Eoghain*, 'Owen's territory'), an inland county of Ulster, Ireland, is bounded N.E. by

Londonderry, E. by Lough Neagh and Armagh, S. and S.W. by Monaghan and Fermanagh, and N.W. by Donegal. Area, 806,658 acres; pop. (1871) 215.766, of whom 119,937 were Roman Catholics, 49,201 Protestant Episcopalians, and 42,156 Presbyterians. The surface is hilly, being traversed to the N. by offshoots of the Donegal and Londonderry ranges, and of Monaghan and Fermanagh to the S., and the principal elevations are Slieve Sawel (2236 feet), Mullagh Clogher (2083 feet), and Oughtdoorish (1866 feet). The Blackwater, Ballinderry, and Camoan are the principal rivers, and with Lough Neagh (q. v.) and other smaller lakes and streams give a total water area of 31,043 acres. The soil of the central plain, overlying Tertiary and Old Red Sandstone formations, is a fertile loam, and the climate is moist, the rainfall of 1877 being 49·55 inches. Of 258,150 acres under crops in 1878, 1673 were in wheat, 112,614 in oats, 543 in barley, bere, and rye, 43,579 in potatoes, 16,908 in turnips, 18,475 in flax, and 60,220 in meadow and clover, and plantation covered 9777 acres in 1877. T. had (1878) 26,510 horses and mules, 1064 asses, 159,858 cattle, 46,083 sheep, and 38,105 pigs, while the valuation amounted to £434,015. Agriculture is the staple industry, but there are numerous flax-scutching mills, besides manufactures of linens, woollens, pottery, whisky, &c., and eleven collieries, which with one Antrim pit yielded 15,398 tons in 1877. Emigration has drained off one-third of the population since 1851, 84,613 persons having left the county up to December 31, 1877. Omagh (q. v.), Dungannon (q. v.), and Strabane (q. v.), are the chief places of T., which return two members to Parliament. In the earliest historic times T. was possessed by the Kinel Owen, a branch of the northern Hy Neill.

Tyrrhe'nian Sea (anc. *Tyrrhenum Mare*, and *Mare Tuscum*), the part of the Mediterranean Sea between the W. coast of Italy and the islands of Corsica, Sardinia, and Sicily.

Tyrtae'us, an ancient Greek poet who flourished at Sparta during the second Messenian War (685-665 B.C.). The tradition is that the Spartans being hard pressed by their foes consulted the oracle, who responded that a leader must be sought from Athens. This was done, but the Athenians, glad to play a sort of practical joke on the embassy, gave them a lame schoolmaster. The Spartans received the dubious gift with simple faith, and it was soon found that their trust was not ill placed. Their new leader proved a mighty genius, and especially a great poet. His songs in praise of the Spartan Constitution quelled discontent at home, whilst his martial odes inspired the soldiers in the field to victory. His poems were of three kinds, (1) martial exhortations, (2) political odes, (3) war marches. The fragments we possess are distinguished by a fine military fervour. The best edition is by Bach (Leips. 1831).

Tyr'whitt, Thomas, son of Dr. T., canon of Windsor, was born in London, 29th March 1730, educated at Eton and Queen's College, Oxford, and elected to a fellowship at Merton. He was Clerk of the House of Commons (1761-67), was appointed curator of the British Museum (1784), and died 15th August 1786. Besides several treatises on classical subjects, T. wrote *Observations on Some Passages in Shakespeare*, *The Canterbury Tales of Chaucer* (1775-78), and *Poems supposed to have been written at Bristol in the 15th c. by Rowley and others, with a Preface and Glossary*, to which he added an appendix proving that Chatterton was the author. T. merits remembrance mainly for his services as an editor of Chaucer. He was the first who sought to expel from the biography of the poet everything that did not rest on documentary evidence; his collation of the Chaucerian MSS., though not particularly discriminating, was extremely laborious; his arrangement of the 'Tales' is excellent; and his 'Dissertation' and 'Notes,' with all their linguistic imperfections, are of great and enduring value for the interpretation and illustration of the 'Father of English Poetry.'

Tyt'ler, William, a Scottish historian and antiquary, was born in Edinburgh, October 12, 1711, educated at the High School and University of his native city, and in 1744 was admitted to the Society of Writers to the Signet. He died September 12, 1792. T. wrote several valuable works, among others *A Historical and Critical Inquiry into the Evidence produced against Mary, Queen of Scots* (1759; 4th ed. 1790), in which he warmly espouses the cause of the unfortunate princess, *The Poetical Works of James I. of Scotland* (1783), to which he prefixed a dissertation on the life and writings of the royal bard, and *A Dissertation on Scottish Music*, which first appeared as an appendix to Arnot's *History of Edinburgh*. See Henry Mackenzie's *Account of the Life and Writings of Willam T. of Woodhouselee*.—**Alexander Fraser T., Lord Woodhouselee**, son of the preceding, was born at Edinburgh, Oct. 15, 1747, entered the High School in his eighth year, and left dux of the rector's class. After spending two years at an academy in Kensington, where he assiduously cultivated the accomplishment of Latin verse, he went in 1765 to the University of Edinburgh, and passed advocate at the Scotch bar in 1770. In 1786 he became Professor of Civil History, in 1790 Judge-Advocate of Scotland, and in 1802 was raised to the bench, when he took the title of Lord Woodhouselee, from an estate near Edinburgh belonging to his father. He died January 5, 1813. T. was one of the most scholarly lawyers and litterateurs of his age. His chief writings are *The Decisions of the Court of Session from its first Institution to the present Time* (Edinb. 1778), *Plan and Outline of a Course of Lectures on Universal History, Ancient and Modern* (Edinb. 1783; the *Lectures* themselves were not published till 1834-35), *Elements of General History, &c.* (Edinb. 1801), a work that was long remarkably popular, and *Memoirs of the Life and Writings of the Hon. Henry Home of Kames, containing Sketches of the Progress of Literature and General Improvement in Scotland during the greater part of the Eighteenth Century* (Edinb. 1807).—**Patrick Fraser T.**, youngest son of the preceding, was born at Edinburgh, 30th August 1791, educated at the High School and University of Edinburgh, and passed advocate at the Scotch bar in 1813. For some years he held the office of King's Counsel in Exchequer. In 1819 he first appeared as an independent author by the publication of a *Life of James Crichton of Cluny, commonly called the Admirable Chrichton* (1819; 2d ed. 1823), a work of great care and labour, and marked by much original research. It was followed in 1823 by *An Account of the Life and Writings of Sir Thomas Craig of Riccarton, including Biographical Sketches of the most eminent Legal Characters, from the institution of the Court of Session by James V. till the period of the Union of the Crowns*. In 1826 he published anonymously a *Life of John Wickliffe*. But his *magnum opus* was his *History of Scotland*, undertaken by the advice of Sir Walter Scott. It extended to 9 vols., of which the first appeared in 1828 and the last in 1843. It opens with the accession of Alexander III. in 1249, and closes with the accession of James VI. to the throne of England in 1603. T.'s history is a work of great and genuine erudition; and though criticism has made havoc of some of his authorities, *e.g.* the so-called 'Fordun,' and introduced into the discussion of disputed questions considerations unknown to T., its essential value has not been impaired. The author has been surpassed, but not superseded, by Hill Burton. While occupied with the composition of his chief work T. wrote several historical biographies of considerable merit, of which the most important is his *Lives of Scottish Worthies* (3 vols.) and his *Life of Sir Walter Raleigh* (1832). T. died at Great Malvern, Worcestershire, 24th December 1849. See the Rev. John Burgon's *Memoir of P. F. T.* (Lond. 1859). There is also a shorter sketch by John Small, prefixed to a recent edition of the *History of Scotland*.

Tzetz'es, Johannes, Greek poet and grammarian, was born about 1120 A.D. at Constantinople, and died about 1183. His *Chiliades*, a collection of 30,000 'political iambics,' whose theme is stories drawn from Greek history and mythology, has been edited by Kiessling (Leip. 1826); his *Iliaca*, a résumé of Homer's *Iliad* and kindred poems, by Bekker (Berl. 1816). Worthless as literary productions, these yet contain a large store of valuable matter that otherwise had perished. Commentaries on Homer, Hesiod, the *Plutus* of Aristophanes, and Lycophron's *Alexandra* (ed. by Müller, 3 vols. Leip. 1811), make up the remaining works of T.

U.

the twenty-first letter of the English alphabet, and the last of the true vowel sounds. In the Semitic alphabet it does not exist, and in both Greek and Latin its character was confused with that of the cognate consonant V. Its proper phonetic value is that heard in 'full,' but more commonly expressed by 'oo.' Its two remaining sounds in English, that in 'mud' and that in 'union,' are both of them anomalous and almost peculiar to our language. The former sound is really that of a short A. The latter sound, which is the commonest of the three, is really YU, and may be paralleled by the fact that the Greek U, or Hypsilon, is always aspirated at the beginning of a word. The modified German U, ü or ue, is a peculiar sound that ought not to be difficult to Scotchmen or Devonshire men; it is also found in French as 'eu.' In modern Greek, U is pronounced as simple I. In transliteration from the Greek, most modern languages follow the Latin in substituting Y for U; as 'hyacinth.' As a diphthong, U sometimes reverts to the pronunciation of the original V, as is the case with 'au' and 'eu' in modern Greek, and sometimes has the peculiar sound of 'ow,' as with Ger. 'au,' Eng. 'ou,' and Dutch 'ui.' U most frequently interchanges with O: as Gr. *theos* = Lat. *deus;* Lat. *uncia* = Span. *onza*, and our 'ounce;' Lat. *lupus* = Fr. *loup*.

Ube'da, a town of Spain, province of Jaen, on a fertile plateau about 2000 feet above the sea, between the rivers Guadalquivir and Guadalimar. It has a castle, several churches, monasteries and other large buildings; and trades in cloth, leather, wine, and oil. Pop. 18,378. The Moorish king, Mohammed, surrendered here in 1210 to the allied kings of Navarre and Castile.

Ucay'ale, or **Ucay'ali,** a great river of Eastern Peru, and one of the main affluents of the Amazon, of which it was formerly regarded as the head-stream. This honour is now accorded, however, to the Marañon, which, though shorter than the U., is twice as broad as the latter at their confluence. The U. rises in the mountains of Southern Peru, some of its feeders having their sources only 150 miles from the Pacific on the one hand, and 100 miles from Lake Titicaca on the other. In its upper course the U. is known as the Apurimac (q. v.), and below the junction of the Mantara, in 12° S. lat., it is called the Tambo. After receiving the united waters of the Urubamba and Camisea in 9° S. lat., it becomes known as the U. Its entire course is about 1200 miles in length. The U. has been navigated by steamers for a great part of its course, and a steamer has penetrated by the Pachitea, a tributary on its left bank, to within 220 miles of Callao. The Apurimac is not navigable; but with this exception, and that of a fall on the Lower Urubamba, the U. and its principal tributaries are most valuable highways to the heart of a region abounding in vegetable and mineral wealth.

U'dal Right. See ODAL.

U'dall, Nicholas, the author of the first English comedy, was born in Hampshire about 1505 or 1506. Having received his education at Oxford, he chose the profession of a schoolmaster, and in 1534 he passed M.A. and obtained the post of headmaster of Eton, which he held till 1541, when he was dismissed. He afterwards resigned the vicarship of Braintree in Essex, which he had enjoyed along with his mastership; but he continued both to teach and preach, and in 1551 we find him admitted a prebendary of Windsor, and in 1554–55 appointed headmaster of Westminster school. He died in 1556. U.'s comedy of *Ralph Roister Doister*, which was probably written for the Eton boys, is a perfectly harmless piece, with a fair amount of vivacity in its execution and ingenuity in its plot, the hero being led into various awkward situations in the course of his suit to Dame Custance, partly by his own stupidity, and partly by the malicious suggestions of Mathew Merrygreek. The play is in rhyme, and has thirteen *dramatis personæ*. Hallam notices that the choice of a city-galiant for 'hero' probably determined in some measure the prevalent subject of English comedy all through the Elizabethan age. The exact date of its composition has not been determined; it is quoted in the 3d edition of Sir Thomas Wilson's *Rule of Reason* (1553), but *not* in the 2d edition (1552). There is but *one* copy of U.'s comedy in existence, having no title-page; but it was probably printed in 1566. It is now in the library of Eton College. Of the other productions of U.'s pen it is enough to name *Flowres for Latin Speakynge* (portions of Terence done into English, 1533), translations of part of Erasmus's Paraphrase of the New Testament, and of Peter Martyr's tract on the Eucharist, and a few Latin letters and poems. See Wilson's *Arte of Logike* (1567), Bliss's edition of Wood's *Athenæ Oxonienses*, and the preface to Arber's reprint of *Roister Doister* (1869).

Udi'ne, the chief town of a province of the same name in N. Italy, on the Roja, 75 miles N.E. of Venice by the Venice and Trieste railway. The seat of an archbishop, it is girt by old walls, and has a castle which dates from 1517, and was formerly the residence of the patriarchs of Aquileia. Its chief buildings are the Palazzo Publico (built in 1457, partly burned in 1876), the Romanesque cathedral, adorned with fine sculpture in wood and stone, and the episcopal palace. The Campo Santo is one of the finest cemeteries in Europe. There are manufactures of hats, leather, metal wares, gloves, &c., and a good trade in wine. Pop. (1876) 22,692. In the adjoining village of Passerino is the castle of the Venetian Doges, occupied by Napoleon during the negotiation of the peace of Campo Formio in 1797.

Ue'berweg, Friedrich, a German philosophical writer, born 22d January 1826, at Leichlingen in Rheinpreussen, studied philology at Göttingen under K. F. Hermann, and philosophy at Berlin under Beneke, and was successively a teacher at Elberfeld (from 1851), *privat docent* at Bonn, extraordinary (1862) and ordinary (1867) professor of philosophy at Konigsberg, where he died, June 9, 1871. His principal works are *System der Logik und Geschichte der logischen Lehren* (Bonn 1857; 4th ed. 1874; Eng. trans. by T. Lindsay, 1871), *Grundriss der Geschichte der Philosophie von Thales bis auf die Gegenwart* (3 vols. Berl. 1863–66; 5th ed. 1877; Eng. trans. by G. S. Morris, 2 vols. 1874).

U'fa, a government in E. Russia, lying W. of the Ural chain, formed in 1865 out of the N.W. part of Orenburg. Area, 47,031 sq. miles; pop. (1871) 1,364,925. It is mountainous in the E., but in the W. the surface slopes to rich plains largely covered with forests, and watered by the Bielaia, which receives the Ufa and many affluents from the Ural mountains. The soil is fertile, but only a small portion is under tillage. Rich deposits exist of iron, lead, copper, and gold, still little wrought.—**U.,** chief town of the preceding, at the junction of the U. and the Bielaia, 210 miles S. of Perm, is the seat of a Greek archbishop and a Tartar mufti, has twelve churches, several mosques, and holds every January a ten days' fair, which is much frequented. Pop. (*St. Petersb. Cal.* 1878) 20,917.

Ugan'da, a kingdom of Central Africa, extending half round the N. and W. shores of Lake Victoria Nyanza (q. v.). It is about 300 miles long and 60 miles broad, with a pop., including that of tributary tribes, estimated by Stanley at 2,775,000. The general aspect of U. is that of a rolling, wooded, fertile, and cultivated country, traversed by broad, well-made roads. Coffee

(which is chewed instead of boiled by the natives), tobacco, the sugar-cane, yams, and bananas, grow in profusion, and large herds of cattle and goats are reared. Elephants are numerous, and are hunted for their ivory. Iron is abundant in many places. The capital, Ulagalla, situated a little way inland from the lake not far from its outlet, is a large town finely laid out with straight, broad streets lined with trees, and centres in the royal quarters, which form a town in themselves, crowning an eminence and having seven broad avenues radiating from them. The chief industries are iron-working, the tanning of skins, and weaving of bark cloth. The women do all the field-work. The king, Mtesa, is very friendly to Europeans, and at his request missionaries commenced their labours at Ulagalla in 1878. See Speke's *Journal of the Discovery of the Source of the Nile* (Lond. 1864), Stanley's *Through the Dark Continent* (Lond. 1878).

Uglitch', a town of Russia, government of Jaroslav, on the right bank of the Volga, 40 miles S.W. of Rybinsk. It manufactures paper, leather, soap, copper, and tin wares, and conducts a large transit trade in timber. Pop. (*St. Petersb. Cal.* 1878) 13,069.

Uh'land, Johann Ludwig, one of the most popular poets of modern Germany, was born at Tübingen, 26th April 1787, studied at the Gymnasium and University of his birthplace, and in 1810 went to Paris ostensibly to study the Code Napoleon, but chiefly occupied himself in examining old French and German manuscripts relating to the Middle Ages. On his return to Germany he engaged in business for some time as a lawyer in Stuttgart. His ardent poetic temperament, and his deep national sympathies, caused him to take an intense interest in the German War of Liberation. U. gave expression to his country's aspirations and his own in his noble *Gedichte* (Stuttg. 1815; 60th ed. 1875), which, enriched by numerous additions, remains his greatest work. This was followed a few years afterwards by two dramas, *Ernst, Herzog von Schwaben* (Heidelb. 1818), and *Ludwig von Bayer* (Berl. 1819). His next work, *Walther von der Vogelweide* (Stuttg. 1822), showed a profound knowledge of early German history. In 1829 U. was appointed Professor of German Literature at Tübingen, but resigned his chair in 1832 for political reasons. In 1836 he published a dissertation *Ueber den Mythus vom Thor* (Stuttg.), and in 1844 a very excellent collection of old popular German ballads entitled *Alte hoch und niederdeutscher Volkslieder.* He died at Tübingen, 13th November 1862. As a poet, U. takes a foremost rank among the representatives of the Romantic school. An intensely keen and true poetic instinct enabled him to grasp the permanently beautiful and true element in some old story, and reproduce it with no charm gone in modern dress. His best poems are lyrics or ballads. In the first, some quaint fine thought is touched to some unexpected yet pleasing issue; in the other, a picture is often painted in a few suggestive words—as, for instance, in such masterpieces as *Das Schloss am Meer*, *Auf der Ueberfahrt*, and *Der Wirthlein Töchterlein.* All his poems are pure and high-toned. Their melody is exquisite, deep, and true. It vibrates long in the ear, and lingers long in the mind, like the memory of some dear possession that we let go slowly and unwillingly. U.'s prose writings, including his lectures on German literature, were edited by Keller, Halland, and Pfeiffer, under the title *Schriften zur Geschichte der Dichtung und Sage* (8 vols. Stuttg. 1866-69). See Jahn's U. (Bonn 1873); Pfeiffer, U. (Wien 1862); Natter, *Erinnerungen an U.* (Stuttg. 1863); and U.'s *Leben*, edited by his widow (Stuttg. 1874). Several of U.'s poems are exquisitely translated by Longfellow in his romance of *Hyperion.* See also translations by Skeat (Lond. 1864) and Sandars (Lond. 1869).

Uh'lans, a word of Tartar origin signifying 'brave,' which, transferred from the Tartar horsemen who harassed the Polish frontier to the Polish light cavalry raised to repel their inroads, was introduced into the Austrian service (1791), and the Prussian (1808). See CAVALRY and LANCERS.

Uist, N. and S., two of the Outer Hebrides, forming part of the shire of Inverness, Scotland, and about 15 miles W. of Skye. They lie S. of Lewis and Harris, and the island of Benbecula (q. v.) intervenes between them. N. U. is 16 miles long, and from 3 to 13 broad. Pop. (1871) 3222. The coast, especially on the E., is much indented, and excellent harbours are formed at Loch Maddy and elsewhere. The surface is mostly a boggy peat-moss with hills in the W. There are some small fields of oats and clover. The inhabitants are chiefly fishermen. S. U., longer and narrower than N. U., has a range of hills along its E. coast, of which the highest, Mount Heckla, is 2500 feet high. Loch Boisdale, on the same side, forms an excellent harbour. The W. part is somewhat fertile, and is covered with numerous lakes. The inhabitants, mostly Roman Catholic, engage chiefly in fishing. Pop. (1871) 3669.

U'jein. See OOJEIN.

U'jhély-Satoral'ya, a town of N. Hungary near the Bodrog, an affluent of the Theiss, 40½ miles S.E. of Kaschau by rail, in the vicinity of vineyards and marble quarries. Pop. (1869) 9946.

Uji'ji, a small territory on the N.E. shore of Lake Tanganyika, Central Africa. Area, 920 sq. miles; pop. 36,000. The natives are a fine-looking but drunken and dishonest race. They are good smiths and expert fishers and canoemen. The chief town of U., Kawele, in 4° 47′ S. lat., is a place of considerable trade. Besides being the terminus of the great caravan route from Zanzibar and the residence of a number of Arab traders, it has a daily market, which is largely attended by natives from all the neighbouring tribes on both sides of the lake. On account of its beautiful situation and healthy and pleasant climate, Kawele has been called 'the watering-place of explorers.' Pop. 3000.

Ukase' (Russ. *ukasat*, 'to speak'), in Russian, the name of edicts issued either by the Czar or the Senate, respecting legislative or administrative measures. They have the force of laws until superseded by subsequent orders, promulgated in the same manner. In 1827, the ukases, which had accumulated since 1649, the date of the last attempt at codification, were collected, by order of the Czar Nicholas, in 48 vols. Since then they have been collected annually, and form the basis of the *Swod* or Imperial Code.

U'kert, Friedrich August, a German historian, born at Eutin, October 28, 1780, studied at Halle and Jena, and was successively inspector at the Gotha gymnasium and librarian at the ducal library. He died May 18, 1851. His chief writings are *Geographie der Griechen und Romer* (3 vols. Weim. 1818-46), and *Ueber Dämonen, Heroen und Genien* (Leip 1850). In conjunction with Heeren, U. wrote a *Geschichte der Europäischen Staaten*; and with Jacob, *Merkwurdigkeiten der herzoglichen Bibliothek zu Gotha* (3 vols. Leip. 1835-38).

Ukraine' (Slav. 'border-land'), the name originally of the Polish frontier towards the Tartars, and latterly of the fertile, ill-defined region in the basin of the Dnieper, which was long an object of bitter contention between Poland and Russia. The latter power acquired the portion lying on the E. side of the Dnieper by the peace of Andrussov (1667), and subsequently, on the second partition of Poland in 1793, the western portion also, which is mostly comprised in the government of Kiev (q. v.). The historical U., also called Little Russia, consists of the governments of Kiev, Kharkov, Tchernigov, and Poltava.

Ulcera'tion is defined by Mr. Paget as 'that part or effect of an inflammatory process in which the materials of inflamed tissues liquefy or degenerate, are cast off in solution or very minute particles from free surfaces, or, more rarely, are absorbed from the substance of the body. When degenerate or dead substance is cast off in one or more portions visible to the naked eye, the process is usually called gangrene; when the portions are not so visible, or are quite dissolved, it is called U.' The matter discharged during the process of U. may be sanious or foul, ichorous, contagious, &c., and as the healing process advances, the matter gradually approaches to healthy pus.

Ul'cers (Lat. *ulcus*, 'a wound') are the granulating surfaces resulting from the process of ulceration which may have been going on around a wound, or after the separation of a slough. U. are divided into two classes, according to the constitutional causes on which they depend, and the local characters which they present.

1. *U. depending on Constitutional Causes.*—Of this class twelve varieties are described, of which the most important are—(1) The *simple* or *healthy* U., such as that which follows accidental injury in a healthy person. The base is level and slightly depressed, the edges shelve gently, and are scarcely harder than the adjacent healthy skin, the granulations are florid, uniform, small, and vascular, and the pus is healthy. The treatment

consists in protecting the ulcer from irritation or congestion, by dressing it with dry lint, or simple water dressing. (2) The *inflammatory* U., usually small and single, the surrounding skin being hot and red, and generally œdematous, the edges are abrupt, irregular, and shreddy; the base is level and but little depressed, and owing to the absence of granulations looks raw, the colour being ruddy, ash grey, or yellowish. Burning pain is generally felt in the part. The discharge is ichorous, then watery, frequently mixed with blood, excoriating the edges owing to its acrid nature. The treatment consists in subduing the inflammation by rest, and by warm soothing applications. In cases of *inflammatory* U., the patient, who is generally weak and debilitated, should have nourishing diet and general tonic treatment. (3) *Strumous* U. often follow softening of sub-cutaneous masses of tubercle. Their most common site is the lymphatic glands in the neck and groin, and on the face and head. The U. are originally small and oval, but they usually coalesce into irregular shapes; the base is soft and unequal; the granulations are large, pale, soft, and bleed easily; the edges are undermined, pale-pink or purplish; and the pus is thin, greenish yellow, and sometimes curdy. The treatment consists in the general treatment of Struma (q. v.), viz., generous diet, cod-liver oil, and tonics. (4) *Syphilitic* U. appear in connection with secondary or tertiary syphilis, most frequently the latter. There are two forms of tertiary U.,—the *superficial*, which follows ulcerative eruptions; and the *deep*, which usually commence in the softening of a subcutaneous gummatous swelling, leaving a circular, indurated, sloughing sore. This form may penetrate even to the periosteum or bone. The discharge from such U. is contagious. The first indication of treatment is to subdue the inflammation. The calomel vapour-baths may be applied to the whole body, or in the form of local fumigation, with a mercurial lotion or ointment to the part; and, for a permanent cure, a course of mercury, in some form or other, is necessary. The others are *eczematous* U. resembling the inflammatory, but complicated with eczema of the surrounding skin; *cold* U., also resembling the inflammatory, and occurring in persons of feeble circulation; *senile* U., having a tendency to slough; *scorbutic* U., which have on their surface the vibices and petechiæ of scurvy; *gouty* U., appearing over gouty deposits; *lupous* U., following the appearance of tubercles of Lupus (q. v.); *rodent* U., strumous affections occurring most commonly on the head and face; *cancerous* U., which may commence in the skin, or may occur from the adherence of the skin to a cancerous mass, the skin being infiltrated with Cancer (q. v.).

2. *U. depending on Local Conditions.*—The chief of these are —(1) *Varicose* U., caused by the pressure of the blood in varicose veins above, are usually situated above the inner ankle. The treatment consists in relieving the congestion by elevating the limb, subduing the inflammation by emollient applications, and the application of well-regulated pressure, which may be effected by the indiarubber bandage. (2) The *callous, chronic*, or *indolent* ulcer is usually situated on the leg, which it sometimes encircles. Any kind of ulcer may become chronic. The peculiarity consists in its chronicity, and its base is deep, flat, pale, or tawny; the edges are raised and callous; the granulations are very small, and the pus is thin and offensive. The most effectual mode of treatment is by applying a blister over the whole sore and its edges. In some cases strapping and bandaging are sufficient; but in other cases, incisions through the ulcer and into the healthy parts, on all sides, may be necessary. Transplantation and Grafting of Skin (q. v.) is often of great value in the treatment of U. Others are *œdematous* or *weak* U., such as occur in œdematous limbs; *exuberant* U., in which the granulations project considerably beyond the surface, and which may be treated by pressure and the application of nitrate of silver or sulphate of copper; *hæmorrhagic* U., depending upon a variety of causes; *neuralgic* U., attended with great pain; and *inflamed* U., depending for their condition on local irritation.

Uleaborg (Finn. *Oulu*), the largest and furthest N. government of the grand-duchy of Finland. Area, 59,261 sq. miles; pop. (1875) 193,494. U. is well watered by the Lakes Uleaträsk, Kitkajärvi, Kiando, Enare, and others, and by the rivers Oulunjoki, Kemijoki, Ulea, and Tornea, of which the latter, with its affluent the Muanio, forms the boundary with Sweden. In the interior and E. parts the chief features are woods and swamps; in the coast districts there is considerable cultivation. Fishing and wood-cutting are the chief occupations. In the N. are about 600 Lapps, who live by their reindeer.—**U.**, the capital, on the Gulf of Bothnia, and situated at the mouth of the Uleaelf, is the seat of the governor, has a lyceum, a hospital, a dock, and several factories, and carries on trade in tar, pitch, and wood. U. was founded in 1605, in great part burnt in 1822. In 1854 the English burnt several ships in the harbour. Pop. (1875) 8700.

Ule'ma (*i.e.*, 'learned') is the name given by the Turks to one who has passed through a complete course of liberal education. As this means solely the study of the Koran, and as the Koran is the source of all human as well as divine law, the U. are divided into *Imaums* (q. v.) or religious teachers, *Muftis* (q. v.) or expounders of the law, and *Cadis* (q. v.) or judges.

U'lex. See FURZE.

Ul'filas (the Greek form of the Gothic Ulfila, *i.e.*, *Wulfila*, 'a wolf') was born in 311 A.D., in one of the Gothic settlements to the N. of the Danube. He was probably of pure, perhaps noble Gothic blood, the story told by Philostorgius, that his progenitors were among the prisoners brought by the Goths from Cappadocia in 258, resting on very insufficient authority. Being sent to Constantinople on an embassy—possibly as a hostage—he adopted the Christianity of the capital, which was then of the Arian type, and was appointed 'Anagnostes;' and it was probably while holding this office, which in the Greek Church involves preaching as well as reading, that he executed the Gothic translation of the Scriptures. Early in the year 341, having just reached the required age, he was consecrated bishop of the Goths by Eusebius of Nicomedia at Antioch, and immediately returned to his people across the Danube. After labouring among them for seven years, he and his converts were obliged by the persecution of the heathen prince Athanaric to take refuge within the limits of the Roman empire, and for the rest of his life he continued to labour in the country of the Balkans. Subsequently to the first Gothic immigration and shortly before the battle of Adrianople in 378 U. seems to have been employed in fruitless negotiations between the Gothic and Imperial generals; and three years after (in 381) he died at Constantinople, having come there partly to remonstrate with a lapsed sect of semi-Arians, partly to petition the emperor for a General Council. U. translated into Gothic both the Old and the New Testaments, with the exception apparently of four books (1 and 2 Samuel, and 1 and 2 Kings); but only a small proportion of his work has been preserved. Mark is the only one of the Gospels that is complete; the Acts of the Apostles, the Epistle to the Hebrews, those of James, Peter, John, and Jude, and the Apocalypse, are altogether lost; and the Old Testament has left only a few fragments. But the fact that they furnish the oldest text of any German tongue, renders even the minor relics of inestimable value to the philologist. The principal MS. is the *Codex Argenteus*, written with silver letters on a purple parchment, which was discovered by Arnold Mercator about the end of the 16th c. in the Abbey of Werden near Düsseldorf, and after various vicissitudes was enshrined in silver at Upsala in Sweden. Portions of the Epistle to the Romans were found on a palimpsest (*Codex Carolinus*) at Wolfenbüttel in 1756, and portions of other Pauline epistles on palimpsests at Bobbio by Mai and Castiglione in 1818. A Gothic paraphrase, probably of the 6th c., based on U.'s version of John's Gospel, was published by Massmann (Munich 1834). The chief editions of U. are Francis Junius (Dort. 1665, Amst. 1684), Edward Lye (Oxf. 1750), Lahn (Weissenfels 1805), Gabelentz and Löbe (Leip. 1843-60), Massmann (Stuttg. 1857), and Stamm (Paderborn 1858, &c., new ed. by Heyne, 1874). The original authorities for the life of U. are (1) Philostorgius as quoted by Photius; (2) incidental allusions in the ecclesiastical historians Socrates, Sozomen, Theodoret, and the author of the Acts of Nicetas on the one hand, and the secular historians Drosius, Jordanes, and Isidore on the other; (3), contemporary notices quoted on the margin of the MS. containing various ecclesiastical writings by an Arian bishop, Maximinus. See also Ihren, *Analecta Ulphiliana* (Upsala 1769); Waitz, *Ueber das Leben des U.* (Hann. 1840); Bessel, *Ueber das Leben des U.* (Gött. 1860); Uppström, *Codices Gotici Ambrosiani* (Leip. 1868); and Bernhardt, *Vulfila, oder die Gothische Bibel* (Halle 1875).

Uliasutai, the capital of the Chinese province of Shen-si, in Mongolia, on the line between Si-Ngan-Foo and the Russian

frontier. It is an important depôt for the central Asiatic trade with China, and is defended by a garrison of Chinese. The pop., partly Chinese, partly Mongolian, is greatly increased during the fair by the Mongolian nomads, who pitch their tents in the vicinity. Owing to the occasional eruption of the Dzungar rebels from Urumsti, the Russians have failed to open a trade at U., though they tried repeatedly since 1868.

Ull'mann, Karl, a Protestant theologian, born March 15, 1796, at Epfenbach in the Palatinate, studied theology at Heidelberg and Tübingen, and became extraordinary professor (1821) of theology at Heidelberg, and ordinary professor at Halle (1829) and at Heidelberg (1836). In 1828 U. started with Umbreit (q. v.) the *Theologische Studien und Kritiken*. In 1853 he was made a member of the 'Oberkirchenrath' of Baden, of which he became 'Direktor' in 1856 at Karlsruhe, where he died, January 12, 1865. U.'s chief works are *Gregorius von Nazianz, der Theolog* (Darmst. 1825; 2d ed. Gotha 1867); *Johann Wessel, Ein Vorganger Luther's* [Hamb. 1834, afterwards as *Reformatoren vor der Reformation* (*ib.* 1841-42; 2d ed. 2 vols. 1866); *Historisch oder mythisch?* (Hamb. 1838); *Ueber die Sündlosigkeit Jesu* (*ib.* 1841; 2d ed. 1863); *Das Wesen des Christenthums* (Hamb. 1849; 5th ed. Gotha 1865). See Beyschlag, *Dr. Karl U.* (Gotha 1867).

Ulls'water (named after Ulla, a Norse chief), the second largest of the English lakes, lies between Cumberland and Westmoreland, and is 9 miles long by ¾ths of a mile wide, 210 feet deep, and 380 feet above the sea. Divided into three reaches, it grows by degrees more wild and beautiful as one goes up by steamer from Pooley Bridge at the foot to Patterdale at its head, where offshoots of Helvellyn tower upon the right hand, and on the left Birk and Place Fells.

Ulm ('the place of the *elm*'), a town of Würtemberg, capital of the Donaukreis, and one of the most important fortresses of Germany, lies on the left bank of the Danube, a little below its junction with the Iller, 53 miles W. of Augsburg by rail. Three bridges unite it with Neu-Ulm, a suburb on the right (Bavarian) bank, which is also included in the general lines of fortification. The Minster, in the centre of the city, is the largest Protestant church in Germany. It is in pure Gothic style, and was commenced in 1377, but is still unfinished; the tower when completed will be 514 feet in height. The interior originally consisted of a nave and two aisles, but in 1507 the latter were divided, the total breadth being 167 feet, and length 477. The choir stalls by the elder Sylin (1469-74), the holy-water basin by the younger Sylin (1507), the pulpit, ciborium, &c., are well worthy of note; the organ (built in 1856) is the largest in Germany, containing 100 stops and 6286 pipes. The Rathhaus (16th c. Transition style), with remains of frescoes; the Fischkorsten, a beautiful fountain erected in 1482 by the elder Sylin; the Neue Bau, containing the Government offices, the gymnasium, the industrial school, and the hospital, are among the most important of the other buildings. The chief industries are linen-weaving, cutlery, and clock-making. U. is also celebrated throughout Germany for its confectionery, and is a centre for considerable trade in wood and garden produce. Pop. (1875) 30,222. U. first appears in history in the time of Karl the Great, by whom it was made a villa-regia. In 1134 it obtained the privileges of an imperial city, and gradually increased in importance till at the period of the Reformation it was the chief member of the Swabian Confederation. It adopted Reformed principles, but had in 1546 to yield to Karl V., and shared in all the horrors of the Thirty Years' War. In 1620 a truce between the Evangelical and Catholic parties was signed here, and on March 14, 1647, the armistice between the French, Swedes, and Bavarians. In 1803 U. ceased to be a free city, and became the capital of the Ober-Donaukreis; and two years after the Austrian General Mack, having been defeated in the immediate neighbourhood by Napoleon, shut himself into U., but had to surrender with 23,000 men. Since 1809 U. has belonged to Würtemberg. See Pressel, *U. und sein Münster* (Ulm 1878); Hassler, *Ulms Kunstgeschichte im Mittelalter* (Stuttg. 1872).

Ulma'ceæ, a natural order of apetalous dicotyledonous trees or shrubs, possessing bitter, mucilaginous, astringent properties. Dr. Hooker places the genera at 3 or 4, and the species at about 18, distributed through the N. temperate zone. *Ulmus* is the principal genus. See ELM.

Ul'na, one of the two bones of the fore-arm of Vertebrata—the companion bone to the radius (see ARM). In birds it is longer than the radius; but in ruminants, in bats, and in such Ungulates as the horse, the U. dwindles to a mere appendage of the radius.

Ulodon'dron, an extinct genus of plants found in the Carboniferous or coal formations. The stem was marked by small scars of somewhat rhomboidal form, and which represented the attachments of leaves or fronds. A double series of larger markings is arranged on opposite sides of the stem, these being absent in Lepidodendron (q. v.). By most palæontologists, U. is regarded as a near ally of Lepidodendron.

Ulpia'nus, Domit'ius, an eminent Roman jurist of Tyrian origin, flourished in the 3d c. A.D. He was held in high honour at court, especially during the last years of his life, and filled the offices of Scriniorum Magister, Præfectus Annonæ, and Præfectus Prætorio. He was assassinated by soldiers in the year 228. The *Digest of the Civil Law* contains 2462 excerpts from his writings, which thus form about one-third of the whole collection. His style, though somewhat diffuse, is clear and direct. He was a man of great acumen and sound common-sense. The vast influence of the Roman civil law on the modern world is in a great measure due to his influence. See *Domitii Ulpiani Fragmenta* (best editions, Hugo, Berl. 1834; and Bocking, Bonn 1836). Also Schelling's *Dissertatio critica de Ulpiani Fragmentis* (Bresl. 1824), and Heimbach, *Ueber Ulpians Fragmente* (Leip. 1834).

Ulri'ci, Hermann, a German philosopher and critic, was born at Pforten in Niederlausitz, 23d March 1806, studied law at Halle and Berlin, and was appointed professor of philosophy at Halle in 1834. He is best known as a Shakespearian critic. His works show great learning and a remarkable power of theoretical criticism, but are marred by the 'occasional alliance of excessive profundity of interpretation with heaviness of style.' The chief are *Geschichte der hellenischen Dichtkunst* (2 vols. Berl. 1835), *Shakespeare's Dramatische Kunst* (3 vols. Halle 1839; 3d ed. Leip. 1868, trans. by L. Schmitz, 2 vols. Lond. 1846), *Das Grundprincip der Philosophie* (2 vols. Halle 1845-46), *Gott und die Natur* (Leip. 1862, 3d ed. 1875), *Leib und Seele* (2 vols. Leip. 1866, 2d ed. 1874), *Abhandlungen zur Kunstgeschichte als angewandter Æsthetik* (Leip. 1876).

Ul'ster (Danish form of the Irish *Uladh*, or *Dal-Araidhe*), the most northerly province of Ireland, embraces the nine counties of Antrim, Armagh, Cavan, Donegal, Down, Fermanagh, Londonderry, Monaghan, and Tyrone. Area, 8315 sq. miles, or 5,321.580 acres; pop. (1851) 2,011,991, (1871), 1,833,228, of whom 894,525 were Catholics, 484,425 Presbyterians, and 398,705 Protestant Episcopalians. Emigration, the chief cause of the decrease in population, is still continuing, 16,723 persons having left the province in 1877. In that year the valuation amounted to £4,226,000, the poor-rates to £152,420, and the number of paupers to 57,015; in 1878 there were 1,295,872 acres under tillage, 2,634,065 in grass, meadow, and clover, 62,684 of woods and plantations, 5959 fallow, and 1,322,820 bog and waste. Owing to the 'Plantation of U.' in 1610 (see IRELAND) the Celtic element is weaker here than in the other provinces, and it is very unequally distributed, since, while populous Antrim contained (1871) but 15 persons who could speak only Erse, and 2232 speaking both Erse and English, Donegal had 18,629 of the former, and of the latter 44,506. From James' colonisation dates the prosperity of U., whose principal source is the cultivation and manufacture of flax.

Ul'ster King-of-Arms, the chief heraldic officer for Ireland, whose office was created by Edward VI. in 1552. Under the 'King' are two heralds, four pursuivants, a registrar, and a clerk of records.

Ultima'tum (Low Lat. 'last,' 'extreme'), in diplomatic negotiations is the final deliverance of the one party, the rejection of which usually involves an immediate rupture of diplomatic relations and a declaration of war.

Ul'timus Hæ'res ('the last heir') in Scotch law is the Crown.

Ultramarine', a brilliant blue colour, in very extensive use by painters, paper-stainers, calico-printers, and others. The substance previous to the year 1828 was obtained only from lazulite or lapis lazuli, a beautiful and costly mineral sub-

stance. The mineral being rare, and much prized for ornamental inlaying, and the colour being of unapproachable brilliance and depth, it was an extremely expensive pigment. In consequence, strenuous efforts were made to obtain an equally valuable product by artificial means. In 1824 the French *Société d'Encouragement pour l'Industrie Nationale* offered a premium of 6000 francs for the manufacture of an U. blue, possessing all the qualities of that extracted from lapis lazuli, and in 1828 the prize was awarded to M. Guimet of Lyon, who after four years' investigation succeeded perfectly in producing the valuable substance by a synthetical process. The U. thus made was declared by competent judges to be in every way equal to the natural product; and Horace Vernet, who was one of the first to use the material, after employing it in his famous picture, 'The Battle of Fontenoy,' declared the substance to be even superior to natural U. M. Guimet's factory has continued since that time to manufacture U. of the highest quality. His process was never made public; but in the same year, 1828, Gmelin, a German chemist, made public a process for manufacturing U. which was extensively taken up and worked in Germany. These two discoverers may thus be fairly credited with the joint honours of this most brilliant triumph of chemical research. The composition of artificial U. varies considerably, as does also its colour, the latter showing many tones of blue and violet, and there is further a green U. which is obtained in an intermediate stage of the manufacture. It is prepared by first dissolving silica in caustic soda, to which hydrate of alumina is then added in the proportion of 30 of alumina to 35 of silica. The mixture is dried and mixed with an equal weight of sublimed sulphur, and to this again is added a mixture of equal parts of sulphur and sodic carbonate, weighing as much as the silica and alumina mixture. The whole is then submitted for two hours to a red heat in closed crucibles, whereby green U. is produced, and this is again heated in crucibles till the desired blue hue is developed. U. is manufactured extensively in Germany, France, and Belgium; but of the total made in 1872, upwards of 8300 tons, nearly one-half was produced in Germany. See Vogelfang, *Naturliche Ultramarin-Verbindungen* (Bonn 1873).

Ultramon'tane (Lat. *ultra*, 'beyond,' and *montes*, 'mountains,' *i.e.*, the Alps) has changed its meaning since Bacon wrote in his *Observations on a Libel*:—'He is not papable, because he is an *ultramontane*, of which sort there hath been none these fifty years.' Then U. was used by Romans in reference to adherents of the Gallican Church (q. v.); now it is used by Europe in reference to Rome itself, and an Ultramontanist is one who implicitly accepts the dogma of papal infallibility. See ROMAN CATHOLIC CHURCH.

Ulwar'. See ALWUR.

Ul'verston, a town of Lancashire, England, on Morecambe Bay, 22 miles N.W. of Lancaster by rail. It has cotton, woollen, linen, and paper mills, and manufactures of gunpowder, besides a considerable export trade in the iron, copper, slate, and agricultural produce of the district. Pop. (1871) 7607.

Ulyss'es, Ulyx'es, or **Ulixes** (Latin forms of the Greek **Odyss'eus**), one of the heroes of the Trojan War, celebrated in song and story both by Greek and Latin writers, was, according to the Homeric account, king of the small Ionian isle of Ithaca. He was induced, though unwilling, to become one of the chiefs in the expedition against Troy, and greatly distinguished himself during the siege. When the city fell, U. and the band under his charge set out on their return home. Their adventures are narrated in the second great Homeric epic, the *Odyssey*. Shortly after their departure, they were driven on to the coast of Thrace by a storm. Then a N. wind blew them down the Ægean and across the Levant, till they came to the country of the Lotophagi, who subsisted on the lotus plant, the eating of which caused men to forget their homes and remain at rest. With difficulty U. rescued his companions from the lotus-lethargy, and sailed away to the island of the Cyclopes, a race of one-eyed monsters. Polyphemus, one of these, enclosed the adventurers in his cave, and ate several of them. U. made the giant drunk, burnt out his single eye, and got off by an ingenious stratagem. But his crew only escaped one danger to fall into another. At the island of Ææa, tenanted by the sorceress Circe, they were changed into swine. With the help of the god Hermes, U. re-transformed them, and the whole party were then amicably feasted by Circe, who directed the leader to descend to Hades and inquire of Tiresias, seer and poet, how he might get back to his home. After reaching the sunless land of the Cimmerians beyond the ocean-stream, U. made the descent and received prophetic encouragement. A second visit to Circe followed, and U. was warned of the perils in store for him and told how to escape them. Bound to the mast, whilst his companions with deafened ears rowed with all their might, U. heard undeluded the song of the Sirens (q. v.), and afterwards passed unharmed between Scylla and Charybdis. At the island of Thrinakia ('the trident-isle,' *i.e.*, Sicily) the sailors killed and eat the finest of the sacred oxen of Helios. As a punishment, they were all destroyed in a storm, with the exception of U., who, carried over the deep for ten days on some wreckage, was at last thrown on the isle of Ogygia, where he was hospitably received and entertained for eight years by the nymph Calypso. At last, on a raft, he continued his voyage, but was again wrecked and thrown on the island of Scheria (later Kerkyra, mod. Corfu), the king of which, having learned who he was, sent him home to Ithaca, which he reached after a twenty years' absence. During this time his wife Penelope had been courted by a number of island princes, who had made themselves free with the stores of the absent monarch. She had, however, remained true to him, and U., on his appearance, soon made short work of the insolent suitors, and resumed the rule of the island. The story of the hero has been made the subject of many disquisitions and moral interpretations; and it has been treated over and over again in all modern literatures. One later legend represents U. as again sailing to still remoter regions, inspired by an insatiable thirst for travel. This form of the story is treated in Tennyson's poem of U., which is an exquisite character-study of the old hero from a modern standpoint. The character, as represented in the old Greek tales, is by no means a perfect one. U. is brave, clever, and persevering; but he is cunning, deceitful, and treacherous. He is often represented as the Greek ideal of a man; and no doubt he may be taken as a popular ideal; but he is far below the ideal man of the higher Greek literature,—as we find him, for instance, represented in Plato. Of late, the romantic story of U. has been transformed into a solar myth. The hero's changeful adventures are 'the lights and shadows of a stormy and gloomy day;' his strong desire to see his wife and home again, which no allurement can permanently destroy, is, it seems, a symbol of Helios, 'who cannot turn aside from the course marked out for him, whether in his daily or his yearly round,' &c.

Uman', a town in Russia, government of Kiev, on the Umanka, an affluent of the Bug, 110 miles S.S.E. of Kiev. It has five churches and a synagogue, and has an active trade in farm produce. Pop. (1870) 15,393.

Umarkote'. See OMERKOTE.

Umball'ah (*Ambála*), the chief town of the district and division of the same name, in the Punjaub, British India, 120 miles N.N.W. of Delhi. Pop. (1868) 24,037, besides (1876) 26,659 in the cantonments, which lie a few miles to the S.E. It is a walled town with brick houses. The imports (excluding those by rail) are valued at £150,000; the exports at £70,000. U. is an important military station for all arms, and the railway station for Simla. It was the scene of the great *durbar* of 1869, when Lord Mayo in much state received Shere Ali, the late Ameer of Afghanistan. The *district* of U., which lies at the foot of the Himalayas between the Sutlej and Jumna rivers, has an area of 2621 sq. miles. Pop. (1868) 1,035,488. It is also watered by the W. Jumna Canal. The crops are wheat, millets, rice, gram, Indian corn, and barley.

Umbellif'eræ, an important order of calycifloral dicotyledons, containing about 150 genera and upwards of 1300 species, varying in size from very small plants to the most gigantic of the herbaceous category. The stems are round or furrowed, usually hollow, and solid at the nodes; the leaves alternate or compound, rarely simple. There is an inflorescence of usually regular and compound umbels, with an involucre of whorled bracts at the base of the primary rays, and of bracteoles at the secondary. The flowers are small, the calyx superior, limb none or five-toothed, the petals and stamens five, filaments incurved, and anthers versatile. The ovary is two-celled. The fruit consists of two indehiscent compressed carpels, each carpel

normally five- or ten-ridged, attached to and often pendulous from an entire or split slender axis (*carpophore*), the pericarp often traversed by oil-canals (*vittæ*). U. is one of the most natural and consequently one of the most easily recognised of the orders of plants, at the same time it is one of the most difficult for the systematic botanist to divide satisfactorily. It is prominently represented in N. Europe, N. and W. Asia, and N. Africa, being rarer in America, S. Africa, Australia, and tropical mountains. The properties are various. Thus we have (1) species with poisonous, acrid, watery sap in *Conium* (see HEMLOCK), *Cicuta* (see WATER HEMLOCK), *Œnanthe* (see WATER DROPWORT), *Æthusa* (see FOOL'S PARSLEY); (2) esculent species in Angelica, Celery (q. v.), Fennel (q. v.), Parsley (q. v.), Carrot (q. v.), Parsnip (q. v.), Samphire (q. v.), Skirrit (q. v), &c. (3) Such as yield gum-resin as Assafœteda (q. v.), Galbanum (q. v.), Opoponax (q. v.), Ammoniacum (q. v.). (4) Those containing an essential oil in their fruit, as Anise (q. v.), Dill (q. v.), Coriander (q. v.), Carraway and Cummin (q. v.).

Um'ber (Lat. *umbra*, 'a shade'), a pigment having various shades of brown and buff, consisting of a natural ochreous earth with some proportion of peroxide of manganese. The commercial varieties are known as Turkey U, raw and burnt, and English U., the latter being an artificial ochrey admixture.

Um'ber (*Scops umbretta*), a species of *Grallatorial* birds included in the heron family (*Ardeidæ*), having a compressed bill, and the tip of the upper mandible hooked. The furrow of the bill, in which are the nostrils, extends nearly the whole length of the bill. The average size of the U. is that of the common fowl. The name is derived from the colour of the plumage. The males are crested.

Umbey'la (*Ambeyla*), a mountain-pass on the N W. frontier of British India, leading N. from the district of Peshawar. The total length from the plain to the village of U., just beyond the crest, is about 11½ miles. The pass only permits an advance in Indian file, and is everywhere commanded by mountains 4000 feet high. It is celebrated as the scene of the U. campaign of 1863. Continual raids had rendered it again necessary to attack the fanatical colony of Mahommedans—Pathans and Hindustanees—who had in 1858 been expelled from Sitana. It was expected to be a mere expedition of three weeks, but Sir Neville Chamberlain, at the head of 9000 men, was practically blockaded in the U. pass from October 18 to December 16. The British casualties were 847 killed and wounded, while the enemy are said to have lost 3000. At last they broke up, owing to internal dissensions, and the rebel settlement at Mulkah, the object of the expedition, was burned. See *The Indian Mussulmans*, by W. W. Hunter (Lond. 1872).

Umbil'ical Cord, or **Na'vel String**, the structure passing from the *umbilicus* or *navel* of the *fœtus* or embryo of higher mammalia to the *placenta* or 'afterbirth,' and by means of the blood-vessels of which blood is conveyed to and from the maternal structures. The U. C. is developed about the end of the fifth month of pregnancy. It is composed of two *umbilical arteries* and a single umbilical vein united by a gelatinous tissue, the *gelatin of Wharton*. The average length of this cord is about 20 inches. The blood which is destined to nourish the *fœtus* passes from the placenta of the mother along the *umbilical vein*, which enters the abdomen of the fœtus at the umbilicus, whilst the umbilical arteries return the fœtal blood to the *Placenta* (q. v.). At birth the umbilical cord is severed, the bulk of the cord being cast off with the placenta.

U. C., in botany, is a name formerly used for the stalk by which the ovule or seed of a plant is attached to the Placenta (q. v.). It is now generally termed the funicle or funiculus (*funis*, 'a cord'). See OVULE and SEED.

Umbil'ical Her'nia occurs frequently as a congenital affection, the bowel protruding through the unclosed navel. The bowel should be kept reduced by a pad, which should cover the whole ring, and by careful attention for a few months a cure may be effected. In the adult, U. H. is frequently a result of obesity or of pregnancy. The hernia is covered only by the skin and expanded linea alba, and is generally reducible. When irreducible, the strangulation is more frequently due to the entanglement of distended bowel in the folds of omentum than to the presence of a constricting band; so that, when an operation is necessary, the bowel and omentum should be unravelled, and the finger passed beneath the ring to feel for the point of stricture. See HERNIA.

Um'bonate, a term in botany, meaning 'round,' with a projecting point in the centre, like the boss or *umbo* of an ancient shield; as the pileus of many species of *Agaricus*.

Um'breit, Friedrich Wilhelm Karl, a German theologian, born at Sonneborn, near Gotha, April 11, 1795, studied at Göttingen, and in 1820 was appointed professor of philosophy at Heidelberg, where with Ullman he founded (1828) the *Theologische Kritiken und Studien*, and in 1829 was transferred to the theological faculty. He died April 26, 1860. The chief works of U. are *Coheleth Scepticus de summo bono* (Gött. 1819), *Lied der Liebe* (2d ed. Heidelb. 1828), *Uebersetzung und Auslegung des Buches Hiob* (2d ed. Heidelb. 1832), *Kommentar über die Sprüche Salomo's* (ib. 1826), *Uebersetzung und Erklärung auserlesener Psalmen* (2d ed. Hamb. 1848), *De Veteris Testamenti Prophetis* (Heidelb. 1834), *Grundtöne des Alten Testaments* (ib. 1843), *Kommentar über die Propheten* (4 vols. 1841-46), *Neue Poesie aus dem Alten Testament* (1847), *Die Sünde* (1853), *Der Brief an die Römer* (1856).

Umbrell'a (Ital. *ombrello*, from Lat. *umbra*, 'a shade'), a familiar covered sliding frame, carried as a protection from the sun or rain. It had its origin in the East in very remote times, where it was regarded as an emblem of royalty or a mark of distinction. In Assyria the king alone used it; while in Egypt and India the privilege of carrying it extended to persons of quality. The title *Ch'hatra-pati*, or 'Lord of the U.,' was formerly much coveted by Mahratta princes; and the King of Burmah is pleased to style himself 'King of the White Elephant and Lord of the Twenty-four Umbrellas.' An U. of imposing dimensions is held as a mark of regal dignity in countries of Western Africa. The finials of Buddhist topes take their form from the U.; and a cardinal's hat is believed to be a modification of the U. suspended in Basilican churches at Rome. The Harleian MSS. show that the Old English of high degree used sunshades; but as a defence from rain the U. seems to have been first used in England early in the 18th c., and then only by ladies, as an idea of effeminacy was associated with it. The first man who (about 1750) had the hardihood to carry one habitually in London was Jonas Hanway, founder of the Magdalen Hospital. Oiled silk for covers, cane for 'stretchers,' and whalebone for 'ribs,' were the materials used in early umbrellas. Oiled silk was supplanted by gingham, and it in turn gave way to alpaca, silk, and mixed fabrics. Light frames of metal were introduced by Holland in 1840, and the trough-shaped 'paragon' ribs and stretchers by Fox in 1851. Metal furniture is principally made at Birmingham and Sheffield, while London and Manchester are the greatest seats of the making-up industry. The exports of umbrellas and parasols from the United Kingdom in 1877 amounted in value to £351,816.

Umbrell'a Bird (*Cephalopterus ornatus*), a species of *Conirostral* birds, allied to the Fruit Crows, and so named from the peculiar form of the crest borne on the head. This crest is composed of long and slender feathers, which slope backwards when at rest. In the erect position the shafts of the feathers radiate like the ribs of an umbrella, completely covering the head, and forming a dome of a beautiful blue colour. The breast bears a prominent 'tuft' of feathers, which appear to spring from a fleshy growth. The U. B. is a native of S. America, and has a local distribution. It attains the size of a crow, and its general colour is a rich glossy black.

Um'bria, one of the ancient divisions of Central Italy, lying between the Tiber and the Adriatic, varied somewhat in its boundaries at different periods, but as the sixth region of Augustus it was bounded S. by the Nar, the Central Apennines, and the Æsis, and N. by the Rubicon and an irregular mountain line extending to the sources of the Tiber. Beyond the Æsis lay Picenum, beyond the Rubicon, Gallia Cisalpina. Though deserving Martial's epithet 'montana,' U. contained several rich plains and not a few important towns, the ruins of one of which, Iguvium, has yielded remains of priceless value to ethnology. See EUGUBINE TABLES. The Via Flaminia ran through it from the valley of the Clitumnus at Forum Flaminii northwards to the Adriatic at Fanum Fortunæ, and formed

a most important military line. Of the products of U., vines, olives, and orchard trees are mentioned; but it was better known for its sheep, and especially its cattle. Of history apart from that of imperial Rome it has almost none; after its defeat in alliance with Etruria in B.C. 308, and another some twelve years later in the third Samnite war, it vanishes almost entirely from the pages of the Roman annalists, and the enfranchisement of B.C. 90 was earned rather than extorted. In pre-historic times, however, the Umbrians appear to have been the ruling people of Italy, and to have yielded the supremacy to the Etruscans even before the Romans seized it. Recent philological researches have made it probable that with the Oscans and Latins they formed a special branch of the Aryan family, distinct from both Teutonic and Celtic, though perhaps more closely allied to the latter than even to the Greek. See *Die Umbrischen Sprachen Denkmäler* (Berl. 1849), by Aufrecht and Kirchhoff, and *Umbrische Studien* (Berl. 1873), by Savelsberg.

Um'pire is properly the name given to a *third* arbitrator, called in to decide a question when the *two* previously appointed have failed to agree. The derivation of the word is uncertain.

U'mrer, a town in the district of Nagpur, Central Provinces, British India, 28 miles S.E. of Nagpur. Pop. (1872) 11,394. It has a considerable trade, being chiefly noted for its cotton goods with embroidered silk borders. There are 1150 looms, employing twice that number of journeymen, who receive from £1 to £2, 10s. per month.

Umritsur'. See AMRITSAR.

Unattached' or Non-Colle'giate Stu'dents, in the Universities of Oxford and Cambridge, are students who, under respective statutes of 1868 and 1869, are admitted members of the University without being attached to any college, hall, or hostel. At Oxford they are under the supervision of two 'Censors,' at Cambridge of the vice-chancellor and proctors; and at the latter University the Company of Clothmakers awards them three yearly scholarships of £50, tenable for three years. In 1878 the unattached students at Oxford numbered 256, at Cambridge 116.

Unau (*Cholœpus*), a well-known species of sloths or *Bradypodidæ*. Its fore feet are two-toed, and it has twenty-three pairs of ribs, this being the largest number found in the class *Mammalia*.

Unca'ria, a genus of climbing plants with hooked spines, belonging to the cinchona section of the natural order *Rubiaceæ*, natives of the E. Indies and tropical America. *U. gambir* is the most important, as yielding the gambier or *Terra Japonica* of commerce, a powerful astringent obtained by boiling the leaves of the plant and then evaporating the decoction until a thick residue results, which is moulded and dried in the sun. Gambir is used by the Malays in combination with areca-nut and betel-leaf as a masticatory. It is also shipped to China for tanning, and to Europe (principally from Singapore) for a similar purpose, serving as a substitute for catechu. Some botanists having united U. with the genus *Nauclia*, the name thus dropped was transferred by Burchall to the Grapple-Plant (q. v.) or *Harpagophytum*.

Un'cial Lett'ers (a name derived from a passage in Jerome in which he speaks of *literis uncialibus*, 'an inch long,' which, however, was probably written *initialibus*) is the name given to the characters, now regarded as capitals, in which the oldest Greek MSS. are written. The use of U. L., which are distinguished from the *cursive* or running hand by being formed separately, having no connection with each other, and in the earlier specimens without any spaces between the words, and with few marks of punctuation, prevailed from the 4th c. to the 10th c. (in liturgical books the 11th c.), when it was superseded by the *cursive*. The oldest form is square and upright; the later, narrow or leaning. See Scrivener's *Introd. to the Crit. of the New Test.* (Lond. 1861).

Unclean'ness. See PURIFICATION.

Unconform'able Stra'ta are such as do not lie regularly bedded in parallel planes, but the upper beds rest upon the upturned edges of the lower ones. This phenomenon is an evidence, doubtless, of the lapse of a long period of time between the deposition of the two sets of strata, during which period the first beds were consolidated, upheaved, and tilted from their horizontal position before the other series was laid down over them.

Un'ction (Lat. 'anointing with oil') is a practice perhaps reaching back to the rudest form of nature-worship. In the worship of the reproductive principle of nature, stone or wooden pillars (see ASHERA) were set up as rude forms of the Phallic symbol, and in further symbolism oil was poured on the top (*cf.* Gen. xxviii. 18). To this day in certain parts of India every village has its sacred stone, on which newly-married and barren women come and seat themselves after pouring oil on its top. But after the first rude meaning was lost, a sacredness continued to be attached to U. Thus among the Jews there was a holy anointing oil prepared with perfumes (Exod. xxx. 22-33), with which the priests, and the tabernacle, and all its furniture were anointed. Kings, too, were installed in their office by U., often seated on a sacred stone. It was considered to be efficacious even in healing the sick, and seems to have been used for this purpose in the early Church (*cf.* James v. 14). It soon came to be employed not only in this way (see EXTREME U.), and at the consecration of priests, but in all the principal sacraments.

Un'derclay, the bed of fire-clay which is almost invariably found beneath a seam of coal, and contains usually the peculiar fossil plant known as *Stigmaria*. It is now looked upon as the old soil in which the plants that formed the coal originally grew.

Un'derwriters, the name given to members of marine insurance companies, who being unable legally to take joint-stock because of the monopoly granted to the two chartered companies (the Royal Exchange and London), subscribed or *wrote under* their policies of insurance with the sums for which they severally bound themselves. The traditional system of underwriting still prevails, though co-ordinately with the privilege of companies which make it their business to grant marine insurance. See INSURANCE (Marine) and LLOYD'S.

Undines' (Lat. *unda*, 'a wave') were, according to the philosophy of Paracelsus, the spirits who inhabited the water. If a female spirit of this race married a man, and had a child, she received a soul. The history of the cares and sorrows of one of these imaginary beings forms the subject of an exquisite romance by La Motte Fouqué (q. v.), entitled *Undine*.

Un'dulatory The'ory of Light is the theory which regards the propagation of light as wave motion in a medium filling space. The possibility of light being propagated in waves was first propounded by Hooke in 1664; and the theory was a few years later applied by the Dutch philosopher Huygens to the explanation of several phenomena, such as double refraction. Newton, from as he thought its inability to explain other and more complex phenomena, did not accept this theory, but instead regarded light as being composed of minute corpuscles radiating from the luminous source in straight lines and with a great but constant velocity. It does not appear, however, that Newton had formed a definite theory; he merely gave possible explanations of different phenomena, explanations based upon extremely ingenious hypotheses, each of which applied to a certain group of phenomena and no other. Such a collection of arbitrary assumptions could scarcely have been regarded as a scientific theory by their author; but that it should have long lived as *Newton's Theory* is not surprising when it is remembered what an authority Newton was and is on all physical questions. The earlier partisans of the undulatory theory were no better, as regards the assumptions they made and the explanations they gave, than were their opponents the supporters of the emission theory; and not till Young and Fresnel attacked the question did the undulatory theory acquire the simplicity and efficacy which are essential to all true scientific theories. Fresnel especially, by his wonderful mathematical analysis, has placed the theory upon a sure basis; and the theory further commends itself inasmuch as it has predicted phenomena which were not before suspected.

The general nature of wave-motion is explained under the article WAVE; here we purpose to consider the special peculiarities characterising the ethereal undulations which constitute light and other forms of radiant energy. We know nothing of

the luminiferous ether except that it is so highly elastic that at any given portion through which radiant energy is being transmitted, a great number of waves differing in all their elements may co-exist. By suitable means we may experimentally separate these different rays, as when we obtain a spectrum (see SPECTRUM ANALYSIS). The simple geometry of wave-motion involves of necessity the well-known laws of reflection and refraction; and the possibility of obtaining a spectrum proves that in an ordinary ray of sun-light waves of nearly all lengths and refrangibilities between certain limits exist. Those of longest wave-length and least refrangibility are the invisible heat-rays; when the wave-length becomes ·0000266 of an inch, the ray becomes visible and appears of a dark red. This is the lower limit of visibility, and from this to the extreme purple ray whose wave-length is ·0000167 of an inch there are rays of intermediate wave-lengths, each of which has its own refrangibility and characteristic colour sensation. Beyond this limit there are other rays, which, though too fine to be directly perceptible to our organs of vision, may be studied by their action upon certain sensitive substances, such as are employed in photography, or are included under the class of fluorescent substances. It is thus apparent that in general a light wave is intensely heterogeneous, and that we can so easily separate its various components is due to the minuteness of the corresponding vibrations. These vibrations, however, are not so minute that we can wholly neglect their mutual interference; and to this phenomenon, by means of which Helmholtz has so successfully explained the consonance of musical chords, we must look for the explanation of dispersion. In many of its phenomena light naturally bears a close analogy to sound, since both are propagated by wave-motion. There is a whole group of phenomena, however, included under the name Polarisation (q. v.), which are peculiar to light and the other forms of ethereal radiant energy. To explain these phenomena it is necessary to assume that the luminiferous medium vibrates in a direction at right angles to the direction in which the ray is propagated. The undulations of ordinary unpolarised light are then supposed to take place in all planes passing through the axis of the ray, so that in any finite time the eye receives as many vibrations in one plane as another. When, however, the ray is a plane polarised ray, the vibrations all take place in a definite plane, which, according to Stokes, is perpendicular to the so-called plane of polarisation. The whole theory of circular, elliptical, and rotatory polarisation, then becomes an application of the well-known kinematical principles which regulate the composition of simple harmonic motions. One of the most beautiful developments of the undulatory theory is Fresnel's theory of double refraction. Light radiating from a single luminous source in a medium which has the same elasticity in every direction will propagate itself in spherical waves. If, however, the elasticity of the medium is different for different directions, the wave surface will evidently not be a sphere, and light will be propagated with different velocities in different ways. The resultant of the elastic forces resisting any displacement at any point will not in general act in the direction of the displacement; but Fresnel showed that in accordance with the first principles of crystallisation there must be three directions in every elastic medium in which these forces do act in the direction of the displacement. Assuming these directions to be parallel throughout the crystalline medium, he called them the *axes of elasticity*, and was then led to the construction in the crystal of a geometrical surface, the length of each radius of which was proportional to the velocity of propagation of light in its direction. This surface is of the fourth order, and its semi-axes, which are coincident with the axes of elasticity, are proportional to the elasticities in their directions. Now, conceive an ellipsoid with the same semi-axes, and let it be cut in any diametrical plane. At the centre of this section let perpendiculars be raised whose lengths are equal to the greatest and least radii of the section, then Fresnel showed that the loci of the extremities of these perpendiculars determined the form of the wave diverging from any point within the crystal. There are two directions, namely, the normals to the circular sections of the ellipsoid, in which the two sheets of the wave surface meet, and therefore the two rays have the same velocity; and these directions are the true optic axes of the crystal. For uniaxal crystals two elasticities are equal, and the ellipsoid becomes a spheroid, so that Huygens' famous construction for the extraordinary ray is a particular case of Fresnel's general theorem; and when the three elasticities are equal in all directions, the ellipsoid becomes a sphere and the velocity is the same in all directions. For a clear exposition of the whole theory and for Sir W. R. Hamilton's later developments, the reader is referred to Lloyd's *Wave Theory of Light* (3d ed. 1873). See also DIFFRACTION, INTERFERENCE, POLARISATION, &c., for more detailed treatment of special parts of the subject.

Unferment'ed Bread. See AERATED BREAD and BREAD.

Unferment'ed Wine Agita'tion, a disturbance which originated in the dissenting communities in Scotland caused by some extreme abstainers, who insisted that communion wine must be administered free from alcohol. The agitation has not been received with much favour by the public, but it cannot be said to have wholly died away.

Unghvar', a town of Hungary, in a district of the same name, on the river Ungh, a sub-affluent of the Theiss, 195 miles E.N.E. of Pesth by rail. The seat of a Greek bishop, it has a beautiful church, and a castle of great antiquity. There is considerable trade in rye, oats, hemp, cattle, and wine. Pop. (1870) 11,017.

Un'guents. See OINTMENTS.

Unguicula'ta ('clawed'), a term formerly employed in zoology to designate those animals in which the nails were developed to form prominent *claws*. Under this name Linnæus included Edentates, Rodents, Felidæ, and other quadrupeds. Cuvier extended the term to those animals having well-developed 'nails,' such as man, quadrumana, &c.

Ungula'ta, a large and important order of *Mammalia* or quadrupeds, embodying the sub-orders Ruminantia, Pachydermata, and Solipeda of former systems of classification. They are popularly known as 'hoofed' quadrupeds, from the toes being encased in largely-developed nails, called 'hoofs.' Three new sub-orders have replaced the groups mentioned above. These are the *Artiodactyla*, *Perissodactyla*, and *Proboscidea*. Some authorities, however, regard the Proboscidea as a distinct order of Mammalia. The general characteristics of the *Ungulata*, as an order, are sufficiently clear and distinct. The limbs are always four in number, and the perfect and functional toes are never more than four to each limb. Clavicles are absent throughout the group, the limbs being used solely for locomotion.

U'nicorn. The belief in the existence of a wild animal in form similar to the horse, with a single formidable horn projecting straight and pointed from the middle of its forehead, is very old and widely diffused. Ctesias, Aelian, Aristotle, and Pliny describe such an animal, but confess they never saw it. Its reputed home was now India, now Africa; and in collections the great tooth of the Narwhal (q. v.) was shown as the horn of the U. But the last two thousand years furnish no trustworthy evidence of a U. having at any time been observed, and anatomists show that its existence is *a priori* most improbable. The belief is probably to be traced to rude drawings in profile of certain straight-horned antelopes. The 'U.' of the English Bible (Vulg. *unicornis*, LXX. *monokerōs*) is an unhappy rendering of the Heb. *Reēm*, which Gesenius, following Alb. Schultens, 'without hesitation identifies with the *buffalo*.' The Supporters (q. v.) of the present Shield Royal—a *lion or* for England and a *U. argent* for Scotland—were introduced by James I., who had previously, as King of Scotland, borne *two unicorns*.

U'niform ('one form'), in its military sense, a particular kind of dress indicative of regiment and rank, was first introduced 'in a regular manner' in the French army, but not till the time of Louis XV. (about 1668). A U. was shortly afterwards adopted in the British army, in which red is the prevailing colour, as blue is in that of France and Germany, and white in that of Austria. A similar regulation respecting 'the cloth' was only introduced into the British naval service in 1748.

Uniform'ity, Act of. See ACT OF UNIFORMITY.

Unigen'itus, Bull. See JANSENISM.

Union City, a town of Pennsylvania, U.S., 23 miles S.E. of Erie by rail, has 4 churches, 3 banks, and 3 newspapers.

It has 2 flour-mills, 2 carriage and several furniture and other wood works, and a large tannery. Pop. (1870) 3400.—U. is also a township of Ohio. Pop. (1870) 5399.

Union Coll'ege, an educational institution of Schenectady, New York, U.S., comprises one faculty with twelve teachers and two tutors. There are two courses of study, a classical and a scientific, the latter being well supplied with apparatus of practical study. In 1872 it was affiliated with the Albany Medical and Law Schools of Albany University, the joint corporation taking the name of Union University. New buildings are now in progress. Four thousand alumni have left this college. U. C. was incorporated in 1795 through the efforts of General Schuyler, but owes most to the Rev. Eliphalet Nott, president from 1804 till 1865.

Union'idæ. See FRESHWATER MUSSEL.

Union Jack', the national flag of Great Britain and Ireland, consisting of a blue ground on which are displayed the red cross of St. George and the white and red diagonal crosses of St. Andrew and St. Patrick, the latter two being placed contiguously. The old English flag, the banner of St. George, white with a red cross, was in 1606 incorporated with the banner of Scotland, blue with white diagonal cross, in allusion to the union of the two kingdoms. This was proclaimed the national flag of Great Britain, 28th July 1707, but on the union with Ireland, the cross of St. Patrick, white with a diagonal red cross, was introduced, having its four limbs edged on one side with white. The latter part of the name was originally that of the *jacque* or surcoat, charged with a red cross, anciently worn by English soldiers (see JACK). In addition to its general use as a national flag, it is employed in the naval service, being placed in the upper quarter (next the mast), of the red, blue, and white ensigns. Far from defensible as a heraldic device, the banner is endeared to the nation by a thousand associations of heroism and pathos, and is universally regarded as an emblem of liberty.

U'nions, a trade term applied to textile fabrics composed of more than one kind of fibre, but principally to such as are made up of varied combinations of cotton, flax, jute, and hemp.

U'nit. Every quantity consists of two parts, a numerical and a denominational part. The former is a number whole or fractional, the latter is the name of a thing of the same kind as the quantity to be expressed, and of a certain definite magnitude. Thus three feet, twenty pounds, and sixty seconds, are examples of quantities whose *numerics* are three, twenty, and sixty respectively. The denominational parts, which are necessary for the complete determination of the quantities, are the foot, the pound, and the second. When the numeric is *one*, the quantity is the standard quantity itself, and a quantity of which the numeric is unity is called a *unit*. In the examples given above, the foot, pound, and second are evidently the chosen units. We may use different units of the same kind, as when we speak of one yard, three feet, or thirty-six inches. Here all these express the same quantity, but the numerics are different, because different units are chosen. To express in terms of one U. a quantity which is given in terms of another, we must multiply the original quantity by the number of times which the former U. is contained in the latter. Thus, since there are twelve inches in a foot, to express three feet in inches we must multiply the numeric by twelve, expressing the quantity as thirty-six inches. If any quantities of the same kind are to be compared, we must express both in terms of the same U. Many quantities can be expressed in terms of units of a different kind. In this case we make use of derived units. Thus taking the U. of length as a foot, areas are expressed in terms of the square whose side is unity, and volumes in terms of the cube whose side is unity. Velocities being expressed as so many feet per second involves the time U., and by defining U. velocity as U. space described in U. time, the mathematical treatment of velocities is much simplified. The measurement of force involves, besides the length and time units, another U.—that of mass; and in terms of these fundamental units all physical quantities by proper definition can be expressed. See DYNAMICS, ENERGY, FORCE, VELOCITY, &c.

Unita'rians are properly those who believe in one God; but the name is somewhat misleading, since we might include Jews, Christians, and Mahommedans under this head. It is specially used, however, to distinguish those who may be considered within the pale of the Christian Church, but who reject the doctrine of the Trinity, believing that Christ was man and not God. Thus they are called U. in opposition to Trinitarians, though perhaps anti-Trinitarians would be a more correct name. In considering Unitarianism we shall, first, trace the history of the opinion, and, second, state the form it generally takes in our own time. 1. *History*.—The thing though not the name is found at a very early period of the Christian era. The doctrine was taught by Theodotus, a leather-seller of Byzantium, Artemon of Rome, and Beryllus, Bishop of Bostra. Paul of Samosata, in the 3d. c., is, however, the most famous of the early heretics, some of whom were distinguished as *Patripassians* (q. v.), and others, the great majority, as *Monarchians* (Gr. believers in a 'single rule' or 'government' of the universe). In the *Arianism* (see ARIUS) of the 4th c. we recognise a doctrine not very different from that of the U., but we must come to post-reformation times before the full development of the U. as a distinct sect is seen. It is true that men substantially holding their opinions were never absent from the Church, but during the Middle Ages the central papal force was strong; speculative tendencies were kept within narrow bounds; knowledge was confined to a few; and any departure by a large body of men from the recognised creed of the Church was well-nigh an impossibility. The *Revival of Letters* worked a revolution; and so, after the Reformation, the position of things became entirely reversed. Unitarianism, under the name of Socinianism (see SOCINUS), immediately appeared as a definite creed with a huge body of doctrine. But Roman Catholics and Protestants, if they agreed in nothing else, agreed in persecuting it, and the U. of the 16th c. fled from the tortures of the Inquisition only to find Genevan preachers eager to condemn them to the stake (see SERVETUS). In this extremity they took refuge in Poland, where they soon became a large and powerful sect. They gained over a considerable number of the nobility to their cause, published a large number of writings distinguished by learning and acuteness, and 'for ten years freely pursued their inquiries within the pale of the Reformed Church.' But on the accession of Sigismund III. all was changed; in a short time the U. were driven with ignominy from the kingdom. They were exposed to unusual persecution over the Continent, and by the end of the 17th c. they existed in Transylvania alone. Here they took firm hold, and have continued down to our own time. In 1871 there were in that part of Europe 106 congregations with 50,000 members. In England and America the U. have had brighter fortunes. The period just before and just after the Reformation is disgraced by the burning of several persons who denied the doctrine of the deity of Christ. When these proceedings fell into disuse, Convocation took occasion frequently to condemn the doctrines of the U. During the 18th c., the century alike of indifference and toleration, these doctrines were openly avowed; and a long succession of able writers, Bury, Whitson, Samuel Clarke, Whitby, Emlyn, Priestley, and Belsham argued for this form of Christian doctrine. The present Unitarian chapels in England originally belonged for the most part to the Presbyterian or other Nonconformists who seceded from the English Church on disagreements regarding ecclesiastical government. In point of doctrine these Nonconformists were at first quite as 'orthodox' as the Church which they left, but they were bound by no distinct specific creed, and gradually lapsed into Unitarianism. Their mode of Church government is practically Congregational, since each congregation is independent of all others. In 1871 there were in England and Wales about 380 congregations and mission stations. In Scotland, where Unitarianism has never prospered (though during the 18th c. Socinianism had invaded the National Church to some extent), there are only (1879) eight congregations, and these are for the most part socially powerless. In America the U. are very strong as a separate sect. Those who held the doctrine in England communicated it to America. We may look upon 1756, when Embyn's *Humble Inquiry into the Scripture Account of Jesus Christ* was republished in Boston, as the date of the establishment of Unitarianism as a sect in the New World. It is to a native-born American writer, the famous Dr. Channing (q. v.), that we must look for the consolidation of the American U. His undoubted genius, his fervid eloquence, and still more his high moral character, gave him an almost unbounded influence that lasted longer than his lifetime. Under his leadership several hundred congregations separated themselves from the 'Orthodox

Congregationalists.' In 1871 there were in the States 335 societies with 306 ministers, and in connection with these a large number of active societies and institutes, and several vigorously conducted periodicals. It only remains to add that the greatest names in later Unitarianism are James Martineau (q.v.), President of Manchester New College in London (an institution so free from sectarian bias that it can hardly be exclusively claimed by U.), and Theodore Parker (q. v.) of America. 2. *Doctrine.* It must not be supposed that U. are agreed as to one general body of doctrine. Indeed, there are almost as many differences of opinion among them as among Trinitarians. The name is only a general term for those who, while wishing to retain the name of Christian, refuse to accept the doctrine of the godhead of Christ. Generally, they may be divided into the two following parties. (1.) The conservative U. These receive the general articles of the Christian creed (the Trinity of course excepted). Thus, they believe in miracles, in the resurrection of Christ, in the plenary inspiration of Scripture. Their number is gradually diminishing. In denying the Trinity they principally found upon Scripture argument. (2). The liberal or progressive U. The creed of these U. is purely rationalistic. Christ they consider to have been a mere man—inspired as Socrates was, undoubtedly to a greater degree, but not in a different manner. They reject the miracles and generally the whole supernatural element in Christianity. The Bible they use as a religious text-book, because they consider that it contains the highest expression of the ever-true and permanent religion of humanity. What rites of Christianity (as Baptism and the Lord's Supper) some of them retain, is partly from old association, and partly because they have gradually infused into these a naturalistic meaning. These are probably the majority of U., if not in mere numbers (though perhaps also in this), at least in intellect and position. Although the U. as a separate sect are not prominent on the Continent, this is owing to the fact that their doctrines are so widespread, or the opposition to them is so weak, that they have not been obliged to separate themselves from the Established Churches of the country. The liberal clergy of the Protestant churches of Germany, France, and Holland are really U. in everything except the name. This is not the case in England or Scotland, for the 'Broad Church' party has hitherto rejected special Unitarian doctrines. See Lange, *Geschichte und Lehrbegriff der Unitarier vor der Nicanish. Synode* (Leip. 1831); Meier, *Die Lehre von der Trinitat* (Ham. and Gotha 1844); and J. F. Trechsel, *Die Protest, Antitrinitarier von F. Socin.* For an account of modern Unitarianism, see Beard's *Unitarianism Exhibited* (Lond. 1860); Ellis' *Half Century of Unitarianism* (Lond. 1860); and Orr's *Unitarianism in the Present Time* (Boston 1863).

Uni'ted Presbyte'rian Church. The foundation of this Church was laid in the Secession Church, which was formed on the deposition of Ebenezer Erskine (q. v.) in 1733. The immediate cause of this rupture was the restoration of lay patronage in the Church of Scotland by the Act of Queen Anne (1712). Many of the laity were greatly irritated by the forcible settlement among them of unpopular ministers. Appeals from the Presbyteries which inducted those men to the higher Church Courts had seldom any effect, and at last the General Assembly enacted (1730) that no reasons of dissent against the determinations of Church judicatures should be recorded. This Act Erskine and his friends considered calculated to encourage and increase errors of discipline and doctrine, and being prevented from recording his opposition to it in the minutes of Assembly, he denounced it and the general defections of the Church in his public ministrations, and more particularly in his sermon as Moderator of the Synod of Perth and Stirling (October 1732). Being censured first by the Synod and then by the Assembly, and refusing to submit, he and three other ministers were deposed in 1733, leaving on the table of the Assembly, however, a protest that they *seceded* from the Church because 'the prevailing party in it were carrying on a course of defection from her reformed and covenanted principles.' This was the surface history of the rupture, but the real beginning of the variance is to be traced to the Marrow Controversy (q. v.). Erskine was one of the Marrow Men, who drew up a representation in opposition to the report of the Committee of the Assembly of 1720. But this again was only one indication of the antagonism between the two parties—the Evangelical and the Moderate—which arose in the Church after the Revolution. The Secession Church was formed when the deposed ministers were finally ejected from their churches in 1740.

In 1745 the Secession, which then numbered 46 congregations, formed itself into a Synod; but the prosperity of the church was greatly hindered by a controversy which arose regarding the lawfulness of taking the burgess oath; and a division took place (1747) into the Associate Synod, popularly known as the Burghers, because they allowed their members to take the burgess oath, and the General Associate Synod, or Anti-Burghers, who objected to it. These two sects were again subdivided into four—the former (1799) into the Old Light (or Constitutional party) and New Light Burghers; the latter (1806) into the Old Light and New Light Anti-Burghers. It was the New Light sections of the two parties which united in 1820 to form the United Secession, while the Old Light sections united (1842) as the Original Seceders.

Meantime, in 1752, another Secession had taken place from the Established Church. The Presbytery of Dunfermline had refused to induct a minister who had been presented (1749) to the parish of Inverkeithing, and against whose settlement the majority of the parishioners had protested. The General Assembly (1752) enjoined the Presbytery to proceed with the induction, but six ministers, including the Rev. T. Gillespie of Carnock, absented themselves, whereupon Gillespie was deposed. In 1761 he and Mr. Boston of Jedburgh, and Mr. Collier of Colinsburgh, formed themselves into a presbytery for the purpose of 'giving relief from the yoke of patronage and the tyranny of the Church Courts;' hence the church thus founded was called the Relief Church. By its union with the United Secession in 1847 was formed the U. P. C.

Other schemes of union have since been inaugurated, with more or less of success. In 1863, stimulated by movements in the colonies, a great 'union movement' was begun, to unite the four chief nonconforming bodies in Scotland—the Free Church (q. v.), which had come into existence at the 'Disruption' of 1843, which was the climax of the antagonism between the Evangelicals and the Moderates; the Reformed Presbyterians (see CAMERONIANS); the Original Secession; and the U. P. C. The union between the Free Church and the Reformed Presbyterians was consummated in 1878. That between the Free Church and the U. P. C. is at present postponed, the great obstruction being the 'Voluntary' principle held by the latter. The difference between the two on this point was expressed by one of the Free Church leaders, in a debate on the Union in May 1867, thus:—'We believe that a lawful and scriptural Church Establishment is theoretically possible, whereas our United Presbyterian friends are of opinion that under no circumstances and no conditions ought such an arrangement to take place.' In 1873 a majority of the Free Church Assembly were in favour of the union, but there was a vehement minority, which announced that if the union scheme were carried, they would secede, declare themselves the true Free Church, and claim the whole property of the Church in the civil courts. Under pressure of this policy the union scheme was put aside, and one of 'mutual eligibility' substituted for it. This means that U. P. ministers are eligible as pastors of Free Church congregations, and Free Church ministers as pastors of U. P. congregations; the effect of which is to permit a transfer of ministers from the one Church to the other, and practically to defeat the opponents of union.

The manner in which Voluntaryism has taken an increasingly firm hold on the mind of a certain portion of the people is a curious phase of Scottish church history. The original ground of dissent was a regard for the Church's honour and faithfulness. It was this that led the Seceders of 1733 to separate from the majority of the Church: a passion for Church purity, as well as for Church independence. But as time passed on the latter principle acquired pre-eminence. In the secession of 1752 it is almost entirely the spirituality of the Church, and its freedom from State control, of which we hear. The older seceders regarded the evils against which they kicked as merely abuses in the Church; the later ones came to regard them as more or less essential to the very existence of an Establishment. This was the 'New Light' which came among them, and those who received it became *voluntary.* Now, a great controversy raged at the beginning of this century between this party out-

side the Church, and the spiritual independence party inside the Church, who considered it quite consistent with their principles to remain where they were. Accordingly, when the Free Church was formed by this latter party, its principles were most distinctly and emphatically declared to be opposed to Voluntaryism. And we have seen that this very point was the great obstacle in the way of a union with the U. P. C. But since 1863 'New Light' has been coming to the Free Church, as formerly to the Burghers and Anti-Burghers, and it would seem as if before long the Free Church will be the same as the U. P. C. except in name. Along with the principle of Voluntaryism, there has gradually grown up in the U. P. C. a disposition to allow for differences of opinion within certain definite limits. In 1877 a Committee was appointed to consider the subject of the standards, and in 1878 recommended that a declaratory statement should precede the questions of the formula; this recommendation is still under consideration. In 1878 an important change took place in the curriculum of theological study: instead of an autumnal session of two months, a winter and spring session of six months, and professors were appointed who were relieved of all pastoral duty. In 1878 the U. P. C. numbered 534 congregations, and 173,554 members; and its foreign mission fields were occupied by 63 missionaries. In the same year the total sum raised by the Church for all religious and ecclesiastical purposes was £379,079. See Ferrier's *Memoirs of W. Wilson*, *Lives of the Erskines*, and *Histories of the Secession and Relief Churches*, by the Rev. Dr. Andrew Thomson.

Uni'ted Prov'inces. See NETHERLANDS.

Uni'ted States, The, the 'Great Republic,' occupying the central portion of the continent of N. America, and extending from the Atlantic Ocean to the Pacific, ranks fourth (after the Russian, British, and Chinese empires) among the states of the world in respect of area and of population. It consists of 38 sovereign and independent states, 1 federal district, and 9 territories not yet ranked as states, in consequence either of insufficient population, or from want of conformity to the requirements of the Constitution of the U.S.

Boundaries.—The U.S. are bounded on the N. by British N. America, the boundary-line running through the Strait of Juan de Fuca to the S. of Vancouver's Island, but to the N. of the island of San Juan (see SAN JUAN BOUNDARY QUESTION), striking the mainland at the 49th parallel and running along that parallel to the Lake of the Woods, and thence by a devious route through the great lakes and along the Laurentian watershed to the St. John's and St. Croix rivers and Fundy Bay. The land boundary is a clearing 30 feet wide, with iron mile-posts 4 feet high painted white. The eastern and western boundaries are formed by the Atlantic and Pacific Oceans respectively, the southern boundary by the Gulf of Mexico, the Rio Grande del Norte up to the 32d parallel, and a broken line drawn between the 31st and 33d parallels to the Pacific, separating the U.S. from Mexico. These boundaries do not include Alaska.

Area, Population, and Divisions.—The total area of the U.S., inclusive of Alaska, purchased from Russia in 1867, is 3,603,884 sq. miles. Of these, 1,272,239 sq. miles were actually settled (*i.e.*, possessed two or more inhabitants to the sq. mile) in 1870, as against 508,717 sq. miles in 1820, and 239,935 sq. miles in 1790. The pop. in 1870 amounted to 38,558,371, of whom 4,880,009 were negroes, 63,254 Chinese, and 25,731 Indians. In 1770 the pop. was estimated at 2,312,000, including 462,000 negroes; in 1820 it was 9,633,822, including 1,771,656 negroes; in 1850 it was 23,191,876, including 3,638,808 negroes; and in 1860 it was 31,443,321, including 4,441,830 negroes, 34,933 Chinese, and 44,021 Indians. In 1876 the pop. of Alaska was estimated at 27,500, and the occupants of the Indian territories numbered 383,712, while of undomesticated Indians maintaining tribal relations there were probably about 200,000. The average pop. per sq. mile of the U.S. was, in 1870, 10·70, while the average per sq. mile of the settled districts was 30·2; thus even if we take the settled districts only, the density of population is comparatively very small, that of European Russia being 34 per sq. mile, of Germany 201, of England and Wales 238, and of Belgium 469. Of foreign-born persons settled in the U.S. there were, in 1870, 5,567,229, of whom Austria contributed 30,508, Belgium 12,553, Bohemia 40,289, British America 493,464, Denmark 30,107, France 116,402, Germany 1,690,533, Great Britain and Ireland 2,626,241, Holland 46,802, Italy 17,157, Mexico 42,435, Norway 114,246, Poland 14,436, Sweden 97,332, Switzerland 75,153. The aggregate immigration in 1820-40 was 750,949; in 1841-50, 1,713,251; in 1851-60, 2,598,214; in 1861-70, 2,491,451; and in 1871-78, 2,177,108. During the period covered by these statistics the nationality of the aggregate immigrants was as follows:—English, Irish, Scotch, and Welsh, 4,601,539; German, 2,945,967; French, 309,544; Scandinavian, 323,556; Swiss, 80,719; Italians, 64,881; Austrians, 59,859; Spanish and Portuguese, 36,022; Russians and Poles, 49,343; Dutch, 43,383; Belgians, 22,219; Anglo-Americans, 517,153; West Indians, 61,915; Mexicans, 24,329; Chinese, 216,662; Japanese, 343; and Australians, 8708. The number of emigrants who had returned to the countries from whence they came in the eleven years 1868–78 (both inclusive) was 566,964; the number of immigrants for the same years being 3,199,268—17·7 per cent. therefore returning to their homes. Of the outgoing emigrants one-ninth are from San Francisco, mostly returning Chinese. From New York about three-fifths of the whole take their departure. The effort made in 1879 to restrict the immigration of the Chinese proved abortive, as it was proved to be a violation of treaty, and was, moreover, unnecessary, since the Chinese were largely returning to China. The whole pop. of the U.S. on July 1, 1878, was officially estimated at 47,874,485.

In the following table the states in which slavery existed up to the general emancipation (December 18, 1865) are in italics. The district of Columbia, formed in 1790, is called federal, because it belongs to and contains the capital of the whole Republic. The states which joined the Union after its formation by the original 13 states in 1787, are followed in the table by the respective dates of their admission.

STATES.	Area in sq. miles	Pop. in 1870.	Estimated Pop. in 1879.	CAPITALS.
FEDERAL DISTRICT—				
Columbia	64	131,700	195,000	Washington.
NEW ENGLAND—				
Maine (1820)	35,000	626,915	630,000	Augusta.
New Hampshire	9,280	318,300	318,000	Concord.
Vermont (1791)	10,212	330,551	330,000	Montpelier.
Massachusetts	7,800	1,457,351	1,821,000	Boston.
Rhode Island	1,306	217,353	290,000	Providence and Newport.
Connecticut	4,750	537,454	620,000	Hartford.
NORTHERN—				
New York	47,000	4,382,759	4,905,000	Albany.
New Jersey	8,320	906,096	1,130,000	Trenton.
Pennsylvania	46,000	3,521,951	4,125,000	Harrisburg.
Ohio (1802)	39,964	2,665,260	3,120,000	Columbus.
Michigan (1837)	56,451	1,184,059	1,512,000	Lansing.
Wisconsin (1848)	53,924	1,054,670	1,409,000	Madison.
Minnesota (1857)	83,531	439,706	753,000	St. Paul.
MIDDLE—				
Delaware	2,120	125,015	140,000	Dover.
Maryland	11,124	780,894	850,000	Annapolis.
Virginia	38,348	1,225,163	1,295,000	Richmond.
W. Virginia (1863)	23,000	442,014	508,000	Charleston.
N. Carolina	50,704	1,071,361	1,160,000	Raleigh.
Kentucky (1792)	37,680	1,321,011	1,490,000	Frankfort.
Tennessee (1796)	45,600	1,258,520	1,385,000	Nashville
SOUTHERN—				
S. Carolina	34,000	705,606	951,000	Columbia.
Georgia	58,000	1,184,109	1,372,000	Atlanta.
Florida (1845)	59,268	187,748	243,000	Tallahassee.
Alabama (1819)	50,722	996,992	1,148,000	Montgomery.
Mississippi (1817)	47,156	827,922	986,000	Jackson.
Louisiana (1812)	41,346	726,915	964,000	New Orleans.
Texas (1845)	274,356	818,759	1,583,000	Austin.
CENTRAL—				
Indiana (1816)	33,809	1,680,637	2,045,000	Indianopolis.
Illinois (1818)	55,410	2,539,981	3,486,000	Springfield.
Iowa (1846)	55,045	1,194,020	1,673,000	Des Moines.
Missouri (1821)	65,350	1,721,295	2,305,000	Jefferson city.
Arkansas (1836)	52,198	484,471	681,000	Little Rock.
Kansas (1861)	81,318	364,399	707,000	Topeka.
Nebraska (1864)	75,995	122,993	485,000	Lincoln.
Colorado (1876)	104,500	39,864	209,000	Denver.
WESTERN—				
California (1850)	188,981	560,247	756,000	Sacramento.
Oregon (1859)	95,274	90,923	112,000	Salem.
Nevada (1864)	104,125	42,491	86,500	Carson city.
	2,084,031	38,281,205	47,870,500	

The following is a table of the Territories, exclusive of Alaska (q. v.) and of the Indian Territory (q. v.).

Territories.	Organised.	Area in sq. miles.	Pop. in 1870.
New Mexico	1850	121,201	91,874
Utah	1850	84,476	86,786
Washington	1853	69,994	23,955
Montana	1864	143,776	20,595
Idaho	1863	86,294	14.999
Arizona	1863	113,916	9,658
Wyoming	1868	97,883	9,118
Dakota	1861-68	155,932	14.181
		873,472	271,166

Physical Aspect.—The two great mountain systems of the U. S. are the Appalachians (q. v.) and the Rocky Mountains (q. v.). The former extend from the mouth of the St. Lawrence to the mouth of the Mississippi—a distance of 1300 miles—and at the south bend inland, leaving the wide and rich seaboard of Virginia, the Carolinas, Georgia, Alabama, and Florida. This maritime region includes all the older states, and its inhabitants still amount to one-third of the whole. As far S. as the Hudson River it is hilly; thence, as far as the Alleghanies extend, its surface is divided between a plain and a mountain-slope, the base of which appears to have been the shore of an ancient sea. The most fertile part of this slope is between Long Island and the Potomac. The coast to the Mississippi is sandy throughout; from Long Island to N. Carolina it is marshy only close to the sea, but farther S. the seaward half of the plain is covered with swamps. The Appalachians form the watershed between the rivers draining into the Atlantic and the tributaries of the Mississippi, though some of the former may be said to rise on the inland side of the mountains, and to force a passage through them to the sea. The principal rivers falling into the Atlantic are the Penobscot, Kennebec, Merrimac, Connecticut, Hudson, Delaware, Susquehanna, Potomac, Rappahannock, James, Roanoke, Pedee, Santee, Savannah, and Altamaha. The Chattahoochee and the Flint River joining form the Appalachicola; the Alabama and Tombigbee, the Mobile; these drain into the Gulf of Mexico E. of the Mississippi. The great central plains and prairies between the Appalachians and the Rocky Mountains are drained almost entirely by the Mississippi (q. v.) and its affluents, chief of which are the Ohio, Tennessee, Missouri (q. v.), Arkansas, and Red River. The only other river of great importance flowing into the Gulf of Mexico is the great boundary river, the Rio Grande del Norte. The streams flowing N. are trifling, the principal being the Red River of the North, which flows into Lake Winnipeg. Almost the whole of the Mississippi basin consists of open, rolling prairies (see PRAIRIE), while, on the other hand, almost all the country beween the Appalachians and the Atlantic was originally more or less thickly wooded. Between the Rocky Mountains and the Pacific Alps, called Sierra Nevada (q. v.) in California and Cascade Range further N., lies a rainless region, mostly S. of 40° N. lat., with an average elevation of 5000 feet above the ocean, great part of it communicating, not with the sea, but draining into salt lakes and marshes. Except where irrigated, this plateau is utterly unproductive. To the N. it is drained by the Columbia, with its tributary the Snake River, which forces its way through the Sierras to the Pacific; while in the southern portion the Colorado and its affluents, after flowing through frightful cañons 3000–5000 feet below the surface of the plateau for some 600 miles, forms a delta at the head of the Gulf of California. The Great Cañon of the Colorado is more than 300 miles long. Between the Sierras and the ocean stretches the comparatively narrow but rich and beautiful sea-coast known as the Pacific Slope, drained by the Columbia, the Klamath, the Sacramento, and the San Joaquin, along with numerous smaller streams. The 'Great Divide,' or watershed, is in Montana and Wyoming Territories, whence flow the Missouri, Columbia, and Colorado. In this wild region the U.S. Congress set apart in February 1872 the 'Yellowstone National Park,' a tract 64 × 55 miles in extent (area, 3575 miles) in the N.W. of Wyoming. The region, while mostly unfit for agriculture and mining, contains more natural marvels than can be found elsewhere. There are hot springs with their basins encrusted with calcareous spar, steam-jets, geysers, mud volcanoes, waterfalls, caves with stalactites and stalagmites, eroded columns, statues, castles, cathedrals, &c., and a large lake swarming with fish. The valley of the Upper Yellowstone (q. v.), abounds in these wonders. At some points it flows through basaltic arches and past seeming ruins. The Column Mountain has numberless monuments and towers, the result of erosion and upheaval. The geysers of Fire Hole basin, on the main fork of the Madison river, surpass those of Iceland, and there are boiling springs, steam-jets, and mud-volcanoes. Colorado, about the 38th and 39th parallels, has many natural wonders; its famous parks, the beds of vast ancient lakes, its coloured rocks, its 'Garden of the Gods,' entered by a gateway of red and yellow sandstone 300 feet high, walled in by sandstone, with its statues, towers, cathedrals, and caves, while Pike's Peak, 14,336 feet high, forms the background.

Seaboard, Islands, and Lakes.—The shore line of the U. S. extends to 12,609 miles—6861 miles on the Atlantic, 3467 on the Gulf of Mexico, and 2281 on the Pacific, but this is indefinitely increased by the navigable lakes and rivers. On the great lakes, Buffalo, Chicago, Cleveland, Detroit, and Milwaukee are important seaports. The Atlantic coast abounds in bays and sheltered inlets, but the Pacific coast is badly provided with harbours. The chief islands of the Atlantic coast are Nantucket, Martha's Vineyard, Long Island, Manhattan and Staten Islands, Roanoke Island, Helena, and the Florida Keys. In the Gulf of Mexico are the Tortugas, St. George's, Santa Rosa, the Chandeleur Islands, Galveston, and Padre Island. On the Pacific coast are the Santa Catalina and Santa Cruz groups, and San Juan. Lakes Superior, Huron, St. Clair, Erie, and Ontario are shared by the U.S. and the Dominion of Canada, but Lake Michigan is wholly within the U.S. Other notable lakes are Moosehead in Maine; Champlain, George, and Oneida in New York; Okeechobee in Florida; Caddo and Portchartrain in Louisiana; Winnebago in Wisconsin: Spirit Lake in Minnesota; Devil's Lake in Dakota; Yellowstone in Wyoming; Utah and Great Salt Lake, in Utah; Pyramid in Nevada; Tulare, Mono, Tahoe, and Clear Lakes in California.

Climate, and Hygienic Conditions.—The vast area of the U.S. necessarily exhibits a great variety of climate. New York has the winter of Copenhagen and the summer of Rome, the minimum range of the mercury being 5° in winter, and the maximum 98° in summer. The states bordering on Canada exceed both of these extremes, but throughout the middle states, lat 37°–41°, the climate is agreeable and often delightful throughout most of the year. The main peculiarity of the N. American seasons is the almost total absence of spring. Mason and Dixon's Line (q. v.), with its westerly extension along the Ohio, Mississippi, and Missouri, has an historical interest, but is also of climatic importance in the geography of the Cis-Missouri states. N. of it, sledges are in frequent use during winter; S. of it, they are seen rarely. To the N. the productions are those of the temperate zone, and the states were always free; to the S., the country, the old home of slavery, becomes more and more tropical as we advance. From meridians 98° to 100° the climate is still variable from year to year, seasons of rain and plenty being followed by others in which drought is the forerunner of scarcity. But the planting of forest trees and the cultivation of the soil, at first by irrigation, has increased the amount of rainfall, and within the next twenty years the region W. of 100° W. long. will yield the greatest crops on record anywhere. In 1869, '70, '71, and '72, in Weld Co., Colorado, between meridians 104° and 105°, 312, 316, 319, and 322 bushels of shelled Indian corn were raised to the acre. Along the Pacific seaboard, especially in California, the climate resembles that of S. Europe. The isothermal lines, roughly stated, show a mean temperature of 72° for Florida, the Gulf Shores, and Arizona; of from 52° to 60° for S. of Pennsylvania, Virginia, the N. border of the Carolinas, Tennessee, Missouri, Kansas, S. of Utah and Nevada, and the greater part of California; from 44° to 52° for Massachusetts, New York, Michigan, Northern Illinois, Nebraska, Oregon and Washington territory; and from 36° to 44° for Maine, parts of New Hampshire and Vermont, Wisconsin, Minnesota, the whole crest of the Rocky Mountains, and parts of Oregon and California along the Sierras. The annual rainfall ranges from 56 to 64 inches in the S. of Florida and along the N.W. Pacific coast; 44 to 56 inches over the New England coast and the greater part of the Southern States, while in New York, Pennsylvania, Illinois, &c., it is 32–44 inches. In Texas, the Indian territory, E. Kansas and Nebraska, Dakota and Minnesota, and W. California, it is 20–32 inches, while in the tract between 98° and 118° it ranges from 18 to 4 inches. In 1860–1870, the death-rate of the whole U.S.

was 1·28 per 100. Malarial diseases prevail in the lowlands of most of the Southern States, as also in the new and marshy portions of the W. States below 40° N. lat. In 1878 an outbreak of yellow fever at Memphis, Vicksburg, and New Orleans carried off 12,000 persons in twelve weeks. Consumption and chest diseases prevail in the New England and in the Middle States. Minnesota, Colorado, California, Arkansas, Georgia, and Florida are favourite resorts for persons with weak lungs. On the whole, the climate of the U.S. may be called healthy, malarious and deadly spots being very few; while certain districts, especially of Florida, the central plains, and the Pacific coast, are among the most salubrious in the world.

Geology and Mineralogy.—Geologically as well as geographically the U. S. are divided into two great sections by the Rocky Mountains, along whose whole extent, in a wide belt from N. to S., Cretaceous formations predominate, with occasional stretches of Carboniferous strata. Tertiary formations embrace almost the whole of the basin between the Rocky Mountains and the Pacific Alps, broken by igneous rocks in Washington territory and Oregon, and Metamorphic strata along the Sierras; in the E. section Tertiary formations stretch along the coast from the Rio Grande almost to the Hudson. Metamorphic, igneous, and Devonian rocks prevail in New England, and along the shores of the great lakes the Middle Devonian or Old Red Sandstone. Older Palæozoic groups occur in Wisconsin, Ohio, and Tennessee, and run side by side with Metamorphic strata along the Appalachians, while a large proportion of the interior is occupied by great Carboniferous deposits. Anthracite coal occurs in New England, and the basins of Pennsylvania embrace about 472 sq. miles, and extend to a depth of from 60 to 100 feet. The Appalachian coal-fields embrace an area of over 59,000 sq. miles, those of Michigan 6700 sq. miles, those of Illinois 36,000 sq. miles, and those of Missouri 84,300 sq. miles. These great beds are said to be twenty times richer than all the coal-fields of Europe put together. The total production of coal in the year 1877 was 52,101,339 tons; Pennsylvania alone in 1877 raised 22,816,359 tons of anthracite coal, and employed 66,842 men in and about the mines. The aggregate yield of petroleum in the year 1870 was 181,263,502 gallons, of which W. Virginia produced 8,000,000, Ohio 2,000,000, and Pennsylvania the rest. In 1878 the production was 607,200,000 gallons, and the export 339,000,000 gallons. The ores of iron abound in the States, and include all known ores. The ore-beds most largely worked are in Connecticut, New York, New Jersey, Pennsylvania, Ohio, Michigan, Tennessee, W. Virginia, Alabama, Georgia, Wisconsin, Minnesota, Dakota, Columbia, Utah, and California. Most of these beds are inexhaustible. The amount of pig-iron produced and marketed in 1870 was 2,066,594 tons, and the quantity could be increased tenfold. Copper ore yielding 90-95 per cent. of pure metal is found in N. Michigan, and ores less rich in Vermont, Connecticut, N. Carolina, Tennessee, Columbia, and California; zinc in New Jersey, Pennsylvania, Arkansas, and California; lead ores (galena) in Minnesota, Iowa, Columbia, Wyoming, Utah, Dakota, Nevada, &c.; tin in California, and a little elsewhere; quicksilver (78,600 flasks in 1877) in California and Nevada. Gold and silver are widely distributed, 14 States and territories reporting them; but California, Nevada, Columbia, Montana, Dakota, Arizona, and Utah produce 29·30 of the whole, and Nevada alone about one-half. Nevada, Columbia, Utah, and Arizona yield more silver than gold. The total bullion production of 1878 was $96,952,421—gold $50,226,107; silver, $46,726,314.

Flora and Fauna.—The indigenous plants of the U. S. are estimated at about 5000 species, California alone producing at least 2500. The potato, the tobacco-plant, and maize, now so familiar in Europe, have all been introduced from the U. S. or Mexico. The U. S. are especially rich in valuable timber-trees, of which no less than 120 species, growing in sufficient quantities to be of commercial importance, attain a height of 100 feet and upwards. Of these 12 species reach an altitude of 200 feet, and 5 or 6 exceed 300 feet. Hickory, magnolia, liquid-amber, sassafras, and sequoia trees (to which species belong the giant trees of California), found only in a fossil state in the Old World, abound in the U. S., as well as palmetto, tulip-tree, cypress, cotton-wood, live-oak, and other oaks, and a number of trees more or less closely resembling the common species of Western Europe, to which the same names have been given. For the zoology of the U. S. see AMERICA, NORTH. So far as they have as yet been described and classified, the Vertebrata are estimated at 2249 species, the Mollusca at about 1434 species, while an eminent entomologist considers that there are probably over 50,000 species of insects.

Agriculture and Live Stock.—The public lands held by the U. S. in 1878 amounted to 1,814,772,648 acres, of which 724,311,477 had been surveyed, and 1,090,461,171 acres were unsurveyed. Of the latter, 379,529,600 were in Alaska. About 8,000,000 acres are sold annually. When surveyed, they are divided into townships, 6 miles square, containing 36 'sections' of 640 acres, which again are divided into half and quarter sections, and offered for sale, generally at $1·25 per acre, one section being reserved in each township for common schools. The average size of farms is 153 acres, and the total extent of area cultivated was 121,300,000 acres in 1878. The cereal crop most largely produced is Indian corn, which is grown in almost all the states, but especially on the plains about the Ohio, Mississippi, and Missouri, and in Texas. In 1878 the number of bushels produced was 1,371,000,000, while wheat, which is mainly cultivated in the Northern and Central States, California, and Oregon, reached 422,000,000 bushels. There were 406,394,000 bushels of oats, 1,371,000,000 of corn, 35,600,000 of barley, 22,100,000 of rye. The Southern States raise large quantities of cereals, especially maize, but the staples of the northern tier (Maine, Kentucky, Maryland, and N. Virginia) are tobacco, maize, and wheat; of the southern tier (N. Carolina, S. Carolina, Florida, Alabama, Mississippi, Louisiana, Texas, Arkansas, and Tennessee) cotton and maize, to which S. Carolina, Georgia, and Louisiana add rice, Florida oranges, and Louisiana and Texas sugar. The production of tobacco in 1877 reached 490,000,000 lbs., and the export of cotton from 1st September 1877 to 1st September 1878 amounted to 3,558,560 bales. The number of acres under Indian corn was, in 1877, 50,369,113; under wheat, 26,277,546; under oats, 12,826,148; under other cereals, 3,677,479; under potatoes, 1,792,287; under hay, 25,367,708 (31,629,300 tons); and under tobacco, 387,142. In 1877, 88,250,000 lbs. of rice were produced altogether in the Southern States; of maple sugar 41,000,000 lbs., principally in the Northern States; while of cane and sorghum sugar 229,800 hogsheads, and of molasses 26,347,079 gallons, principally in the Southern States. The Northern States, and especially New York and Vermont, furnish immense quantities of dairy products, and there is now a large export trade in meat (see TEXAS). In 1878, 4,500,000 acres were devoted to fruit culture, and the value of the apple crop was $138,216,700, of pears $14,130, peaches $46,135,000, grapes $2,118,000, strawberries $3,000,000, and other fruits $10,432,000. The preserving and 'canning' of fruit has of late years become an important branch of trade. In 1879 there were in the U. S. 10,618,800 horses, 21,077,100 cattle, 12,206,600 milch cows, 38,482,600 sheep, and 34,331,400 pigs. The total estimated value of farm animals in 1878 was $1,845,584,863.

Industries.—At the census of 1870 there were in the U. S. 252,148 manufacturing establishments, employing 2,053,996 hands, and the capital employed amounted to $2,118,208,769, the wages paid to $775,584,343, and the total produce to $4,232,325,442. There were 956 cotton-mills, 2891 woollen mills, and the production of carpets alone amounted in 1875 to $6,475,200. The production of wool increased from 75,000,000 lbs. in 1861 to 207,000,000 lbs. in 1878, and now constitutes 4·5 of the whole consumption. In 1862 American mills used 130,644,720 pounds; in 1878, 249,149,004 pounds. In 1872 woollen goods valued at $53,408,431 were imported; in 1878, $25,220,154. In 1877-78 American mills consumed 1,554,974 bales of cotton (699,736,247 lbs.), against 3,558,569 bales exported. In 1878 there were 698 blast furnaces, 3403 rolling mills, 4514 single puddling-mills, 11 Bessemer steel works, 22 Bessemer converters, 14 open-hearth steel works, 38 crucible cast-steel works, &c. In the year ending 30th June 1878, 22 iron vessels were built in the ports, with a tonnage of 26,960. In 1877, during which year 446 furnaces were out of blast, the total production of pig-iron was 2,066,594, and in 1878 that of steel-rails was 682,776 tons, of steel ingots 637,342 tons, and of iron rails 332,540 tons. Out of 716 furnaces only 248 were in blast in January 1879. Silk goods are manufactured to the extent of $23,000,000, and $19,000,000 are imported. Besides textiles and hardware, the principal manufactures are bleaching and dyeing, books, bricks, carriages, and cars, clothing, flour and other food products, furniture, glass, hats, hosiery, leather

in all forms, rubber goods, liquors, machinery—agricultural and other; musical instruments, oils of all kinds, paints, paper, wood manufactures, sewing machines, sugar-refining, cigars, &c. The river and coast fisheries are very productive; the canned oyster, lobster, and salmon trade has of late years become exceedingly extensive.

Commerce and Communication.—The commercial marine of the U. S. was greatly diminished during the war, but is now increasing, and in 1878 numbered 25,264 vessels of 4,212,765 tons, and of these 4472 were steamers of 1,167,678 tons. In the year ending 30th June 1878, of the vessels that entered the ports 10,594 of 3,642,417 tons were American, and 20,202 of 10,821,387 tons belonged to other countries; while of those that cleared, 10,872 of 3,872,203 tons were American, and 20,492 of 10,935,328 tons belonged to other countries. Besides these there entered of coasters 74,843 of 34,142,785 tons, and cleared 74,219 of 32,906,672 tons. The total imports and exports for the year ending 30th June 1878 (exclusive of bullion and specie), were $437,051,532—less foreign exports, $14,156,498 = $422,895,034 and $680,709,268 respectively. The imports have declined since 1875, and still more since 1873, when they stood at $624,689,727. The exports, however, were larger in 1878 than in any previous year, and show an increase of $411,319,368, or 153 per cent., since 1868. Agricultural produce is of course the staple material of export. Cereals stand first in the list, and comprise mainly wheat, maize, and rye; they are followed by cotton, tobacco, sugar, provisions, iron and steel, petroleum, leather, and live-stock. Of the articles the export of which has greatly increased during the last decade, the chief are bread and bread-stuffs (value 1878, $181,777,841), provisions ($123,556,323), coal-oil and petroleum ($46,574,974), iron and steel, and manufactures of these ($15,882,508), cotton manufactures ($11,438,660), leather and leather goods ($8,080,030), live-stock ($5,844,653), oil-cake ($5,095,163), and farm implements ($2,575,197). There has been, on the other hand, a striking decrease in the imports of manufactured cottons (decrease since 1873, $16,120,287), of raw wool ($12,070,923), of silks ($10,052,063), of railroad bars ($19,740,172), of iron in pigs ($12,491,232), of cutlery ($6,786,910), tin and tin-plates ($5,090,783), of clocks and watches ($2,462,243), and of tea ($8,806,002). The import of railroad bars actually decreased from $19,740,702 in 1873 to $530 in 1878. The decrease of imports of sugar, syrup, and molasses from 1873 to 1878 is $15,080,335. More than half of the exports ($460,136,521) are absorbed by Great Britain and Ireland (£19,356,796 worth of wheat, flour, and meal alone in 1878), and the British colonies and possessions, and the rest chiefly to France, Germany, Spain and its colonies, China, and S. America. The internal commerce and communication of the U. S. is carried on by means of the great navigable rivers and canals and an elaborate system of railroads. There are 3188 miles of canals, and on the 1st January 1878 there were 79,208 miles of railway open for traffic, while 2688 miles additional were constructed in the course of 1878. There were, in 1878, 37,345 post-offices in the U. S., which transmitted in that year 689,580,670 letters and 170,015,500 post cards, besides other communications. At the same date there were 9500 telegraph offices, with lines 110,000 and wires 242,000 miles long, 21,000,000 messages being transmitted in the course of the year. There is more travelling in the U. S. than in any other country, and in no country is travelling made so comfortable. The river steamboats are provided with a luxurious saloon almost as long and wide as the vessel itself; the railway carriages, furnished with every necessary, communicate with each other like a suite of rooms. In the new States the country roads are bad; in swampy places logs are laid across to form 'corduroy' roads over which vehicles jolt at the slowest rate. The hotels and boarding-houses, the largest and most perfect in the world, are chosen as permanent residences by many families, as well as temporary homes by the hundreds of thousands of guests from all parts of the world. There is some difficulty with servants, but perhaps not more than in Great Britain.

Ethnology.—For the aboriginal races see INDIANS, AMERICAN, and separate articles on the principal tribes. Statistics of the foreign elements in the population of the U. S. are given above. How the fusion of these heterogeneous, and in some cases mutually antagonistic, masses into one national whole is to accomplish itself, is one of the most interesting points of speculation in connection with the future of America. Until the beginning of the present century the white population was, with the single exception of New York, where the Dutch element prevailed, almost exclusively of British descent, but since then it has received large and varied accessions. The negro population is mostly confined to the Southern and Middle States. Germans are distributed over all the Northern States, but especially in and around New York, along the S. shore of Lake Erie and in the North-Western States, around St. Louis, and in parts of Ohio, Indiana, Illinois, and Iowa. The Irish population is densest in New York, S. New England, New Jersey, and E. Pennsylvania, but is also diffused through the whole Northern States. English immigrants are very numerous in New England, New York, New Jersey, and Pennsylvania, and to some extent along the lake shores. The Welsh seek the mining and dairy districts. British Americans are most numerous in New England and the North tier of States; and by far the greater proportion of the Scandinavian settlements are W. of Lake Michigan. A further admixture of race has resulted from annexation; the French came in with Louisiana, and Spanish and Mexican with the admission of Florida, Texas, New Mexico, and California. The Chinese and Japanese are most numerous on the Pacific Coast, but some are found in the States E. of the Rocky Mountains. Their whole number is not probably over 150,000. English, which is gradually absorbing all other languages, is used in the State legislatures, schools, and courts of law, but some of the newspapers are published in German, French, and Scandinavian, in the districts most densely occupied by these nationalities. For an account of the linguistic peculiarities resulting from natural associations and the fusion of diverse tongues, see the article AMERICANISMS.

Religion and Education.—The Constitution expressly forbids any state support to religion, which it leaves entirely free. The consequence of this perfect freedom has been a voluntaryism in religion which has certainly produced excellent results in the Republic. The religious denominations are divided into groups, which, though comprising several distinct bodies, will probably eventually come together. The Methodist group is numerically the largest, embracing in its various organisations in 1878 about 3,400,000 members, and an adherent population of about 13 millions; the Baptist group comes next, and includes about 3,000,000 members and 12,500,000 adherents. The Mennonites, who are migrating from Russia in such numbers, belong to this group. The Presbyterian group, with 1,250,000 members and 6,000,000 adherents, comes next, and the Roman Catholics follow with an adherent population of 5,700,000. Next to these are the Lutherans, largely Germans or Scandinavians. They have 650,000 members and 3,000,000 adherents. The Congregationalists and the Protestant Episcopal Church are nearly equal in numbers, having 420,000 and 400,000 respectively, and adherent populations of about 1,800,000 and 1,700,000. The other denominations are much smaller. The School system in the U. S. is not perfect, but it affords the means of universal elementary instruction. In 1876 the school population was 14,222,991; of these, 8,363,738 were enrolled in the public schools, and 550,000 more in private schools; 4,066,848 were reputed in daily attendance; 249,281 teachers instructed them (96,161 males and 136,542 females); the public school income exceeded $88,000,000, and the annual expenditure $84,000,000. The Permanent Public School funds were $98,754,870. The same year there were 151 normal schools, with 33,921 pupil-teachers; 137 commercial and business colleges, with 25,000 students; 130 Kindergartens, with 4090 pupils; 1559 schools for secondary instruction, with 142,872 students of both sexes; 356 universities and colleges, with 56,481 students; 343 professional and scientific schools, with 24,697 students; 133 schools for deaf mutes, blind, idiots, &c., with 20,000 pupils; and 385 orphan asylums, with 47,439 inmates. The universities and colleges best known are Harvard (q. v.), Yale (q. v.), Princeton (q. v.), Columbia (q. v.), Amherst (q. v.), Cornell (q. v.), University of Michigan, La Fayette (q. v.), Brown (q. v.), Williams (q. v.), Bowdoin, Vassar (q. v.), Wells, Wellesley, and Smith, the last four being for women only. There were, in 1876, 3723 public libraries in the U. S., containing 12,376,473 volumes and 2,500,000 pamphlets. The periodical press is the most prolific in the world (see NEWSPAPERS), and public lectures are delivered everywhere.

Army and Navy.—The enormous military establishments necessitated by the Civil War have been gradually reduced to

very small limits. Whereas in May 1865 the U. S. forces, including the volunteer and regular army, amounted to 1,000,000 men, it is now provided that there shall not at any time be more than 25,000 enlisted men in the service. In 1878 the U. S. army had a total strength of 27,161, including 2161 officers. These are distributed in 5 regiments of artillery, 10 of cavalry, and 25 of infantry, besides a corps of engineers. The higher officers are a general, a lieutenant-general, 3 major-generals, 14 brigadier-generals, 67 colonels, 86 lieutenant-colonels, and 242 majors. The President is, *ex officio*, commander-in-chief of the army, and of the State militia, which comprises (1878) 8101 officers and 145,219 men, and which can be put on a war footing of 3,434,058. The period of enlistment in the regular army is five years, and all citizens, with certain exceptions, are liable to service in the militia between the ages of eighteen and forty-five. There is a military academy at West Point, where the number of cadets in 1875 was 312. The navy consisted in 1878 of 23 ironclads, for the most part monitors, along with 2 or 3 torpedo ships, 68 steamers not ironclad, and 22 sailing vessels; total number of cannons, 1108. The total force was 7500 strong. There are 10 naval yards, the largest being at Portsmouth, Charleston near Boston, Brooklyn, and Philadelphia. The naval academy (in 1878, 312 midshipmen) is situated at Annapolis.

Constitution, Government, and Finance.—In its own local affairs each State has paramount authority, and is governed according to a Constitution of its own. These constitutions are all constructed upon one model, but differ in details, such as the method of electing the Governor, who is sometimes chosen by the people, sometimes by the legislature. By the constitution of 1787 the powers of the state federal are vested in three institutions, distinct and independent of each other,—namely (1) the presidency, representing the executive; (2) Congress, entrusted with the legislative power; and (3) the Supreme Court, head of the judicature. The Central Government controls the imposition and collection of taxes and duties; the coinage of money; the management of the army and navy; all dealings with foreign powers, &c. The Congress is composed of two Houses, the upper called the Senate, the lower the House of Representatives. To the Upper House each state, whatever its size, sends two senators, chosen by the State Legislature for a term of six years. The members of the House of Representatives are chosen usually by Congressional districts for a term of 2 years, the ratio being fixed after each national census, and each State sending according to its population. The present ratio is 142,000, and the number of members 293. There is also a delegate from each territory, but he has no vote. The President, who holds office for four years, is chosen indirectly—*i.e.*, with the intervention of an electoral college, consisting of electors from each state equal in number to the Senators and Representatives of that state put together. These electors are chosen in most cases by the citizens of the state, in a few by the State Legislature. A Vice-President, who presides in the Senate, and succeeds to the Presidency if the President dies during his term of office, is elected on the same ballot. The President possesses a veto on all measures passed in Congress, but a measure sent back and again passed by a majority of two-thirds in each House is carried over his veto. The Supreme Court consists of a chief justice appointed by the President for life, and eight associate justices. It has the right of deciding in all cases in which the enactments of Congress clash with those of the individual states. There are also 65 district courts, and 9 circuits in which circuit courts are held by the several justices of the supreme court. The executive departments are seven in number:—the department of State, of the Treasury, of War, of the Navy, of the Interior, of Justice, and of the Post-Office. The revenue of the U.S. is raised almost entirely from customs duties and indirect taxes on property, manufactures, &c. Direct taxes are seldom resorted to, owing to a constitutional provision that such taxes shall only be laid on the states in proportion to their population; so that a high rate of taxation would ruin the poorer states, while a low rate would produce a very inadequate result from the richer states. The budget revenue for the financial year 1878–79 is estimated at $269,250,000, viz., from customs $133,000,000, from internal revenue $120,000,000, and the sale of public lands $1,000,000. The expenditure for 1877–78 amounted to $236,964,000, $16,551,323 going to the civil list, $35,397,164 to public works, &c., $27,147,019 to pensions, $32,154,148 to the War Department, $17,365,301 to the Navy, $102,500,875 to the interest on the public debt, including the 'Pacific Railroad Bonds,' and the remainder to foreign intercourse, Indian affairs, &c. The revenue for 1877–78 was $257,446,776. Ever since the year 1865 the revenue of the U.S. has largely exceeded the expenditure, and the income tax has been abolished and other taxes reduced. The aggregate sum expended on custom-houses, post-offices, mints, and hospital buildings in the period 1789-1860 was $28,640,170, and in 1861–76 $41,269,746. The public debt in the year 1790 amounted to $75,463,476; at the conclusion of the English war in 1816 it had risen to $127,334,934; in 1835 it had all been paid off. Before the Mexican war, in 1844, it was again $26,143,996; in 1849 it stood at $64,704,693; in 1860 at $64,769,703; in 1861 at $90,867,828; in 1862 it had risen to $524,176,412; and as the Civil War proceeded it advanced with gigantic strides, until in 1866 it stood at $2,773,236,174. Since then it has steadily decreased to $2,028,648,111 at January 1, 1879. The State debts of all the States and Territories were, on 1st January 1877, $345,197,000. The paper dollar or 'greenback,' which was made a legal tender for all purposes except customs' duties and the payment of interest and principal of the public debt, has fluctuated greatly in value since 1862, being at one time (in 1864) worth only 1s. 6d. in gold, but it has gradually appreciated in value till, with the rapid funding of the debt at 4 per cent., there was a resumption of specie payments, January 1, 1879, and the greenbacks at once advanced to par with gold (4s.). By some unwise legislation in February 1878 it was attempted to make the silver dollar of 412½ grains (900 fine) pass for 100 cents; but the rapid depreciation of silver has rendered this impracticable, and the Bland Silver Act is destined to be speedily repealed.

For statistical information see F. A. Walker's elaborate *Ninth U. S. Census* (3 vols. Wash. 1872, &c.), and his *Statistical Atlas of the U. S.* (Wash. 1874); also the *Quarterly* and *Annual Reports of the Bureau of Statistics*; *First Century of the American Republic* (New York 1876); Vernon's *American Railroad Manual* (New York and Philad. 1877); F. Ratzell's *Vereinigten Staaten* (1st vol. Mun. 1878). On the Constitution see Andrew's *Manual of the Constitution of the U.S.* (New York 1874); Paschal's *Constitution of the U.S.* (Wash. 1868); Seaman's *American System of Government* (New York 1871); Gillet's *Federal Government* (New York 1871); De Tocqueville's *Democracy in America* (new ed. Lond. 1875), and T. D. Woolsey's *Political Science* (2 vols. Lond. 1878).

History.—Passing over the undoubted discovery of New England by Norsemen in the 10th c. as fruitful of no historical results, the first European people in modern times to effect settlements within the present area of the U. S. were the Spaniards, but the honour of laying the broad foundations of the American colonies belongs to England. The settlement of Virginia, properly so called, began in 1607, the colonists being almost exclusively English, and for the most part needy and worthless adventurers. Subsequently, large numbers of debtors and criminals were sent thither, as well as some of a better class. Henry Hudson, an English sailor in command of a Dutch expedition, in 1609 explored the regions about the great river which now bears his name, and the New Netherlands, as they were then called, were settled by the Dutch in 1613. In 1620 the Pilgrim Fathers, who under the guidance of John Robinson (q. v.) had fled from Lincolnshire to Leyden twelve years before, landed at Plymouth and commenced the settlement of New England. The first body of colonists landed at Massachusetts Bay in 1630, was, for the most part, composed of Puritans of higher social position than the Pilgrims of Plymouth. The intolerance of the Massachusetts colony (not the Plymouth) drove Roger Williams and others to found Rhode Island in 1636, as a refuge for persons 'distressed for conscience,' and thither Baptists, Quakers, and other sects resorted. In 1634 Cecil Calvert, Lord Baltimore, organised the colony of Maryland, offering religious toleration to men of all creeds. The settlement of Connecticut and New Haven, both offshoots from Massachusetts, took place in 1634 and 1638. New Hampshire and Maine, though first settled in 1623, were reorganised, the latter as a proprietory colony, in 1641 and 1635. The Carolinas were granted to the Duke of Albemarle and others in 1662. The early colonists were sons of English Cavaliers, Puritans, Irish Presbyterians, Scotch Highlanders, and in S. Carolina many Huguenots. In the next year the New Nether-

lands were conquered by the English, who changed the name of the province to New York. New Jersey, which had already been thinly peopled by Swedish immigrants, was in 1665 and the following years settled by English Quakers, New England Puritans, and Scotch Presbyterians. Pennsylvania was founded in 1681 by William Penn, and was settled mainly by Quakers, Germans from the Palatinate, Huguenots, and Irish Presbyterians. Delaware, an offshoot of Pennsylvania, separated from the mother colony in 1703; and in 1733 Georgia was founded by General Oglethorpe as a refuge for English debtors, orphans, and friendless youths. Some Scotch Highlanders and followers of Whitfield were also among the early settlers. Sketches of the early history of all these colonies will be found in the separate articles devoted to them.

Thus from the very beginning the U. S. were peopled by immigrants of the most widely different races and creeds. Every shade of the opinions, religious and political, which in the 17th c. led Britain into civil war and revolution upon revolution, was represented in full force among the British-born settlers. Almost every other European nation had also contributed its quota to the motley population, and it is said that in the New Netherlands alone, before the English Conquest, eighteen different languages were spoken. The history of each colony, almost from its formation, resolves itself into a record of Indian wars, minor disputes with the other colonies, and, above all, disputes with the authorities in England as to constitution, government, and taxation. In every colony a form of government, more or less resembling that of England in miniature, had either been established of set purpose, or had gradually grown up; yet there were great differences in the spirit with which the different populations regarded their internal institutions, and their relations to the mother country. In the southern colonies the Church of England was established, and the mass of the people belonged to it, while aristocratic and monarchical sentiments, fostered by influences of birth, location, climate, and possibly slavery, co-existed with a strong practical attachment to political freedom. In the northern colonies, independency was the rule in religion, autonomy in politics. The struggles between Massachusetts and the mother country on the subject of the appointment of governors, their salaries, and the afterwards so fatal question of the right of taxation, had been fierce and rancorous, and had even threatened to lead to open rebellion, while the more southern settlements had invariably maintained an attitude of loyalty, whatever firmness they may have shown in claiming and maintaining what they believed to be their rights. From the time of James I. downwards, the policy of the home government had been one of interference and attempted oppression. The navigation laws and the prohibition of manufactures in America were of comparatively small moment, as the former were systematically evaded; and as for the latter, the colonists had neither desire nor opportunity to compete with the mother country in manufactures. The attempts to restrict the right of representation, and to secure for the Crown the nomination of colonial governors, were more serious grievances. In the majority of the colonies the Crown actually succeeded in obtaining this right, and sent out men of low character and small ability, who made themselves and the home government unpopular in the colonies, and brought the colonies into disrepute at home by their unjust and prejudicial reports, from which the English authorities gained almost their whole knowledge of American affairs. The claim of the home government to tax the colonies, though it was among the earliest subjects of dispute, remained an entirely subordinate point of difference, until the wealth of the American possessions had increased so much as to excite the cupidity of English statesmen, when it suddenly assumed the front place among the causes of discord, and resulted in the Revolution and the Declaration of Independence.

Two hostile foreign nations held positions on the frontiers of the colonies. Florida was under Spanish rule, Louisiana and Canada were in the hands of France. Between 1736 and 1742 the colonists of Georgia and S. Carolina were engaged in several petty wars with the Spaniards. A few years later the French formed a design of connecting Canada and Louisiana by a chain of forts along the Ohio and the Mississippi, thus closing in the western frontier of the colonies. During the ten years between 1753 and 1763 a desultory war was carried on, the chief events of which were Braddock's defeat at the Monongahela in 1755, and Wolfe's capture of Quebec in 1759. In this war the colonies had borne more than their share both of danger and expense, and had actually gone considerably into debt; yet scarcely was it concluded when the British Government began to hatch schemes for eking out the imperial revenue by imposts upon the already impoverished dependencies. With Grenville and Townshend rests the responsibility of originating this suicidal policy, with George III. that of supporting and confirming them in their unconstitutional course. It is impossible here to follow the details of the quarrel. Grenville gave notice of the Stamp Act in March 1764; it was passed a year later, and repealed a year later again, the concession being at the same time nullified by an Act asserting explicitly the general right of Parliament to tax the colonies. The Act imposing duties on tea and other imports was passed in May 1767, and was met by a resolution on the part of the colonists to abstain from the use of such imported articles. In 1770 all the duties were remitted except that on tea, which brought into the Treasury the sum of £300 per annum. Concessions in detail, however, had by this time lost their power of throwing dust in the eyes of the Americans; they saw that they were, in effect, mere re-assertions of the unjust and unconstitutional principle. *Non agitur de vectigalibus, libertas in dubio est* was now their belief; and in December 16, 1773, the cargoes of three tea-ships were emptied into Boston harbour. In punishment of this and other acts of insubordination, an Act was passed closing the port of Boston, and inflicting other pains and penalties on the rebellious citizens. The remaining colonies rose like one man to express in word and deed their sympathy with Massachusetts. An inter-colonial congress met at Philadelphia, September 5, 1774, arming and drilling of provincial levies was actively carried on, and it became clear that there was no prospect of obtaining the submission of the colonies without an appeal to force. To us the condition of the popular mind of England, as represented by its servile Parliament and its short-sighted ministers, seems almost incredible. Townshend spoke of the colonists as 'these American children, planted by our care, nourished by our indulgence, and protected by our arms.' In vain Barré replied in the House of Commons:—'They planted by *your* care! No; your oppressions planted them in America. They nourished by *your* indulgence! They grew up by your neglect of them. They protected by *your* arms! They have nobly taken up arms in your defence.' Conway and Shelburne, Burke and Chatham, asserted in vain the impolicy and injustice of the Government's course. They persisted in it blindly, and made of a handful of disunited dependencies a great and united independent empire.

The first blow was struck at Lexington and Concord Bridge on the 19th of April 1775, when it is said that the British troops on their retreat to Boston lost over 300 men. This was followed by the blockade of the troops in Boston and the battle of Bunker Hill (June 17th), in which the British gained a victory, though with a loss nearly double that of the Americans. As early as May the Congress, sitting at Philadelphia, had appointed George Washington, who had already distinguished himself both by courage and conduct in the French war, commander-in-chief of the Continental forces. Ticonderoga and Crown Point, important posts between New England and Canada, were taken by the Americans, but an attack upon Quebec by Montgomery and Arnold in the winter of 1775-76 failed completely. In Virginia the British Governor, Lord Dunmore, emancipated the slaves and armed them against their masters, but effected little beyond the destruction of Norfolk, the richest town in the colony. It had by this time become evident to the British Government that the colonists were no despicable opponents. Foreign mercenaries were enlisted to crush them, Indian tribes were armed against them, and means were resorted to which would have brought discredit upon the British cause, even had it been in itself just. Still through the winter of 1775-76 the colonies hesitated formally to throw off their allegiance to Britain. In the spring of 1776, however, the Navigation Laws were formally repudiated by the Congress opening the ports of America to all nations. One after another the colonies declared themselves independent States, and the united Declaration of Independence of the thirteen colonies, drawn up by Adams, Franklin, Jefferson, and two others, was signed on the 4th of July 1776. 'We must all hang together,' said Franklin, 'unless we would all hang separately.'

On the 16th of March 1776 the British evacuated Boston, and Washington took possession of it; but the following July, a force

sent out under Lord Howe defeated the Americans under Putnam at Brooklyn, took New York, and forced Washington to retire on Philadelphia. New Jersey and Pennsylvania now became the main scene of operations. In engagement after engagement Washington was defeated, almost the only exception being the brilliant skirmish of Trenton, December 26, 1776. On September 11, 1777, Washington was defeated at Brandywine (q. v.), a fortnight later Lord Cornwallis (q. v.) occupied Philadelphia, and on October 4 the Americans suffered another defeat at Germantown (q. v.). The British, however, found it easier to conquer than to subdue. Victory on victory did nothing to advance their cause, and the Continental levies were gradually becoming more and more skilled in the art of war. Foreign officers, of whom Lafayette (q. v.) and Steuben (q. v.) were the most notable, were disciplining and training them, and they were earning the respect of foreign Powers by their dogged resistance. Moreover, their hopes were kept up by successes in other quarters. A British attack on S. Carolina in the spring of 1777 was entirely defeated, and General Burgoyne (q. v.), attempting to march from Canada down the Hudson to join Clinton in New York, was forced to surrender with his whole force at Saratoga (q. v.), October 16, 1777. Early in the next year an alliance was concluded with France; and though a second British attack on S. Carolina was more successful than the first, the apparent advantage was counterbalanced by the evacuation of Philadelphia. During 1778 the British successes in the South continued, but were barren of result, and the treachery of Benedict Arnold was of no advantage to the British, while it led to the execution as a spy of the gallant André (q. v.). The next year (1781) saw the final blow to the British power in America. Cornwallis, attempting to join Clinton in New York from the South, as Burgoyne had attempted from the North, was surrounded at Yorktown (q. v.), and forced to surrender with his whole army on October 19. This virtually ended the war, though peace was not signed till September 3, 1783, and the British troops did not evacuate New York until November 25 of the same year.

Their independence established and recognised, the next care of the States was to provide themselves with a Constitution and a settled form of government. A Convention assembled at Philadelphia in 1787 for this purpose, and drew up the Constitution which has been sketched above. The great difficulty was to adjust the balance of power between the Central Government and the Governments of the various States; and the Constitution as it stands is the result of a compromise between the two parties which had already developed themselves in American politics. (See REPUBLICAN.) Hamilton (q. v.) and Madison (q. v.) were the leaders on the Federal side, and Jefferson (q. v.) and Patrick Henry (q. v.), who, however, were not members of the Convention, on the side of the Democrats. In 1789 Washington became the first President of the U. S., and held the office during two terms. Vermont was admitted as a State in 1791, Kentucky in 1792, Tennessee in 1796, the last year of Washington's Presidency, and Ohio in 1802. John Adams (q. v.) succeeded Washington as President in 1797, and Thomas Jefferson held the Presidency for two terms (1801–1809). Madison who succeeded him (1809–17) had by this time gone over to the party of the Democrats, who sided with France and opposed Great Britain in the European struggle then at its height. A dispute as to the right of British commanders to search American vessels for deserters led to a war with Britain which lasted from 1812 to 1815, and was principally notable for its stirring sea-fights, the capture of Washington and Baltimore by the British (1814), and the defence of New Orleans (1814–15), in which General Andrew Jackson (q. v.) first came prominently to the front. An enormous acquisition of territory had been made in 1803 by the purchase from France of the province of Louisiana, then held to include an indefinite stretch of country W. of the Mississippi. In 1812 the State of Louisiana was admitted to the Union, and was followed by Indiana (1816), Mississippi (1817), Illinois (1818), Alabama (1819), Maine (1820), and Missouri (1821). In 1820 Spain ceded Florida to the U.S. Madison was succeeded in 1817 by James Monroe (q. v.), now principally remembered by his famous 'doctrine' of 'America for the Americans,' who, after two terms, gave place to John Quincy Adams (q. v.) in 1825. The fiftieth anniversary of independence was celebrated on the 4th July 1826, on which day, by a strange and striking coincidence, Thomas Jefferson and John Adams, authors of the Declaration of Independence, both died. The next Presidents were Andrew Jackson (1829–37), Martin Van Buren (1837–41), W. H. Harrison, who died after holding office barely a month, and was succeeded by the Vice-President John Tyler (1841–45), James Polk (1845–49), and Zachary Taylor, who died after fifteen months of office, and was succeeded by Vice-President Millard Fillmore (1849–53). During Jackson's presidency the chief political question was that of free-trade against protection. The South supported free-trade, the North protection, and on the passing of a high protective tariff, S. Carolina, a State always inclined to insubordination, threatened to take refuge in 'Nullification,' or the alleged right of a State to repudiate the measures of the central government. The dispute was settled by a compromise brought about by the new 'Whig' party, at whose head were Henry Clay (q. v.) and Daniel Webster (q. v.). Tyler's presidency was marked by serious difficulties with Great Britain, which were, however, peaceably concluded by the Ashburton treaty, which settled definitely the boundaries of the British possessions.

From an early period it had been apparent that slavery must be the test question in the political differences between the North and South. The climate and form of agriculture in the South were favourable to slave labour, while in the North they were unfavourable. By a natural reaction, slavery affected the habits and modes of life and thought of the white population of the South. Their prejudices and their interests alike differed from those of the Northerners. Not that there was at first any such passionate attachment to the principle of slavery as was afterwards fostered by circumstances; on the contrary, such men as Washington and Jefferson, themselves slave-owners, looked forward to the gradual abolition of a system whose evils they recognised, and their views were very widely shared in the South. In 1808 the importation of slaves was made illegal; so late as 1832 the Virginian Assembly discussed the question of abolishing slavery in the State; and, in fact, it was very generally held to be an evil, necessary for the present, but which should be allowed to die out as soon as possible. On the other hand, the Northern opposition to slavery was not organised till 1833, and cast no votes till 1840. As the territory of the U. S. extended, however, and as new States were admitted to the Union, the question became one of overwhelming political importance. If slavery were permitted in the new States, they would naturally throw in their lot with the South; if not, they would side with the North. As a large proportion of the new States and territories were fitted by nature for slave labour, the South demanded that the question of its permission should be left to the State itself, and thus the old question of State rights as opposed to central authority became doubly important. On the admission of Missouri in 1821 an arrangement was arrived at—known as the 'Missouri Compromise'—by which it was provided that slavery should be prohibited N. of 36° 30′ N. latitude, and permitted S. of that line. Arkansas and Florida, admitted in 1836 and 1845 respectively, were S. of this line; Michigan, admitted in 1837, was N. of it. In 1837 Texas, which had recently thrown off the Mexican yoke, claimed admission to the Union. A long struggle followed. The North, unwilling to incur a war with Mexico, and equally unwilling to add to the number and power of the slave States, opposed the claim, while the South favoured it. The latter ultimately carried the day. In 1846 Texas was admitted to the Union; and in 1847 General Taylor defeated Santa Anna at Buena Vista, and General Scott, landing at Vera Cruz with 12,000 men, invaded the heart of the Republic and took the city of Mexico. Iowa and Wisconsin were admitted as States in 1846 and 1848 respectively. By the Treaty of Guadalupe, Hidalgo (2d Feb. 1848), New Mexico, and California became territories of the U. S.; and the great Californian gold discoveries following almost immediately, a vast rush of emigration ensued, so that by 1850 California was ready for admission to the Union. California had in 1849 adopted a constitution prohibiting slavery, and the South was loud in its demands not only for the rejection of California, but for an amendment to the Constitution against the further proscription of slavery. The fierce struggle which ensued was terminated by Henry Clay's Compromise Act, which admitted California as a free State, and prohibited the slave-trade in the Federal District, but made large concessions to Texas, and enacted a law for the rendition of fugitive slaves. This settlement only increased the public agitation. Franklin Pierce was elected President in 1852 by the South and the

Northern Democracy, and in 1854 Stephen A. Douglas of Illinois proposed the 'Kansas and Nebraska Bill,' in which he announced his doctrine of 'Squatter Sovereignty,' leaving to the territorial inhabitants to decide by vote whether they would have slavery or not, and repealing the 'Missouri Compromise.' This bill was passed, and a great struggle ensued between the North and South as to the introduction of slavery into Kansas. After much bloodshed and anarchy it was admitted as a free State in 1861. In 1857 Pierce was succeeded by James Buchanan; Oregon and Minnesota were admitted as States; and a decision in the Supreme Court laid down as law that negroes though free could not be citizens of the Union, that Congress had no power to forbid slavery in any State or territory, and that slaves, if bought in a slave State, could be removed to a free State, and still remain slaves. This decision, known as the Dred Scott decision, strengthened the desire of the North for radical reform in the constitution with regard to slavery, and matters came rapidly to a crisis. In 1859, John Brown, a New York Abolitionist, who had attempted, against the Fugitive Slave law, to run off slaves from Virginia, was captured, tried, and hanged by order of a Virginian court at Harper's Ferry, Virginia, and immediately was regarded as an anti-slavery martyr. The next presidential election (November 1860) was a test-struggle, and when, owing to the division of parties, four candidates were in the field, and Abraham Lincoln (q. v.), Republican, was elected, South Carolina seceded from the Union in December 1860.

President Buchanan, who served for four months after Mr. Lincoln's election was known, might possibly have arrested the Secession movement had he acted promptly and vigorously, but he lacked nerve in the great emergency, and the disruption went on. In February 1861 a Confederacy was formed, consisting of South Carolina, Georgia, Alabama, Mississippi, Louisiana, Texas, and Florida. Jefferson Davis (q. v.) was chosen President, and Alexander H. Stephens (q. v.) Vice-President. Virginia, North Carolina, Tennessee, and Arkansas soon joined the Confederacy, and active preparations for war were made on both sides. We cannot here attempt to follow in detail the operations of a war which raged for four years, and spread over an enormous extent of territory. From the first the policy of the South was mainly defensive, the inroads made by its troops into Northern territory being, with few exceptions, only feints. The object of the North, on the other hand, being to bring back the seceding States to obedience to the Constitution and fealty to the Union, the Federals naturally became the invading and aggressive party. The main points, or rather lines of attack, were two. The Federal and Confederate capitals, Washington and Richmond, looked each other in the face at a comparatively short distance, and thus the valley of the Potomac and Northern Virginia became one great battle-ground. Here Lee (q. v.), perhaps the most astute general the war produced, was pitted against M'Clellan, Pope, Burnside, Hooker, Meade, and ultimately Grant, fighting with varied fortune, but with a courage, skill, and determination, under the most adverse circumstances, which cannot be sufficiently admired. Though seconded early in the war by that remarkable strategist, 'Stonewall' Jackson (q. v.), and after his death by Ewell, Stuart, and Longstreet, Lee himself deserves the principal credit of the series of campaigns in which for three years forces overwhelmingly superior to his in numbers, arms, and supplies were completely held in check. The Mississippi formed the other line of attack. Down its course Halleck, Grant (q. v.), Sherman (q. v.), Rosecrans, and Thomas, fought their way, sometimes checked (for Johnson, the Confederate commander, was an able general), but generally victorious, and pressing steadily on, aided by the naval forces which blockaded the ports and destroyed the Confederate war-steamers and iron-clads, at last had the Southern and South-Western States entirely at their mercy. The North had the advantage from the first in men, money, and supplies, and in the fact that southern territory was the battle-ground. These circumstances had their weight, but the Federal generals and armies were not lacking in military skill, courage, or persistency, and the result would probably not have been different had the parties been more equally matched. The proclamation of emancipation issued by President Lincoln, January 1, 1863, aided the Federal cause; and when, a year later, General Grant was appointed lieutenant-general and commander-in-chief, measures were adopted which, with vast expenditure of money and life, brought the war to a close. The two armies East and West acted in harmony; Grant directed the operations on the Potomac and James in person, and Sherman made a brilliant succession of marches, from Chattanooga to Atlanta, from Atlanta to the sea at Savannah, and thence northward to N. Carolina to join Grant. Richmond fell April 3, 1865, General Lee surrendered April 9, and the war was practically ended, April 14, 1865. President Lincoln, who had just entered upon his second term, was assassinated, and the whole nation was in mourning. The Vice-President, Andrew Johnson, succeeded him, and soon came into collision with Congress in regard to the reconstruction of the seceded States, and his impeachment was attempted, but unsuccessfully. The Presidential election of 1868 resulted in a Republican victory, Seymour the Democratic candidate being defeated by General Grant, who held office for two terms, and was succeeded in 1877 by Rutherford B. Hayes, also a Republican. Four new States have been admitted since the outbreak of the war—West Virginia (1863), Nevada and Nebraska (1864), and Colorado (1876). In 1869 the Pacific railroad from Omaha on the Missouri to San Francisco was completed; other transcontinental roads are now in progress. The claims made by the U. S. Government for damages done during the war by the *Alabama* and other Confederate cruisers built and equipped in British dockyards, at one time threatened to lead to war between the two nations, but were peacefully settled by the Geneva arbitration (1872), which awarded to the U. S. a gross sum of $15,500,000. There have been several small Indian wars of late years in Arizona, Montana, and elsewhere, and the U. S. have suffered one terrible disaster in the total annihilation of five companies of cavalry commanded by General Custer, in an attack upon a tribe of Sioux under the leadership of 'Sitting Bull' (1876). A great International Exhibition at Philadelphia celebrated the centenary of American Independence in 1876. There were strikes, and in a few instances riots, among railway employés on the Great Trunk Railway in August 1877, but these were soon suppressed, and the worthless 'tramps,' who were the principal rioters, arrested and punished. Socialism and communism were feared from the large immigration of European Communists in 1877 and 1878; but a free country is the last place where anarchists can make any headway, and all their efforts have proved abortive. In 1878 an International Commission gave an award of £1,100,000 against the U.S. on account of the losses from the fisheries in the maritime provinces of the Dominion of Canada. The history of the U.S. during the next twenty years cannot fail to be as interesting, though it may not be so painfully exciting, as that of the past two decades. See Bancroft's *History of the U. S.* (new ed. 6 vols. Lond. 1876), Doyle's *American Colonies Previous to the Declaration of Independence* (Lond. 1869), and the same author's *History of America* (Lond. 1874), Cassell's *History of the U. S.* by E. Ollier (Lond. 1874–77), W. Cullen Bryant and S. H. Gay's *Popular History of the U. S.* (New York, vols. i. and ii. 1876–79).

Literature.—A great deal of ingenuity has been expended in explaining why the U. S. do not and can not excel in literature and art as they excel in invention and industry. The inquiry is a somewhat futile one, since, so far as literature at least is concerned, the fact sought to be explained does not exist. The U. S. have during the present century contributed more than their fair share to the literature of the English language. Nor is it the case, as is often alleged, that their best writers never get beyond the more or less successful imitation of European models. Their literature is now original and national in the highest and best sense. So early as 1638, Harvard College was founded at Cambridge, Massachusetts. In Virginia, where up to the Revolution there had been, as one of the governors had boasted, neither a school nor a printing-press, William-and-Mary College was founded in 1690. Yale College, in Connecticut, was founded in 1701, and three years later the first American newspaper, the *Boston News Letter*, was started. During the 17th c. there were several now forgotten theological writers among the New England Puritans. Increase and Cotton Mather (q. v.) are, however, still remembered, the latter with a notoriety not altogether literary. William Bradford (1588–1657), the second Governor of Plymouth, wrote a history of that colony and an account of New England in verse; and Anne Bradstreet (1612–72), wife of a Governor of Massachusetts, published a volume of poems in 1640 which were reprinted in London, 1650, under the title of *The Tenth Muse*

lately sprung up in America. William Hubbard (1621-1704) wrote a history of the Indian wars in New England, as well as a general history of the colony. The greatest of pre-revolutionary writers was undoubtedly Jonathan Edwards (q. v.). Contemporary with him was William Stith (1689-1755), who wrote a history of Virginia, which unfortunately did not extend beyond the earliest period of the colony. Logan (1674-1751), Rittenhouse (1732-96), and Godfrey distinguished themselves in natural science, and Bertram (1699-1777) was a botanist of eminence. The awakening of national life at the Revolution was naturally accompanied by a revival of letters. Madison (q. v.) and Hamilton (q. v.), by their essays under the title of *The Federalist*, greatly advanced the cause of the Constitution, and in political history the writings of Jefferson (q. v.), Patrick Henry (q. v.), and the Adamses (q. v.) will always be of value. Both in politics and science Franklin (q. v.) takes a leading place. Poetry of more or less merit was written by Dwight (q. v.), Barlow (q. v.), Trumbull (1750-1831), Hopkinson (1738-1791), Humphreys (1753-1818), Mrs. Warren (1728-1815), and Brackenridge (1748-1816), who wrote a drama on the Battle of Bunker Hill. *Yankee Doodle* was written by a certain Dr. Sheckburg about the middle of the 18th c., and *Hail Columbia* by Francis Hopkinson in 1798. After the Revolution came a period of imitation of English models, in which Irving (q. v.) and Cooper (q. v.), justly called the American Goldsmith and Scott, are the leading figures. C. B. Brown (q. v.), Washington Allston (q. v.), R. H. Dana (d. February 1879), Fitzgreene Halleck (q. v.), John Pierpont (1785-1866), James Kirke Paulding (1799-1860), John Pendleton Kennedy (1795-1870), James Hall (1793-1868), Charles Sprague (b. 1791), and James Gates Percival (1795-1856), also deserve mention among the imaginative writers of this period. The next generation was, or rather is, of different and stronger stuff. Foremost among them in point of time as well as in literary significance stands Ralph Waldo Emerson (q. v.), one of the most original thinkers of our century, cosmopolitan in a sense, yet at heart intensely American. Equally original, though in a different fashion, was the genius of Nathaniel Hawthorne (q. v.), whose subtle and sombre imagination is unique in the history of literature. Edgar Allan Poe (q. v.) was a poet and essayist whose excellences have only of late been fully appreciated. William Cullen Bryant (q. v.), as poet, essayist, and publicist, occupies a high rank, blending classic dignity with a deep sympathy for American life and scenery, while Henry Wadsworth Longfellow (q. v.), the most popular of American poets, has drawn much of his inspiration from the history, characteristics, and scenery of the New World, though his cultured fancy finds an equal charm in the distant splendours of medieval Europe. James Russell Lowell (q. v.), wittiest of critics and poets, first attracted attention by a humorous dialect poem on certain phases of American politics. John Greenleaf Whittier (q. v.) is characterised by earnest enthusiasm, intense sympathy for humanity, and ardent love of nature; while Oliver Wendell Holmes (q. v.), who, in poetry, is the most graceful writer of *vers de société* in America, unites in his prose works deep scientific and literary insight with the most genial and charming humour. Among other imaginative writers and critics the following deserve mention:—N. P. Willis (1807-67), C. P. Cranch (b. 1813), Bayard Taylor (q. v.), J. G. Holland (b. 1819), R. H. Stoddard (b. 1825), Richard Grant White (b. 1822), E. P. Whipple (b. 1819), J. T. Fields (b. 1817), and among the younger generation E. C. Stedman (b. 1833), T. B. Aldrich (b. 1836), W. D. Howells (b. 1837), and Henry James, jr., Hjalmar H. Böjesen, and Joaquin Miller (b. 1841), whose rank among poets is still undetermined, but whose verse is redolent of the Far West, and who seems ambitious to be regarded as the 'Byron of the prairies.' Walt Whitman (q. v.)., 'the poet of democracy,' is a literary phenomenon, not as yet appreciated except by a select few of the initiated on both sides of the Atlantic. H. D. Thoreau (q. v.) will probably be remembered rather as the friend of Emerson than as what he was—a curious combination of the poet and the naturalist. Another friend of Emerson, William Ellery Channing (q. v.), heads the list of American theologians, which can also show such names as that of Charles Hodge (1797-1878), Mark Hopkins (b. 1802), Gardiner Spring (1785-1873), Wm. Staughton (1770-1829), and Alex. Campbell (1786-1866). Of popular preachers the most notable are H. W. Beecher (q. v.), R. S. Stons (b. 1821), R. D. Hitchcock (b. 1817), and T. de Witt Talmage (b. 1832). R. D. Owen (q. v.) deserves mention for his writings on social philosophy. Mrs. Harriet Beecher Stowe (see BEECHER), author of *Uncle Tom's Cabin*, &c., Mrs. Hale, Mrs. Osgood, Mrs. Sigourney (q. v.), Miss Sedgwick, Mrs. C. M. Childs, Mrs. Parton ('Fanny Fern,' 1811-72), C. E. Beecher (1800-1878), Mrs. Terhune ('Marion Harland,' b. 1835), E. Stuart Phelps (1815-52), Susan and Anna Warner (1818 and 1820), Mrs. A. D. Whitney (b. 1824), M. A. Dodge ('Gail Hamilton'), Louisa M. Alcott, Mrs. F. H. Burnett, &c., are among the most noted authoresses. American historians are not inferior to American poets. Washington Irving did some graceful if not profound historical work; George Bancroft (q. v.) has made the history of his own country his study, William Hickling Prescott (q. v.) devoted himself to Spain and the Spanish conquests, and John Lothrop Motley (q. v.) to Holland and Germany, while George Ticknor (q. v.) gave us the best history of Spanish literature in any language. The last four of these, by their talent and original research, take a place in the first rank of historical authors. Noah Webster (q. v.) and Joseph Emerson Worcester (1784-1865) are among the best known of English lexicographers, and W. D. Whitney (b. 1827) is known throughout Europe as one of the most distinguished of philologists. We now come to the latest and perhaps the most characteristic development of American literature, commonly known as 'American humour.' The germ of the peculiar humoristic manner, which distinguishes American comic writers, is to be found in several American classics. It appears in Irving, it is very prominent in Lowell and Holmes, and is even traceable in Emerson. Charles F. Browne (q. v.), or 'Artemus Ward,' was the first of the humorists properly so called. He set the fashion of misspelling, which has done a great deal to hide the true merits of American humour, but he was in his way a writer of genuine comic invention and originality. By far the greatest of the humorists, however, are Francis Bret Harte (q. v.) and Samuel L. Clemmens or 'Mark Twain.' The former possesses much real (as well as much unreal) pathos, along with brilliant wit and keen power of observation, and is a true 'humorist' in the sense in which Thackeray used the term. The latter, with an unrivalled fertility of comic invention, possesses a power of graphic description which raises him far above the mass of comic writers. Charles G. Leland (q. v.) is distinguished by genuine scholarship along with humorous power; Henry W. Shaw, or 'Josh Billings' (b. 1818), conceals trenchant wit and keen observation beneath a foolish mask of affected bad spelling. R. H. Newell, or 'Orpheus C. Kerr' (b. 1836), Seba Smith, or 'Major Jack Downing' (1792-1868), Max Adeler, J. P. Bailey, or 'the Danbury Newsman,' 'Dod Grile,' and John Habberton, also deserve mention. American humorists suffer in the estimation of the English cultured public, partly by reason of a certain superficial vulgarity which they almost all share, and partly on account of the cheap and catch-penny form in which their works are issued by English publishers. See M. C. Tyler, *History of American Literature*, 1607-1765 (2 vols. Lond. 1879), and Duyckinck's *Cyclopædia of American Literature* (2 vols. new ed. Philad. 1878).

Uni'ted States of Colom'bia. See COLOMBIA, UNITED STATES OF.

U'nities. The law of the *Three U.* of *Place*, *Time*, and *Action*, which ruled supreme in the classical period of the French drama, demanded that there should be no shifting of the scene from place to place, that the whole series of events should be such as might occur within the space of a single day, and that nothing should be admitted irrelevant to the development of the single plot. The introduction of the law was due to Richelieu, who, being pleased by Mairet's *Sophonisbe*, in which the U. were observed, secured their formal enactment by the Abbé d'Aubignac in his *Pratique du Théâtre*. The restrictions were accepted by Corneille, Racine, and Voltaire, and in short continued in force till the rise of the Romantic school; though Corneille himself, in his essay on the subject, admitted that the unity of place at least had no support from Aristotle or Horace, whose authority had been claimed by D'Aubignac. For a time the validity and value of the law were matters of keen debate.

U'nivalves, the name applied to those shells which consist of a single piece. Thus the shell of a snail, whelk, or corory is a univalve. The term is used in opposition to *bivalve*, applied to the oysters, cockles, clams, and other *Lamellibranchiate*

(q. v.) shells, and also to *multivalve*, in which more than two pieces are developed.

Univer'salists are those who believe in the ultimate salvation of all men and created spirits; negatively they direct their criticism against an eternal hell, in some cases even against any suffering after death. Their arguments may be thus briefly summed up :—1. The word (*aionios*) translated 'everlasting' or 'eternal' properly describes the 'age' or 'duration' of the noun to which it is attached, and derives its extension of meaning from the noun. Thus 'eternal' life may be everlasting, because it is in and from God, but 'eternal' death is not necessarily everlasting, because the *æon* ('cycle of duration') of the latter is not necessarily co-extensive in duration with the *æon* of the former. 2. The general character and teaching of Christ is inconsistent with the doctrine of eternal punishment. 3. The view is also inconsistent with a just conception of Deity, as it either (*a*) limits his power to save, or (*b*) denies his desire. 4. It is impossible for the most wicked man to do anything during his life sufficient to deserve so awful a retribution; besides, if the opposite view be taken in its extreme character (as represented with the startling abruptness of documents like the Confession of Faith), only a very small portion of the human race are saved. All the rest, however good they may be humanly speaking, are condemned to unspeakable and unceasing anguish. But this is to confess the failure of and really to caricature Christianity. To these arguments it has been replied—1. Generally, the arguments for eternal punishment must not be discredited because the case has been put in a false light by certain advocates of this doctrine. Few would now maintain that the future punishment of the wicked is physical, or would extend the limits of the 'wicked' so widely as to include Socrates and Plato. 2. We are obliged to infer some form of eternal retribution; (*a*) from a loyal adherence to the words of Scripture, which, on a fair and natural construction, seem really to teach this doctrine; (*b*) from a general conviction of the wickedness of sin and the necessary infinite consequences of a transgression, which, though committed in time, has yet endless results. Moreover, there is nothing unreasonable or unjust in the conception of this world as a period of probation, and this is what the orthodox view really asserts. Origen (185–283) may be taken as the founder of the theory of Universalism. He held 'that the resurrection nature of mankind will not include material bodies; that the punishment of the wicked and of evil spirits will not be eternal, and that all intelligent beings tend towards re-absorption into the One fountain of Being from which they sprang.' Origen is, however, only one of many great Patristic names that could be quoted in support of the doctrine, though previous to the Reformation it never acquired much force, as the indefinite limits of purgatory softened the extreme harshness of the two opposing alternatives. In post-Reformation times there were again many individuals who leaned towards this belief, but the extreme harshness of the theological disputations of the period prevented the growth or even the existence of the doctrine as that of a sect. About 1750, James Kelly, a Unitarian clergyman, founded the English sect of U., which up to the present day has maintained a languishing existence. John Murray, once an English Methodist, emigrated to America about 1770, and established the doctrine of the U. there. The sect grew and prospered, and had in 1862 1000 congregations, 8 academies, and 3 colleges. It would not be just, however, to hold an enumeration like that just given a fair measure of the influence of the U. Their distinctive doctrine is openly held in some form or other by an increasing number of members of all the churches. A belief in Universalism is no bar to office in the Church of England—perhaps not even in the Scottish Church. Like many other heresies, its influence is not to be measured by the number of its professed adherents, but by its general influence on the whole Christian Church. See Whittimore's *History of Universalism* (Boston 1860); Williamson's *Exposition and Defence of Universalism* (New York 1840). *Cf.* also G. Macdonald's eloquent *Unspoken Sermons* (Lond. 1866), and the work kindred in thought, Canon Farrar's *Eternal Hope* (*ib.* 1878).

Univer'sities, though offering analogies to Greek and Roman schools, trace their historic continuity no further than the 12th, or, at the most, 8th c. A.D. Their germs must be sought in the Karoling schools of France, the Palatine, and Italy, and the Saracen schools of Bagdad and Cordova, in such distinctively professional institutes as Salerno's of medicine, Bologna's of Roman law, and in the Paris lecture-rooms of the early schoolmen, Abelard, Roscelin, and William of Champeaux. One science attracts another, and so fresh faculties were added to arts, to medicine, or to law; teaching begets instructors, and these received their stamp of fitness in Degrees (q. v.). Through gradual development from within, aided by charters of kings and popes from without, schools grew into U.,—corporations, that is, of teachers and scholars (*universitates doctorum et scholarium*), though later interpreted 'places of universal study' (*studii universitates*). Such growth has been fully traced in two typical cases, PARIS and OXFORD; each seat of learning has been specially described; so here need be only handled the spread, the general aim, and present state of U. Their type, first struck at Bologna (*cir.* 1158), Paris (1200), Oxford (12th c.), and Cambridge (1229), was reproduced by members of foreign 'Nations' returning home, as when in 1348 the Paris student Karl IV. founded at Prague the earliest university within his empire; or by emigrant students, as when in 1638 the colonists of Cambridge, Massachusetts, erected Harvard on the lines of the Old-World Cambridge. Again, St. Andrews (1413) owed its establishment to wars that cut off the studious Scottish youth from their Moray College at Paris, and the Reformation, opening religious, as wars political, breaches, called into existence new Protestant U. Theoretically at least, the aim of every university is the same—instruction of youth in liberal culture, primarily to develop school-gained knowledge into science, secondarily to promote its practical application. As knowledge widens, teachers themselves must follow up new paths of study, where English Fellowships (q. v.) were meant for their *viaticum*; for as careers are always multiplying, the students' claims on the professors multiply. A perfect university were that at which teachers could teach and all learners who would could learn everything. An impossible ideal this, but let us see how near the various U. approach, how far fall short of it. No country has so many and so well-attended U. as Germany, as shown by the following table for 1878, where the date of foundation is given and the division into the four faculties, of which philosophy embraces the humanities, mathematics, and natural science :—

UNIVERSITIES.	INSTRUCTORS.	STUDENTS.				
		Theology.	Jurisprudence.	Philosophy.	Medicine.	Total.
Berlin (1810)	214	168	1158	1163	345	2834

Total	1887	2294	5097	6749	3706	17,846

The average annual expenses of the ten Prussian U. amount to £370,000, of which the State defrays about two-thirds; on Leipzig the Saxon Government bestowed £37,744 in 1877, internal revenues supplying the rest, £17,304. These are small sums compared with the result attained—the conferring, namely, of university training on 1 per 2400 of the entire German population. The possibility of the high standard of this education depends as elsewhere on the state of the schools, and from school every student must bring a *maturitätszeugniss*, answering to our B.A. degree. This falls outside the university sphere, as also does the *staatsprüfung*, or Government examination, which all candidates for the church, the bar, or medical profession have to pass; so that during his university career a student is left to cultivate knowledge for knowledge' sake. For *the* degree, of

doctor, he has to produce a thesis on some self-chosen subject of research—one reason this of Germany's grand advancement of science; the other being its system of *privat-docenten*, or assistants of the professorate, who, with the professional standard before their eyes, keep the professors themselves up to the mark. Non-residence, cheap living, and the *verbindungen* (student-brotherhoods), supplying partly the place of a college system, but unfortunately associated with foolish duels, are among the most striking features of German U., which, starting with strong Renaissance and Reformation impulses, stiffened awhile into torpid orthodoxy, but thence were roused by the Napoleonic wars. Austria has nine U.—Vienna (1365; with 246 instructors and 3975 students in 1878*), Prague (1348; 129 and 1592), Pesth (1777; 127 and 1979), Gratz (1827; 94 and 731), Innsbruck (1672; 66 and 600), Cracow (1401; 67 and 400), Lemberg (1817), Czernowitz (1875; 38 and 192), and Agram (1877). Vienna and Prague rank high as medical schools; all generally resemble the German U., but like the English they put great faith in multiplied examinations, a system an English scholar has likened to plucking up a plant by the roots to observe its growth. Also on the German model are the U. of Switzerland, Basel (1460), Zürich (1833), Bern (1834), and Geneva (1875), with an aggregate of 1149 students (among them some 90 women); of the Netherlands, Leyden (1575), Gröningen (1614), Utrecht (1636), and Amsterdam (1877), with 1800 students; of Belgium, Ghent (1816), Liège (1816), Louvain (1834), and Brussels (1837), with 2566 students; and of Scandinavia, Copenhagen (1479; 1200 students), Christiania (1813; 978 students in 1874), Upsala (1417), and Lund (1668), with 2080 students in 1871.

In Italy the seventeen State U.—Bologna (1158), Padua (1222), Pavia (1361), Turin (1404), &c.—in 1875 had 949 professors and 6553 students, not reckoning Naples (1224), where any native of the province may attend. Untouched by the Renaissance, these U., the latest stronghold of Averroism, have fallen from their high medieval estate, the students of to-day neglecting letters for such 'bread-studies' as law and medicine. Signor Bonghi's Act of 1875, assimilating them to the German system, was mainly rescinded in the following year, when the examining functions were restored to the various faculties. France is at present in a transition state. To replace the U. of Paris and twenty-two other towns, which the Revolution had swept away, a system of higher instruction was founded in 1808, by which every department has its academy and faculties, constituting, with a central examining and degree-granting body at Paris (resembling the London University), the University of France. In 1872 there were in all 421 instructors and 14,572 students in the five faculties of theology, law, medicine, mathematics and natural science, and literature (philosophy, history, and philology). This system has been materially modified by the clerical victory of 1875, by which corporations, associations, &c., are suffered to found free U., and whose fruits are the six new Catholic U. of Paris, Lille, Angers, Lyon, Poitiers, and Toulouse, with Jesuits (numbering 1461 in 1879) for instructors. The Government, unable to withdraw the consent once given, has since been occupied with a scheme for from five to six State U. established on the German pattern, but the plan remains hitherto on paper. Enough has been said under SPAIN and RUSSIA of their U., so we may pass to the English U. of Oxford and Cambridge, both independent corporations, free from the support and control of State, both immensely wealthy. Apart from university revenues, the Oxford colleges in 1874 had a yearly external income of £307,369, the Cambridge of £264,256. At the former university the professors numbered (1878) 48, the undergraduates 2659; at the latter there were 37 professors and 2485 undergraduates. Most of the Anglican clergy and many barristers study at the English U., but theology and law rarely form part of their studies; in 1877, 225 members of Parliament were university men, but only 250 of the 14,101 medical practitioners of England and Wales had graduated at Oxford, Cambridge, or Durham. Always to have held general culture as their main end, never to have degenerated into mere technical schools, are Oxford and Cambridge's proudest boasts; and Oxford, an Oxford professor testifies, 'has handed its traditional knowledge down, laid up in a napkin.' Both U. have lately recognised a sense of shortcomings in numberless reforms, such as the founding of twenty-four new chairs since 1847, the recognising by Cambridge of Local Lectures (1873), and the establishment of systems of Unattached Students (q. v.), while at Cambridge we find the Cavendish College (1876), 'designed for those who must commence the active work of life earlier than ordinary undergraduates,' and a proposed Selwyn Missionary College; at Oxford, Keble College (q. v.), a Military College, and a proposed Indian Institute. At present, however, the work of technical training is mainly thrown on such purely professional institutions as theological colleges, medical schools, and the Inns of Court; the University of London (q. v.) is merely an examining body, that of Durham (q. v.) only a miniature Oxford; and the surest hope of converting university training from an exclusive luxury into a national boon still lies in the proposed erection of Owens College (q. v.) and similar establishments into U., whose professorate might well be supplied by Oxford and Cambridge. The Scottish U., St. Andrews (1412), Glasgow (1454), Aberdeen (1506), and Edinburgh (1582), revert to the Continental type, the students being non-resident, their studies directly feeding the three learned professions, the teaching body consisting of professors and their assistants. Living is cheap, and the literary session falls in the five winter months, so that with the aid of Bursaries (q. v.) a lower social class enjoys the benefits of the U. than in any other European country. On the other hand, there is no entrance-examination, and the consequent mixture of forward and backward students renders a high standard of scholarship impossible, while by the Education Act of 1872 one of the best sources of trained material (the village 'dominie') has been swept away. In 1878 Aberdeen had 31 professors and assistants, and 625 students; St. Andrews 14, and 159; Glasgow 31, and 2018 (1243 arts, 60 divinity, 492 medicine, and 223 law); and Edinburgh, whose total income (1877) was only £26,783, 78 and 2545 (945 arts, 67 divinity, 1070 medicine, and 363 law). With these figures may be compared the 48 professors and 1110 students of the University of Dublin (q. v.) in 1879, with its revenues (1873) of £61,324; and the 52 professors and 886 students of the Queen's Colleges (q. v.), whose income (1878) was £33,504 (parliamentary grant £12,504). In 1875 there were no fewer than 545 degree-giving institutions within the United States (q. v.), but most of them, being inadequately endowed, furnish very secondary instruction; a very large proportion represent some sectarian opinion; and some 'have little more than a name, a charter, and a bias.' At the Revolution only nine colleges existed, Harvard (1638), William and Mary (1693), Yale (1701), &c.; to these before 1800 seventeen were added; the rest are of modern growth. Harvard and Yale, however, remain the only true U. in the European sense of the term, since they alone include theology, law, and medicine; the John Hopkins University, opened at Baltimore on the German plan in 1876, being not yet fully organised, and the scheme for establishing a national university at Washington being still (1879) a scheme. In 1876 Harvard had 128 instructors and 1263 students; Yale, 87 instructors, besides special lecturers, and 1021 students. See works cited under PARIS and OXFORD, and Stohr's *Deutsches Akademisches Jahrbuch* (vol. iv. Leip. 1879), whose issue for 1877 contains a full bibliography; also vol. i. of Raumer's *Geschichte der Pädagogik* (4th ed. Gütersl. 1872; Eng. trans. New York 1859), Zarncke's *Deutsche Universitäten im Mittelalter* (Leip. 1857), Sybel's *Deutsche Universitäten* (2d ed. Bonn 1874), Meyer's *Deutsche Universitatsentwickelung* (Berl. 1875), Budinszky's *Universität Paris im Mittelalter* (Berl. 1876), Cardinal Newman's *Historical Sketches of U.* (Lond. 1872) and *Idea of a University* (3d ed. Lond. 1873), and Brock's *American U.* (Cinc. 1875).

* All succeeding statistics, unless it be otherwise specified, refer to 1878.

Univer'sities Tests Act (1871) provides that no one shall be required on taking any degree, except a degree in divinity, from the universities of Oxford, Cambridge, or Durham, to subscribe any article or formulary of faith, or to conform to any religious observance or form of public worship; and the privileges of graduates are to be exercised also independently of doctrinal tests; but no office of the Church of England is open by this Act to any one who is not a member of the Church of England.

Univer'sity Coll'ege, Ox'ford, according to the now generally abandoned tradition, was founded by King Ælfred in 872, but its historic existence dates from the bequest (1249) of William of Durham, rector of Wearmouth, for the maintenance of certain 'masters.' The present foundation consists of a master, twelve fellows (one of them in Civil Law), and eighteen

scholars. The latter receive £80 for five years, and there are further about six exhibitions tenable for eighteen terms. U. C. presents to ten livings, and in 1878 had 113 undergraduates, 235 members of Convocation, and 446 members on the books.

Univer'sity of France. See UNIVERSITIES.

Unkiar'-Skeless'i, a small town of Turkey in Asia, in the neighbourhood of Scutari, gives its name to a treaty concluded July 8, 1833, between Turkey and Russia, by a secret article of which the Sultan undertook to close the Dardanelles against foreign ships of war, thereby permitting the Russians to land in force at Scutari. This treaty was subsequently annulled by that concluded at London, July 13, 1841. See TURKEY.

Unleav'ened Bread was that which, according to the injunctions of the Jewish law, was alone to be used in all offerings made by fire to the Lord (Lev. ii. 4, 11, vii. 12, viii. 2); and there can be little doubt that the shewbread was the same, although it is not expressly stated (*cf.* Jos. *Ant.* iii. 6, 6). Only U. B. was to be eaten by the people also during the seven days of the Passover (Ex. xii.). The reason for these ordinances is not difficult to see. Leaven is simply dough kept till it becomes sour or begins to putrefy, and the process of fermentation which it produces is one of corruption, which would naturally be excluded from all sacred bread.

Unn'a, a town in Westfalen, Prussia, 13¾ miles E. of Dortmund by rail. It has a Protestant and a Catholic church. There are iron foundries, tanneries, weaving-mills, breweries, tobacco manufactories, and the great salt-works and baths of Königsborn. Pop. (1875) 7330. U. belonged to the Hanseatic League.

Unst (formerly *Onyst* or *Ornyst*, Scand. 'eagle's nest'), the most northerly of the Shetland Islands (q. v.), has a length of 11 and a maximum breadth of 6 miles. Area, 35 sq. miles; pop. (1871) 2768. It presents the rocky outline and bleak surface common to the group. Chromate of iron is exported. Fishing and agriculture employ the inhabitants.

Unt'erwalden, one of the three Waldstätten or original cantons of Switzerland, bounded N. by Schwyz and Lucerne, W. by Lucerne, S. by Bern, and E. by Uri. Area, 295 sq. miles; pop. (1876) 27,002. It consists mainly of two great parallel valleys running N. and S. and terminating in the shores at the Lake of Lucerne, each about 15 miles in length, the eastern drained by the Engelberg Aa, and the western by the Sarner Aa. Offsets from the St. Gothard group enclose it on three sides, and separate the basin of the Aar from that of the Reuss, while spurs of the Bernese Alps cover the south, rising in Titlis to 10,427 and in Rothstock to 9620 feet. It is entirely a pastoral country. It exports cattle, hides, honey, and fruits, but chiefly cheese and butter of the finest quality. By the Kernwald the canton is divided into two districts which have been politically distinct since 1150, and which are considered as half cantons, each sending one member to the Ständerath or State Council. They are distinguished, in relation to the Kernwald, as *Nidwalden* and *Obwalden*. The former is made up of the Engelberg valley and the district around the Lake of Lucerne, and has an area of 112 sq. miles, and a pop. (1876) of 11,933; the latter includes the valley of the Sarner Aa and the upper part of the Engelberg valley, and has an area of 183 sq. miles, and a pop. (1876) of 15,009. The government of both divisions is based upon the purest democracy, all legislative power resting in the Landesgemeinde or open-air assembly of all male citizens of full age. The present constitution of Obwalden was adopted by the Landesgemeinde, October 27, 1865; that of the Nid-walden, April 2, 1877.

Unyanyem'bé, a town in Central Africa, capital of a district of the same name, forming part of the country of Unyamuesi. The town of U. is an important settlement of Arab traders, for whose protection a garrison was maintained till lately by the Seyyid of Zanzibar. The houses are substantial, and the Arabs cultivate wheat, onions, and fruit-trees imported from the coast, which is 400 miles distant. The climate is very deadly to Europeans. Pop. 5000. The name U., according to Cameron, signifies 'country of the hoes,' *i.e.*, cultivated country.

Unyo'ro, a kingdom of Central Africa, included between Lake Albert Nyanza, the Victoria Nile, and the kingdom of Uganda (q. v.). The southern and eastern portions are nearly a dead flat, covered with long grass and thick forests of small trees; but the northern and western districts possess a rolling surface and a park-like vegetation. The promontory of Usongara, on the Albert Nyanza, contains a vast salt-field, whence the surrounding lands are supplied. Cattle constitute the chief wealth of the natives, and ivory, which is very plentiful, is the principal trade medium. The climate is moist, and extremely unhealthy for Europeans. The capital, Mrooli, is situated at the junction of the Kafur River with the Victoria Nile, and is a large place, chiefly remarkable for the extreme filthiness of its streets and dwellings, the king's palace being no exception to the rule. See the works of Speke, Baker, and Stanley.

Upan'ishad (=that which underlies the surface), the third and latest portion of the Vedas (q. v.) or primitive revelation of the Hindus. It contains the mystical doctrine of philosophical monotheism, upon which the later systems of metaphysics were based, as opposed to the hymns and ritualistic precepts of the two other parts of the Vedas. About 150 Upanishads are enumerated, of which the most important is called the *Isa*. They are written in prose, with occasional variations in verse. The oldest may reach back to the 6th c. B.C. They are the only portion of the Vedas studied at the present day by orthodox Hindus, as well as by the reformed Theists or Brahmo Somaj. See Muir's *Original Sanskrit Texts* and Prof. Monier Williams' *Indian Wisdom*.

U'pas (Malay, 'poison'), a celebrated tree of Java—the 'Antigar' of the natives of that island, the 'pohon U.' of the Malays, and the *Antiaris toxicaria* of botanists—belonging to the natural order *Artocarpaceæ* (q. v.) or bread-fruit family. After the 16th c. the most exaggerated reports concerning this tree began to reach Europe—that no animal life could exist within range of its effluvia—that no other vegetation was possible within miles of where it grew—that waters in its neighbourhood were untenanted, &c. The naturalists Blume, Horsfield, and Leschenault destroyed the mystery and romance. According to Dr. Horsfield it is one of the largest forest-trees of Java, its white-barked trunk rising to a height of 70 feet before branching. The leaves are lanceolate, the flowers bisexual, the fruits a drupe covered with fleshy scales. On puncturing the bark a yellowish juice exudes, which becomes brown on the surface by exposure. This juice is highly poisonous, and is the principal ingredient of the arrow-poison used by the natives, producing death in fifteen to thirty minutes after introduction into the system. It is said to render the heart insensible to the stimulus of the blood. The flesh of animals killed by it may be eaten with impunity. The inner bark of young trees is made into garments after being carefully cleansed from all the juice. *Antiaris innoxia* of India furnishes ready-made sacks for holding rice. In the Moluccas, another and more terrible poison than the U. above mentioned is obtained from the bark of the root of *Strychnos Tieute*, and is called U. Radja ('the Emperor's poison'). It acts like *Nux vomica*, but in a more intense and violent manner: a tiger struck by an arrow poisoned with it falls in less than a minute.

Uphea'val, the raising of the surface formations by the action of internal forces. U. may be sudden, as in volcanic disturbances, or slow and gradual; as, for instance, the elevation of the coast-line, which may be traced in the raised beaches on our own shores.

Uphol'stery, a branch of industry concerned with the furnishing of houses with beds, curtains and other hangings, carpets, &c.

Upolu,' the principal island of the Samoan Group (q. v.) in the S. Pacific, has a circumference of about 140 miles, and a pop. of about 16,000 A belt of low land skirts the coast, and is succeeded by a table-land which rises inland into successive mountain-ridges, clothed to their summits with the richest verdure. Cotton, cocoa-nut oil, and copra are the chief items of its growing export trade, which is carried on principally with Hamburg. Apia, the capital of the group, is on the N. side of U. It has a fine harbour and many good houses.

Up'sala, a town of Sweden, in the *län* of the same name, 41 miles N.N.W. of Stockholm by rail. It is cut in two by the Fyris or U. River, which, 5 miles below, falls into Ekoln, a bay of Lake Mälar. The chief buildings of U. are the Cathedral (1287-1441), the largest in Sweden, in the interior 360 feet long by 106 to 140 feet broad, with the tombs of Erik the Saint, Gustaf I., Johan III., Linné, and others; the Palace, founded 1548 by Gustaf I., rebuilt after the fire of 1702; the archbishop's

residence; 'Carolina Rediviva,' with a library of 200,000 vols.; the 'Gustavianum,' with lecture-halls and museums; the buildings of the Botanic Institute, the Observatory, the new hospital, and the Cathedral school. After the removal about 1270 of the archiepiscopal see from *Gamla* ('old') *Upsala* (3½ miles N.) to *Oestra Aros*, the latter gradually grew into the modern U., which in the Middle Ages was famous as a place of pilgrimage. It had then four churches, two chapels, two monasteries (one Franciscan, the other of the Holy Spirit), and a priests' college, which in 1477 was chartered as a 'high school.' The Reformation in Sweden was determined by the celebrated 'U. Conference' in 1593, where was also sanctioned the 'High School,' which gradually developed into a University. In April 1878 it had 110 teachers and 1370 students. U. has a 'Latin School,' a lyceum, and a school-teachers' college. Pop. (1876) 13,049.

Uræ'mia. See URINE, DISEASES OF.

U'ral (*Jaik*), a river of Russia, forming part of the boundary between Europe and Asia, rises in one of the highest ravines of the Kalgantau in the South U. Mountains, flows first S. to Orsk, then W. to Uralsk, when it turns to the S. and enters the Caspian Sea by many mouths, after a course of 870 miles. It is scarcely navigated at all, less from its shallowness than from the barrenness and paucity of population of the district through which it flows. The fisheries, however, are extensive. Its principal affluent from the right is the Sakmara (250 miles), and from the left the Ilek (308 miles).

U'ral Mountains (Tartar 'belt,' Lat. *Montes Riphaei*), the longest chain of mountains running N. and S. in the Old World, extending for 1970 miles from the deep basin of the Caspian and Aral Seas, in 48° N. lat., to the coast of the Northern Ocean, and across the Kara Strait into Novaia Zemlia, terminating at 76½° N. lat. They divide themselves into three sections—(1) The Northern Urals, from the Northern Ocean to the source of the Petchora, consisting of wild and rocky mountains, mostly without vegetation, rising in the highest point, Mount Syrty, to 4157 feet. Though only 50 miles in breadth, several parallel chains are formed separated by long valleys crossed transversely by depressions which form easy passes for the transport of the produce of Siberia to Archangel. (2) The Middle Urals, extending S. to the source of the Ufa, a broad table-land rather than a mountain-chain, of moderate height, sloping gradually W. and E. The highest points are Nurtchum (5315 feet), Kirtim (4265 feet), and Kumba (3330 feet). The road from Perm to Jekaterinburg is the principal pass. The mineral wealth of the Middle Urals is great, and consists of gold, silver, copper, platinum, iron, and coal. This district yields one-third of the whole iron produce of Russia. (3) The Southern Urals extending S. in three divisions, the most western of which stretches along the right bank of the Ural river. Its highest points are Iremel (5039 feet), Taganai (3440 feet), and Vurma (3448 feet). See Murchison, *Geology of Russia in Europe and the U. M.* (new ed. Lond. 1853); and Hochstetter, *Ueber den U.* (Berl. 1873).

Uralsk', a Russian town in the district of the Ural Cossacks, on the right bank of the Ural, 150 miles E.S.E. of Samara. It is the seat of a Hetman, has four churches, an important horse and cattle market, valuable fisheries, and a large trade in caviare and tallow. Pop. (1870) 4957.

Ura'nia (Gr. *Ourania*, 'the heavenly one') is the name given in Greek mythology to the Muse of Astronomy. She is called the daughter of Zeus by Mnemosyne, and the mother of Linus and Hymenæus. On medals, &c., she is represented with a celestial globe in her hand, to which she points with a small staff. U. is also the name of a nymph, and a surname of Aphrodite.

Ura'nium (U = 240), a metallic element discovered by Klaproth in 1789, occurs in various minerals, such as pitchblende, uranite, chalcolite, &c. The metal may be obtained either as a black coherent powder or in fused white globules. It has a strong affinity for chlorine and sulphur, forming with the former two compounds, the *uranous chloride* ($U\,Cl_4$) and *uranic oxychloride* ($UO_2\,Cl_2$). The corresponding oxides ($Cl\,O_2$ and $Cl\,O_3$) are bases, and act upon acids to form salts. Uranic oxide also acts as an acid with respect to the more basic metallic oxides, forming a series of compounds known as the *uranites*. These compounds are yellow, and insoluble in water. Sodium uranate ($Na_2\,O\,2UO_3$) is used as a yellow pigment in the glazing of porcelain, and also for colouring glass. Uranic oxide is used for the same purpose, and is the colouring matter of the well-known fluorescent U. glass. The uranous salts are distinguished by their green colour.

U'ranus, the seventh planet in order of distance from the sun, and the outermost but one of all the known members of the planetary system. It was discovered on March 13, 1781, by Sir W. Herschel, who supposed it to be a comet. The calculations of its elements, however, soon proved it to be a planet; and it was then found that it had been observed and recorded as a fixed star no less than fifteen times by Flamsteed, Bradley, Lemonnière, and Mayer. Herschel named it *Georgium Sidus* in honour of George III.; but it was known on the Continent as *Herschel* until the present name was suggested and adopted. The mean distance of U. from the sun is about 1,754,000,000 miles; the eccentricity of the orbit is ·046578; and the length of the year 30686·82 days, or about 84 of our years. The inclination of the orbit to the ecliptic is very small, only 46½ minutes. The equatorial diameter of the planet is estimated at over 33,000 miles, and hence its volume is 74 times that of the earth. The density is, however, only ·17 (the earth's being unit), so that the mass exceeds the earth's mass in the ratio of 12½ to 1. It is hardly possible to observe the time of axial rotation on account of the great distance of the planet; but it has been asserted that the length of its day is between 9 and 10 hours. Four satellites are certainly known. Herschel, however, records the discovery of six; and as two of the recognised ones are quite irreconcilable with any of these, it has been suggested that there are really eight. It is hardly probable, however, that more modern astronomers with their superior instruments should have failed to detect these recorded satellites did they exist; so that it seems likely that Herschel, even with his extraordinary powers of observation, was in this instance mistaken.

Uras'ter, a genus of *Echinodermata*, belonging to the order *Asteroidea*, and including the common star-fish of British coasts (the *Uraster rubens*), along with other species. The disc or body is small, and the arms usually five. The genus U. appears in a fossil condition first in the Oolitic rocks, and has persisted from that period to the present day.

Ur'ban, the name of eight of the Popes.—**U. I.** (date of his pontificate, 223–230) suffered martyrdom.—**U. II.** (Odo of Lagny, 1088–99) was a man of energy and decision of character, and did much to increase the temporal power of the papal see. In 1089 he held a council at Rome at which he excommunicated the Emperor Heinrich IV., together with Clement III. the rival pope, supported by him. In 1090, at a council at Melfi, he caused it to be declared that the laity could not on any pretext establish a right of jurisdiction over the clergy. At the Council of Clermont, in 1095, he further asserted the external authority of the Church and its internal dependence on the central authority at Rome. At this council, too, he fanned into flame the enthusiasm of Latin Christendom for the recovery of the Holy Sepulchre from the infidels. The first crusade (1096–99), ending in the capture of Jerusalem, was the result. U. died at Rome, 29th July 1099. We have fifty-nine of his letters in the *Concilia* of P. Labbé.—**U. III.** (Lambert or Hubert Crivelli, 1185–87) passed his brief pontificate in bitter but indecisive conflict with the Emperor Friedrich Barbarossa—**U. IV.** (Jacques or Hyacinthe Pantaleon, 1261–64), a Frenchman of Troyes in Champagne, spent the three years of his papal rule in attempts to prevent Konrad, the last of the Hohenstaufens, from succeeding to the imperial throne. He wrote a 'Description of the Holy Land,' and sixty-one of his letters are given in the *Thesaurus novus Anecdotorum* by PP. Martène and Durand. See Courtalon-Delaistre's *Vie du Pape U. IV.* (Troyes 1782).—**U. V.** (Guillaume de Grimoard, 1362–70), the last of the popes who resided at Avignon. His pontificate also was troublous, much of his time being passed in not very successful struggles against the Visconti and other powerful lords and princes of the period. Some of his letters are given in the *Thesaurus novus Anecdotorum*.—**U. VI.** (Bartolommeo Prignani, 1378–89). The somewhat rash and inconsiderate reforming zeal of this pope caused the cardinals of the conclave to declare that his election was invalid, and to choose a rival pope, Clement VII., only six months after the election of U. This caused a great schism throughout the Church, the result of which was a conflict that lasted through

the whole of U.'s pontificate. In this conflict U.'s violent disposition gave him a great disadvantage. He died, 15th October 1389, under somewhat suspicious circumstances, and it was generally believed that he had been poisoned.—**U. VII.** (Giovanni Battista Castagna) died 27th September 1590, twelve days after his election and before his consecration.—**U. VIII.** (Maffeo Barberini, 1623–44) was much occupied with the defence of the temporal power. To this end he helped France against Austria and Germany, and was thus brought into somewhat close relations with the German Protestants. He was active also as a priest. He founded the Propaganda (1627), suppressed the order of female Jesuits (1631), caused a new edition of the Romish Breviary to be published, and condemned the theories of Galileo (1633). U. was a zealous patron of art and literature, spoke Greek and even Hebrew with elegance, and was moreover a sacred poet of some merit. Editions of his works have been published at Antwerp (1634), Paris (1642), and Oxford (1726). See *Sylvæ Urbanianæ seu Gesta U. VIII.* (1657).

Urbi'no, a town in the Italian province of Pesaro e U., 20 miles S.W. of Pesaro, on a hill between the Metauro and the Foglia. A market-place occupies the centre of the town. Near it is the cathedral containing valuable pictures, and the Ducal Palace (1477), a magnificent specimen of early Renaissance architecture, with fine-art treasures. The university, founded in 1671, with fifty students in 1877, the Institute of Fine Art, with twenty-nine students in 1877, a library and several important educational institutions (including a normal school with 11 professors and 29 students in 1877), are the other chief buildings. U. manufactures cheese, silk, needles, pottery, and majolica ware. U. was the birthplace of Raffaele Santi, and the house where he was born still stands and was recently repaired. A monument was erected to his memory in 1877. Pop. (1874) 5162, including surrounding villages 16,000. The *Urbinum Hortense* of the Romans, U. was a notable *municipium* in the time of Julius Cæsar. In 1205 U. came under the Counts of Montefeltre, who by Pope Sixtus were made Dukes of U. and were papal vassals. U. was directly under the Popes from 1631 to 1860, when it passed to the kingdom of Italy. See Dennistoun's *Memoirs of the Dukes of Urbino.*

Ur'chin, Sea. See ECHINUS.

Ure, Andrew, M.D., F.R.S., a Scotch chemist, was born at Glasgow, May 17, 1778. He graduated in medicine at Edinburgh University in 1801, became professor of chemistry at the Andersonian Institution at Glasgow in 1804, and was made director of the newly-formed Glasgow Observatory in 1809. In 1830 he removed to London, was appointed analytical chemist to the Board of Customs in 1834, and soon acquired a high reputation both as an investigator and an author. He died in London, January 2, 1857. His chief works are *A New Systematic Table of the Materia Medica* (1813); *A Dictionary of Chemistry* (2 vols. 1821); *A New System of Geology* (1829); *The Philosophy of Manufactures* (1835); *The Cotton Manufacture of Great Britain* (2 vols. 1836; 2d ed. 1861), and a *Dictionary of Arts, Manufactures, and Mines* (2 vols. 1837–39). This last work, rewritten and enlarged by Dr. Robert Hunt (3 vols. 1859-60; 7th ed. 1875, Supplement 1878), is still a recognised authority upon questions relating to the practical bearings of chemistry.

Urea (COH_4N_2), an organic compound forming the characteristic ingredient of urine, from which it was originally obtained. By acting upon concentrated urine with oxalic acid a crystalline solution of the oxalate of U. is obtained, which when dissolved in boiling water and neutralised with carbonate of lime yields solution of U. easily separated from the insoluble calcium oxalate by filtration, and finally concentrated by evaporation, and precipitated by cooling in transparent colourless four-sided crystals. Another process consists in treating the concentrated urine with strong nitric acid, decomposing the nitrate of U. so formed by barium carbonate, and finally dissolving the U. by boiling alcohol, from which the crystals separate out on cooling. U. has a cooling saline taste, is inodorous, and permanent in dry air. It is soluble in an equal mass of cold water, not so soluble in hot, dissolves readily in alcohol, but is insoluble in ether. It fuses at 120° C., and at higher temperatures decomposes into ammonia, cyanate of ammonium, and cyanuric acid. Heated with water in a sealed tube, it yields carbonic acid and ammonia. A solution of pure U. shows no tendency to change by keeping, but if it is associated with putrefiable organic matter it readily decomposes. Hence in putrid urine U. does not exist, but instead there is ammonium carbamate ($CO_3(NH_4)_2$) which contains the elements of U. *plus* two molecules of water. U. may also be formed artificially in a variety of ways, one of the simplest being by heating ammonium carbamate ($CO_2N_2H_6$), which contains one molecule of water less than the carbonate. Hence U. is regarded by Kolbe and other chemists as being the *amide* of carbamic acid, *i.e.*, formed from the acid by substituting amidogen (NH_2) for hydroxyl (OH), or by abstraction of water from the corresponding ammonium salt. Thus the formulæ of carbamic acid and U. may be represented thus—

$$CO\begin{cases}NH_2\\OH\end{cases} \qquad CO\begin{cases}NH_2\\NH_2\end{cases}$$

Carbamic acid. Urea.

A convenient method of preparing U. is to add to strong solution of potassium cyanate an equal quantity of dry ammonium sulphate, evaporate the whole to dryness, and boil the residue with strong alcohol, from which U. crystals separate out on cooling. Its preparation by the action of cyanic acid upon ammonia, as effected by Wöhler in 1828, is interesting as the earliest synthetic formation of an organic compound. The solution of cyanate of ammonium, formed in the first instance when evaporated, yields the U. crystals

$$NH_3 + HCNO = CH_4N_2O.$$

The various amine bases, which are derived from ammonia by replacing one or more hydrogen atoms by corresponding molecules of the alcohol radicals, such as ethyl, methyl, amyl, &c., when treated similarly with cyanic acid, yield a series of substances called the *compound ureas.* Thus from ethylamine, ethyl-urea is formed according to the following reaction:

$$C_2H_7N + CNHO = C_3H_8N_2O,$$

and similarly for methyl-urea, methyl-ethyl-urea, and a great number of similar and even more complex substances. These compound ureas were first systematically studied by Hofmann.

Ure'do, a genus of Fungi formerly including all those now classified under the section *Uridinei* of the natural order *Puccinæi.* This order, in Berkeley's arrangement, has been extended to embrace those parasitic species in which the spawn or vegetative part is reduced to a minimum, and the abundant spores at length form a dusty or more rarely a gelatinous mass. Some of the species, as mildew (see PUCCINIA) and Smut (q. v.), are cosmopolitan. In the section *Uridinei* and *Ustilaginei* the protospores are mostly unicellular, and in the first are disposed in regular orbicular or elliptic masses or *sori;* in the second they form irregular profusely dusty masses. U. in its restricted range has brown or yellow protospores, respectively seen in the common species *U. circæ* and *U. confluens,* which infest the enchanter's nightshade and the dog's mercury.

Ure'na, a genus of rigid tall herbs or shrubs with small pink flowers, belonging to natural order *Malvaceæ.* Besides *U. lobata* and *U. sinuata,* which are common in all tropical regions and are weed-pests in some parts, the genus comprises two or three species confined to tropical Asia. All possess mucilaginous properties, for which some are used medicinally, and the inner bark of some yields an abundance of fibre suitable for gunny bags.

Ure'ter (Gr. *ouron,* 'urine,' and *tērein,* 'to keep'), the excretory duct of the kidneys or tube by which the *Urine* (q. v.) is conveyed to the bladder. The average length of the human U. is from 16 to 18 inches. In thickness the U. attains the dimensions of a goose-quill. It consists of three coats; an outer or fibrous coat, a middle or muscular layer, and an inner or mucous layer.

Diseases of the U.—The most frequent disease of the U. is that caused by the passage of a concretion, formed in the kidney, along the U., towards the bladder. The patient complains of sudden and severe pains in the loins and groin, in the testicles and thigh; and the testes are contracted spasmodically. There is also severe sickness, faintness, and collapse, which may last for several days, or until the calculus has reached the bladder. The patient should be put into a warm bath, chloroform may be administered, and opium or belladonna may be given in full doses. Diluents, such as barley or rice water, may be freely given to wash down the concretion, and fomentations may be applied externally.

Ureth'ra (Gr. the 'urine-passage'), the canal leading from the bladder to the external surface of the body. In the male it attains a length of from 8 to 9 inches, and is divided by anatomists into a *prostatic* or wide portion, a *membranous* part, and a *spongy* portion. The U. consists of three coats, named mucous, muscular, and erectile.

Malformations and Diseases of the U.—The most common diseases of the U. are gonorrhœa and stricture, the special inflammatory conditions of its mucous membrane.

Ur'fa, the modern name of Edessa (q. v.).

Urfé, Anne d', born in Le Forez of an ancient family in 1555, succeeded his father as bailiff of his native country (1574), and having formed an unhappy union with Diane de Château-Morand (annulled in 1598), took orders in 1603, and died in 1621 a canon of Lyon, vicar-general, and prior of Montverdun. The five sonnets published from his *Diane* (1572), and the first book of his *Hymnes* (1608), leave us well content that the bulk of his poems have remained in manuscript.—**Honoré d'U.**, his far more celebrated brother, was born at Marseille, February 11, 1568, and studied at the College of Tournon. A brave adherent of the League, he was twice taken prisoner, in prison commencing his *Epistres Morales* (1598); in 1600 he married his brother's wife, his seven years' senior, that thereby her wealth might not be lost to the family. He fared no better than his brother, and, disgraced at court, retired to Piémont, whence in 1610 he issued part of his famous romance, *L'Astrée.* Modelled on Tasso's *Aminta* and the *Pastor Fido* of Guarini, this work, with its medley of prose and verse, of shepherds, knights, and enchanters, of history and mythology, had a great but now scarce intelligible success. La Fontaine tells how he read it in childhood, and came back to it when his beard was grey. Its second and third parts appeared in 1612 19, the two last were published posthumously by the secretary of d'U., who died at Villefranche in Piémont, June 1, 1625. The latest edition of *L'Astrée* was the Abbé Souchay's (Par. 1733), and translations of it exist in nearly every European tongue. See Bernard, *Les d'U.* (Par. 1839); and Demogeot, *Histoire de la Littérature Française* (12th ed. Par. 1873).

U'rga (Mongol. *Bogdo-Kuren*, 'holy camping-place'), the largest town of N. Mongolia, and the capital of the Khalka Mongols, is situated on the Tola, an affluent of the Orgon, 185 miles S. of Kiakhta. U. is the centre of the Chinese government of N. Mongolia, and since 1604 has been the seat of the high priest (*Kutuchta*) of the Buddhist Mongols. The inhabitants, 30,000-40,000 souls, consist of Lamas (about 10,000), Chinese merchants, officials, and soldiers. Russia maintained here a garrison from 1870-72, and is now represented by a consul.

U'ri, one of the three original Waldstätten cantons of Switzerland, is bounded N. by Schwyz, E. by Glarus and the Grisons, S. by Ticino, and W. by Valais, Bern, and Unterwalden. Area, 415 sq. miles; pop. (1877) 17,041, almost wholly Catholic and German. The mountain system, attaining its greatest elevation in Dammastock (11,910 feet), belongs to the Bernese and Glarner Alps, and is traversed by the St. Gothard Pass, near which a tunnel is now (1879) in course of construction (see TUNNELS). Cattle-rearing is the staple industry, and there is a thriving trade in butter, cheese, hides, and wood. In 1877 the revenue amounted to 479,555 francs, the expenditure to 461,658, and the public debt to 10,722,214 francs. Altorf (q. v.) is the capital. See Lusser's *Geschichte des Cantons U.* (Schwyz 1862).

U'ric Acid ($C_5N_4H_4O_3$), an acid present in the urine of certain animals, and in the solid white excrement of serpents, which consists almost entirely of U. A. and ammonium urate. It is also one of the commonest varieties of urinary calculi, hence its former name *Lithic Acid.* It may be obtained by adding hydrochloric acid to concentrated human urine, from which it crystallises out after some time in the form of small reddish grains very difficult to purify. When pure, U. A. forms a glistening snow-white powder, which under the microscope is seen to consist of minute crystals. It has no taste or smell, and is very sparingly soluble. Its most characteristic chemical feature, by which it may be recognised even when in small quantity, is its action with nitric acid, dissolving in the latter with copious effervescence. The solution, when dried and treated with caustic ammonia, assumes the characteristic deep red tinge of murexide ($C_8N_6H_8O_6$+Aq). U. A. is dibasic, its most important salts being those of the alkali metals, which are all sparingly soluble, and appear as urinary deposits indicating an unhealthy condition of the body. Guano, now imported in large quantities into Britain for use as a manure, is mainly impure U. A. in a remarkable state of decomposition. U. A. has not yet been formed artificially. Chemically, it is remarkable for the facility with which it yields definite and crystallisable organic compounds when treated with oxidising agents, the most important of which are urea, alloxan, uroxanic acid, difheau, alloxantin, parabanic acid, uramil, allanturic acid, &c. These derivatives were first systematically investigated by Liebig and Wöhler, and are important in their medicinal bearings.

U'rim and **Thumm'im**, carried by the High Priest among the Jews, were two objects used by him when consulting the Deity. Some consider that U. and T. was only another name for the breastplate worn on the Ephod (q. v.), but in certain passages they are evidently distinguished from it (Exod. xxviii. 30; Lev. viii. 8; *cf.* Josephus, *Ant.* viii. 3, 8). Whatever may have been the form of the objects, it appears from 1 Sam. xiv. 3, 18, 41, 42, that they were used for casting lots. According to Philo, they were two images of Light (revelation) and Truth (*cf.* Hos. iii. 4, where *teraphim* are mentioned along with the ephod).

U'rine, the fluid excreted from the blood of the Kidneys (q. v.), and which represents in itself the larger portion of the *nitrogenous waste* of the body. The U. passes from the kidneys to the bladder through the *Ureter* (q. v.), and is thus finally got rid of from the system. The subject of the U. may be conveniently discussed in the following order: (1) the characters, physical and chemical, of healthy U.; (2) the conditions affecting the quantity of this secretion; (3) the manner of its excretion by the kidneys. Healthy U. appears as a straw-coloured fluid, possessing at the most a faint aromatic odour. During decomposition this odour becomes strongly ammoniacal, and the fluid itself becomes turbid from the deposition of matter held originally in solution. Only in disease is the U. turbid when expelled at its own normal temperature of 98° or 100° F. At first the U. presents an acid reaction, but by the development of ammonia during decomposition it becomes markedly alkaline. In herbivorous animals the U. is normally alkaline, and generally turbid, a peculiarity depending on the diet, as is found indeed by the U. of carnivorous animals becoming turbid when fed on plant-materials. The *specific gravity* of human U. is about 1·020, but is liable to much variation. From 1·015 in the winter to 1·025 in summer are the usual limits in the variation of healthy U. In some diseases the specific gravity sinks very low. In albuminuria it may stand at 1·004; and in sugary U. or diabetes may ascend as high as 1·050 or 1·060. In 1000 parts of U. 967 parts of water exist, the remaining bulk being composed of (on an average estimate) urea (14·230), uric acid (·468), colouring matter, mucus, &c. (10·167), chemical salts (*e.g.*, sulphates and chlorides of sodium and potass, biphosphates of calcium, sodium, magnesium, ammonium, hippurate of sodium, and fluoride of potass) 8·135, and silica (traces). In twenty-four hours the following are the average quantities of these matters secreted by a healthy male adult: water, 52 fluid oz.; urea, 512·4 grs.; uric acid, 8·5 grs.; hippuric acid, 10 to 15 grs. (?); sulphuric acid, 31·11; phosphoric acid, 45·0 grs.; chlorine, 105·0 grs.; chloride of ammonium, 35·25 grs.; potash, 58·0 grs.; soda, 125 grs.; lime, 3·5 grs.; magnesia, 3·0 grs.; mucus, 7·0 grs.; extractives, 154·0 grs. In any given quantity of healthy U. the quantity of solids may be roughly estimated by doubling the last two figures of the specific gravity. Thus, assuming that 1025 is the specific gravity of the U., then 2×25 gives 50 grs. of solids per 1000 grs. of U. *Urea* is the most important ingredient in U., and represents in itself the chief nitrogenous waste of the frame.

The conditions affecting this secretion and its quantity are—1. The absence or presence of fluids in the food. *Urina cibi* is the U. which is secreted after a solid meal, in which fluid the solids attain a greater preponderance than at other times; *urina potus* is the U. secreted after drinking, where the solids are diminished; and the *urina sanguinis* is that secreted when neither food nor drink has been taken. 2. *Blood pressure* affects the quantity of U. secreted, since whatever increases the flow of blood through the *renal arteries* will increase the quantity of U. secreted, and *vice versâ.* 3. The *period of the day* will affect the U. and its secretions, as also will the *taking of food.* As a rule, U. is secreted more rapidly after meals; less rapidly

during fasting. During sleep the secretion of U. probably reaches its minimum. 4. The *influence of the nervous system and exercise* together affect the secretion of U. very materially. When the skin does not act typically in secretion, as is the case with sedentary persons, the kidneys secrete a greater quantity of U. In summer, when the skin is most active, less U. is secreted than in winter.

The *manner in which the U. is secreted* by the kidneys will best be understood by a reference to the structure of the KIDNEY, described in the article of that name. The *renal arteries* and their capillaries distribute continually a large amount of blood through these glands, and the *Malpighian bodies* or *corpuscles* of the kidney, together with their secreting cells, separate the U. from the blood which circulates through their structures. The U. passes into the bladder in drops, the flow being increased in deep inspiration or during exercise, and also after a meal.

Incontinence of U., or Eneuresis, is a common affection of childhood, which generally yields to domestic management, such as raising the child frequently during the night, withholding fluids during the evening, and the cold hip-bath. The cold douche to the spine is also serviceable, and a blister over the sacrum has been recommended. Belladonna, in doses varying from $\frac{1}{12}$th to $\frac{1}{8}$th of a grain, according to the age of the patient, may be given twice daily, increasing it if required till it produces its constitutional effects. Benzoic acid and chloral are also given in nocturnal incontinence. Ergot is also a valuable remedy in certain cases. Sir Henry Thompson says that in obstinate cases the application of a solution of the nitrate of silver, 10 grains to the ounce, to the neck of the bladder may be beneficial. I. of U. almost always subsides before the patient grows up.

U. in Disease.—The U. in disease may be considered (1) as regards excess or deficiency in any of the normal constituents; and (2) as regards the characters of certain soluble substances, which are never met with in a state of health. *Excess of water.* There are certain affections in which the quantity of water eliminated from the body is greatly increased, such as hysterical affections, and other emotional states. In such conditions the specific gravity of the U. is low. An excess of U. may contain an excess of disintegrated tissue, rendering the specific gravity of the U. normal; but an unusually large quantity of U., of a very high specific gravity, is characteristic of the existence of Diabetes (q. v.). *Deficiency of water* is generally associated with an abnormal quantity of solid matter, usually urea; but when the percentage of solid matter is low, albumen is generally present, and the secreting structure of the kidneys is much impaired. *Acid* U. In chronic and acute diseases the quantity of free acid is generally diminished; but in many cases of pneumonia and rheumatic fever the quantity of free acid is increased. Acid U. may cause the precipitation of uric acid, and of urates in the bladder leading to the formation of Calculus (q. v.); and it may cause irritable bladder, and give rise to a constant desire to void U. *Alkaline* U., in some cases of dyspepsia, arises from the secretion of an abnormal amount of acid by the stomach; and the degree of acidity of the U. may, to a certain extent, be regarded as a measure of the acidity of the stomach. *Excess of urea* is present in those cases in which a specimen of U. yields crystals of nitrate of urea when an equal bulk of nitric acid is added to it in the cold, *without having been previously concentrated. Deficiency of urea* has been observed in cases of ovarian disease and cancer of the uterus. In chronic disease of the kidney, the U. is of low specific gravity, and contains a small proportion of urea. *Uræmia,* depending on the retention of the excrementitious urinary substances in the blood, generally results from long-continued organic disease of the kidneys, but it may depend upon acute disease. *Ammonia* in small quantity passes into the U. from the blood; but in cases of disease it arises from decomposition of U. in the bladder, though more frequently after it has left the bladder. *Colouring matters* formed in the body and excreted in *solution* in the U. are probably derived from the blood corpuscles undergoing disintegration, and from the extractive matters. *Uric acid and urates* usually form urinary deposits, either from existing in too large a proportion to be dissolved in the U. when cold, or from the development of an acid in the U. which causes them to be precipitated from their solutions. In acute febrile diseases there is an excess of uric acid, and in the period of resolution of the inflammation there is an abundant deposit of urates. In gout, uric acid is constant in the blood. *Hippuric acid* is often found in large quantity in diabetes, and seems to take the place of uric acid. *Extractive matters* in U. are entirely excrementitious, and in certain cases there is an extractive matter which has drained away from the blood, and may be detected by the abundant precipitate thrown down on the addition of tincture of galls.

Excess or deficiency of the inorganic constituents.—In *pneumonia,* at the period of hepatisation, there is a total absence of *chloride of sodium;* but after the period of resolution it reappears. The absence of this salt may depend on a determination to the inflamed lung, and reappearance of the salt in increased quantity may depend upon reabsorption. In chorea, rheumatic fever, and in many cases of skin diseases, there is a marked increase in the *sulphates.* It has been conjectured that the quantity of phosphates in the U. varies according to the amount of nervous tissue disintegrated; and that the quantity of work done by the brain is in direct proportion to the activity of the changes occurring in the nervous tissue. The proportion of *earthy phosphates* in the U. does not vary much in disease, but there is an increase in some diseases, as *Mollities ossium.*

Soluble substances which do not exist in healthy U.—Albumen does not exist in the U. of healthy persons, though it may be occasionally present for a short time. *Sugar* in the U. is a prominent symptom of *Diabetes Mellitus* (q. v.); but traces of it are often found in healthy U. It is sometimes present in cases of fatty, wasted liver, pneumonia, phthisis, cholera, and carbuncle. The remaining abnormal constituents of urine are *alkapton, leucine, tyrosine, inosite, acetone, cystine, taurine,* and *hypozanthin. Fatty matter* is found in what is termed *chylous U.;* but the disease is very rare in this country. See Dr. Beale, *Kidney Disease, Primary Deposits, and Calculous Disorders* (Lond. 1869); and Dr. Thudichum, *The Pathology of the U.* (Lond. 1858; new ed. 1877).

U'rmia, a prosperous town of Persia, province of Azerbijan, in a fertile plain, 12 miles W. of Lake U., and 112 miles S.W. of Tabriz. The plain of U. is 50 miles long and 18 miles wide, and is populous and fertile, being well watered by the streams that descend from the Kurdish mountains. The town is girt with a mud wall and moat, and is surrounded for 12 miles round with gardens intermingled with melon, citron, and tobacco grounds. Pop. 35,000 (2000 Jews).

U'rmia, Lake of, a salt lake in Azerbijan, Persia, 3900 feet above sea-level, with a length of 90 miles, a breadth of 30 miles, and a circumference of not less than 250 miles. It contains 6 large and about 50 smaller islands, and receives 14 streams, of which the largest are the Jagatu, Tatau, Sefichai, and Ajichai. It has no apparent outlet. The depth for 2 miles does not exceed 3 feet, the average depth is under 12 feet, the greatest depth ascertained 45 feet. The water is so largely impregnated with salt that no fish can live in it, and the banks are covered with a thick saline incrustation, from which a salt of beautiful transparency is obtained for commerce.

Uro'dela. See NEWT.

Ur'quhart, Thomas, Sir, a Scottish author, best known as the translator of Rabelais, was born probably in 1605. He spent some time in foreign parts while as yet his 'brains were unripened for eminent undertakings,' visiting Spain, France, Italy, and Sicily. In 1639 he was present in Scotland at the battle called the Trott of Turiff, and he shortly afterwards entered the service of Charles I., by whom he was knighted in 1641. On his father's death in 1642, he handed over his Scotch estates at Cromarty to trustees and went abroad; but in 1645 he was obliged to come back to Scotland to look after his affairs, and spent some years in a contest with his creditors. After the execution of Charles I. he joined the royalists, and in March 1649 he was declared a rebel by the Estates at Edinburgh. At the battle of Worcester he was taken prisoner, but he was afterwards released; and after a vain attempt to recover his rightful position in Scotland he escaped to the Continent, where he is said to have died in a fit of laughter at the news of the restoration of Charles II. His translation of the first two books of Rabelais, which appeared in 1653–64, and has been frequently reprinted, is a masterpiece in its style; but his other works are mainly interesting for the strange picture they afford of the writer's mental peculiarities. They were reprinted in one volume of 412 pages for the Maitland Club in 1834:—*Epigrams, Divine and Moral* (1641); *The Trissotetras, or the Most Exquisite Table*

for Resolving all Manner of Triangles (Lond. 1645); *Pantochronochanon, or a Peculiar Promptuary of Time*, tracing the descent of the Urquharts of Cromarty from the Creation (Lond. 1652); *Ekskybalauron, or the Discovery of the Most Exquisite Jewel* (Lond. 1652), written as a vindication of the honour of Scotland, and remarkable for the sketches of Chrichton and other eminent Scotchmen; and *Logopandecteision, or an Introduction to the Universal Language* (Lond. 1653).

Ur'sa Ma'jor, or the Great Bear, one of the forty-eight constellations of Ptolemy, is situated in the northern hemisphere, not far from the N. pole. It is readily recognised by its seven conspicuous stars, four of which form a quadrilateral, and because of the general configuration of these it is popularly known as the Plough or Charles' Wain or Waggon. A line drawn through the last two stars of the quadrilateral passes very near the Pole Star—hence the name given to them, *the pointers*. *Septentrio*, the Latin for U., is evidently derived from these seven stars. *Ursa Minor*, the Lesser Bear, is a generally inconspicuous constellation, in which the Pole Star forms the tip of the tail.

Ur'sidæ. See BEAR.

Ur'son, or Cana'dian Por'cupine (*Erethizon dorsatum*), a genus of *Rodent* quadrupeds, belonging to the family *Hystricidæ*, or that of the Porcupines. The quills are much less typically developed than in the common porcupine. The head is small and flat, and the hairy covering of the body is greater than in the ordinary porcupines. The U. is met with in Virginia and Kentucky as its southernmost limits. In size it attains the length of a foot and a half.

Ur'sula, St., and the Eleven Thousand Virgins, a very curious legend of the Middle Ages, whose origin we may ascribe to the 12th c., and which runs as follows. Deonatus, King of Britain, had a very beautiful and pious daughter named U. She was sought in marriage by the heathen prince Holofernes. His suit was granted, but under the following conditions—the prince must become Christian, and wait for three years whilst the bride-elect went with her companions on a pilgrimage to Rome. The suitor was immediately baptized under the name of Ætherius, and U. set out with eleven vessels, in each of which there were a thousand companion virgins. The company crossed the sea and sailed up the Rhine as far as Basel, from thence they proceeded overland to Rome, where they were honourably received by Pope Cyriakus. The pious and gallant pontiff, along with a multitude of dignified ecclesiastics, accompanied his fair guests a great part of the return journey, and according to some accounts even shared in the final destruction that suddenly overtook the band; for as they were about to land at Koln they were set upon by a horde of heathen Huns, by whom they were all slaughtered. U. was at first reserved as a bride for Etzel, the Hun king, but on her steadfast refusal of the offer she was transfixed by an arrow, and thus she is represented in mediæval art. But the bloody deed was no sooner accomplished than 11,000 celestial warriors appeared, who completely routed the Huns and freed Köln. The citizens buried the unhappy maidens with pious care by the Rhine, held afterwards sacred, and there too Clematius, a Greek pilgrim, built a church in their honour.

The story excited suspicion even in a credulous age. But confirmations were not wanting. St. Elizabeth, abbess of the cloister Schönau, by Oberwesel, held spiritual communication with St. Verena, one of the murdered virgins, and saw the whole tragedy enacted as in a vision. Moreover, Egbert, brother of the abbess, and inspired by her, wrote down an explanation and defence of the story. In this several awkward inconsistencies were smoothed away. Thus there was no mention by Roman chroniclers of a Pope Cyriakus; but this (explained the narrator) was because the cardinals were angry at his leaving the city, and blotted out all mention of him from the records of the Church. If it was asked how the virgins made such excellent sailors, it was replied that King Deonatus had with prudent foresight concealed a number of mariners in the hold of each vessel, and so on. Later critics have striven to explain the vastness of the number. It has been ingeniously conjectured that the number, at first 11, became 11,000 by reading the letter M. (meaning martyred) as the Roman numeral 1000. However this may be, it seems probable that some Christian maidens were really murdered by heathen invaders near Köln, and that the story has thus some basis of fact. No one who is familiar with the literature of the Middle Ages will be surprised at the extravagance of the legend. See Crombach, *U. vindicata* (Köln 1647); Schade, *Die Sage der Heligen U.* (Han. 1854); *Legend of St. U.* (Lond. 1869).

Ur'sulines, The, were one of those religious orders which resulted from the rise in the Romish Church of the evangelical zeal which was so remarkable a reflex effect of the Reformation. Angela or Angelica Merici (1470-1540), a poor maiden of Desenzano, was their founder. She began in that town, and continued afterwards in Brescia, the education of poor children. At the grave of Varallo at Milan, a favourite resort of pilgrims, she was inspired with the determination to found a new religious order, and at the celebration of the mass in the St. Afra Church at Brescia, on the 25th November 1535, the order, as a free union without binding vows, was solemnly inaugurated. Its object was the performance of certain church and household devotions, the instruction of young females, and the bodily and spiritual care of the poor and sick. The order was to be immediately under the supervision of a priest and matron, and Angelica was herself chosen as first matron on 18th March 1537 by the 76 members of the society, and as such she watched over the affairs of the order till her death, three years later, when she was succeeded by the Countess Lucrezia of Ladrone. On 9th June 1544 the order received papal sanction from Paul III., and in 1584 it had increased to 600 nuns in 18 establishments. It quickly spread itself from Italy into other lands, and at the beginning of the 18th c. had 20 congregations, 350 convents, and from 15 to 20,000 nuns. It was not quite the same in all countries, and was never bound together so strictly as other religious orders were. No general assembly or provincial chapters were held, so that each settlement of the U. stood under the power of the bishop of the diocese. One of its latest developments was the congregation of Chavagnes, in La Vendée, founded by Demoiselle Brechard in 1805, and containing, in 1862, 300 to 400 sisters in about 30 houses. See *Les Chroniques de l'ordre des U.* (Par. 1676); *Journal des illustres Religieuses de l'ordre de Ste. Ursula* (Par. 1690); *Auf.-und Fortgang des jungfraülichen Ursulenerorden durch G. A. Mayer* (Wurzb. 1692).

Urtica'ceæ, or **Urti'ceæ**, a natural order of apetalous dicotyledons, either herbs, shrubs, or trees, with watery juice, alternate or opposite leaves, and small green unisexual flowers. There are about 500 recognised species, comprised in 43 genera. U. is represented in all climates, but principally temperate and tropical, and mainly in the latter. A characteristic of the order is the valuable fibre of the inner bark. See BOEHMERIA and RHEEA FIBRE. Sometimes the plants bear stinging hairs, as in the common British Nettle (q. v.) and the Neilgherry Nettle (q. v.). None of the species are medicinal.

Urtica'ria. See NETTLE RASH.

Uruguay', a large river of S. America, rises in Brazil in 28° 40′ S. lat., only 100 miles from the Atlantic, and flows successively N.N.W., S.S.W., and S. till it unites with the Parana (q. v.), to form the Rio de la Plata. The total length of the U. is about 900 miles, but shoals and rapids prevent large vessels from ascending it beyond Concordia, 200 miles from its mouth. It has a rapid current, and a volume nearly as great as that of the Parana, to whose turbid waters its clear stream presents a marked contrast at their junction. For nearly three-fourths of its length the U. separates the Argentine Republic from Brazil and the republic of U. See *The Paraná, the U., and La Plata Estuaries*, by J. J. Révy (Lond. 1874).

Uruguay', a republic of S. America, bounded N. by Brazil, E. by Brazil and the Atlantic, S. by the Rio de la Plata, and W. by the Argentine Republic. Its area is 72,151 sq. miles, and its pop., at the census of 1878, 440,000. The southern half of the country is rolling and open, with few trees, and traversed by low ranges of hills. N. of the Rio Negro, the country is still little known, but is more hilly and wooded. The streams are commonly lined by dense thickets, in which lurk the jaguar and ounce, and the other wild animals include the tapir, deer, fox, and dog. Sheep were formerly reared in great numbers, and their wool was much esteemed, but of late years the sheep-farming interest has greatly declined, the sheep giving place to cattle, for which the coarse pastures of the country are better suited. Owing to the insecurity of life and property, labour is very scarce, and agriculture is consequently limited, but the soil and climate are alike

most favourable for the growth of wheat, maize, cotton, tobacco, and the vine. Beef, jerked and salted, extract of meat, hides, horns, hair, tallow, wool, and feathers, are the chief exports, whose value in 1875 was £2,644,591, while that of the imports was £2,800,416. In 1878 there entered at ports of the United Kingdom, 48 vessels of 17,535 tons employed in the trade with U., and cleared 220 of 157,649. A central line of railway 130 miles long connects Monte Video (q. v.), the capital, with Duragno, and is being slowly extended westward to Higueritas, near the mouth of the river U., 136 miles distant. In the N.W. a railway is being made parallel to the same river, from Salto to Santa Rosa (108 miles). The country is divided into nine departments, and next to the capital the most important towns are Colonia and Maldonado, both on the S. coast. U. was first settled by colonists from Buenos Ayres, and after a contest for possession between Spain and Portugal, was attached to the former's vice-royalty of Buenos Ayres with the name of *Banda Oriental* ('eastern bank') *del U.* Its independence as a republic was secured by a treaty dated 27th August 1828, and its subsequent history is a miserable record of perpetual civil war and growing financial difficulty. See Petermann, *Die Sudamerikanischen Republiken, Chili, Paraguay, and U.* (Gotha, 1873); Diaz, *Notice historique et statistique sur la République Orientale de l'U.* (Par. 1878); Muthal, *Handbook of the River Plate Republics* (Lond. 1878).

U'rus, a species of wild oxen, popularly named the 'Mountain Bull,' and supposed to be the immediate progenitors of the famous Chillingham cattle. The U. existed in a wild state and in large numbers in Gaul at the period of its invasion by Cæsar, whose description of the animal is obviously exaggerated.

Usamba'ra, a country of E. Africa, lying between 4° 20'—5° 25' S. lat., and 38° 20'—39° 10' E. long. Its most southerly point is only 50 miles N.W. of the city of Zanzibar (q. v.). U., which has been called 'the Switzerland of Africa,' is a mountainous country traversed by four parallel ranges running N. and S., and forming a part of the great coast-range which stretches from Abyssinia to Natal. The mountains, which are of volcanic origin, reach a maximum height of 6000 feet, and are usually clothed with trees to their summits. The country is well watered, the soil extremely fertile, the vegetation luxuriant, and the scenery of the loveliest description. A level plain 30 miles wide separates the mountains from the sea. Rice, maize, semsem seed, indiarubber, and tobacco are exported, and cotton of good quality is also indigenous, but is not cultivated. The country, lying on the shortest route to Lake Victoria Nyanza, is likely to rise in importance as the civilisation of Eastern and Central Africa advances. See the *Proceedings of the Royal Geographical Society for* 1879.

Use, at common law, was a beneficial interest in land distinct from the ownership, introduced from the civil law by the clergy. The device was to convey land to some one for the U. of the Church. In this way the prohibition against Mortmain (q. v.) was avoided.

Use and Occupa'tion, a term of English law denoting the advantage accruing to a tenant from occupying the premises of his landlord. When there has been no lease, or when the terms of the contract of letting are ambiguous, the proper mode to recover rent is by an action for U. and O. An action cannot be maintained for the rent of premises let for an illegal purpose; and an immoral purpose is illegal.

U'sedom, an island of Pommern, Prussia, opposite the harbour of Stettin. Its form is irregular, and with a length of 34 and a breadth of 15 miles, it has an area of 148 sq. miles; pop. 25,000. Swinemünde (q. v.) on its N. and U. on its S. side are the only towns. The latter had a pop. (1875) of 1738.

U'ses and Trusts, in English law, correspond to the *Fidei Commissum* (q. v.) of Roman law.

Ushant (Fr. *Ouessant*), a small island, about 11 miles off the coast of Brittany, gives its name to the group of which it is the largest, all of which are included in the department of Finisterre. U. has an area of about 3800 acres, and affords admirable pasturage for cattle, but contains no wood. A lighthouse has been built upon the island, off the S. coast of which is a dangerous eddy, locally known as the *Fromveur*. Pop. (1872) 2377, all fishers.

Ush'er of the Black Rod, an officer of the Order of the Garter, who usually holds the office of the first Gentleman Usher at Court, in which capacity he is one of the chief officers in the House of Lords. He wields an ebony rod, from which his title is derived, and has a mantle like that of the Garter King-at-Arms. His deputy is called Yeoman Usher, and among the functions devolving upon him or his deputy are the summoning of the Commons to the House of Lords when the royal assent is to be given to bills, and the execution of orders of committal for breach of privilege.—The **Usher of the Green Rod**, an officer of the Order of the Thistle, attends on the sovereign and knights assembled in chapter.

Uskup' (anc. *Skopia*), a town of European Turkey, vilayet of Prisrend, on the river Vardar, and on the Salonika-Mitrovitza railway, 130 miles N.N.W. of Salonika. It is the seat of an archbishop, and has manufactures of leather, and a pop. of 20,000.

U'snea, a genus of lichens with a rounded, branched, and generally pendulous thallus bearing terminal shields (*apothecia*) containing the spores. They grow on rocks and trunks of trees, and from their appearance have obtained the popular name of 'beard-moss' and 'tree-hair.' Some of the large-growing species of the southern hemisphere are very handsome. Three species are British, *U. barbata* being common and multiform.

Ussh'er (commonly **Usher**), **James**, a very eminent scholar and prelate of the Irish Episcopal Church, was born of good parentage at Dublin, 4th January 1581, was educated at Trinity College, took orders in 1601, and continued for some time afterwards at college, where he studied the Fathers with care and zeal. In 1603 he went to England on university business, and remained there three years. In 1607 he was appointed Professor of History at Trinity College; in 1612 he was made Doctor of Theology; and in 1614 Vice-Chancellor of Dublin University. In 1615 a general synod of the Irish Church was held, at which 104 articles of faith were agreed upon. These articles were drawn up by U., and differed much from those of the sister church in England. In 1621 U. was made Bishop of Meath, but he did not long exercise episcopal functions there, for in 1623, having obtained the king's permission, he came to England to study sources of information regarding the history of the early British Church. Whilst there the see of Armagh fell vacant, and in March 1625 U. was appointed Archbishop of Armagh and Primate of all Ireland. U. soon found the honour a burden almost too grievous to be borne. The Roman Catholics were in a state of active discontent, and they nearly succeeded in bullying and frightening the English government into granting them toleration. U. was bitterly opposed to this, for he held that the Pope was Antichrist, and he wrote and preached against it on every opportunity. In 1633 Wentworth, Lord Strafford, came as Viceroy to Ireland, and in pursuance of plans arranged by Laud proceeded to force the Irish Church into closer conformity with that of England, and in this, notwithstanding U.'s opposition, he was to a great extent successful. In 1640 U. left for England. The Civil War almost immediately broke out, and he never returned. Shortly after his arrival at Court he drew up a scheme of reconciliation to unite Churchmen and Dissenters. The concessions which U. proposed showed him to be a man of a liberal and tolerant spirit, at least towards his fellow-Protestants. He passed the greater part of the Civil War in obscurity. From the top of the Countess of Peterborough's house he witnessed with horror the execution of his sovereign. U. died in London, 21st March 1656, and by command of Cromwell was buried in Westminster Abbey. The writings of U., which are tolerably voluminous, may be classified under four heads—1, Apologetical and polemical; *e.g.*, *Gravissimæ Questionis de Christianarum Ecclesiarum in Occidentis præsertim partibus ab Apostolorum temporibus ad nostram ætatem continua successione et statu historica explicatio* (1613), and *An Answer to a Challenge made by a Jesuit in Ireland, wherein the Judgment of Antiquity in the Points Questioned is truly delivered, and the Novelty of the now Romish Doctrine plainly discovered* (1625). The purpose of these and some lesser writings was to show that the pure Church of Christ had existed right on from the death of its Founder apart from the Romish Church. 2. Archæological and church historical; *e.g.*, *Britannicarum Ecclesiarum Antiquitates* (1639, enlarged ed. 1677). This work, the fruit of twenty years' labours, contained an account of the British Church down to the 7th c. To the same class also belong

editions of parts of the Fathers and dissertations on their writings. 3. Chronological.—The chief of these is the *Annales Veteris et Novi Testamenti* (1650-54), a work of vast learning and research, containing a chronology of the whole Scripture. It is from this work that the dates so often printed on the margin of our English version are taken. 4. Miscellaneous, containing writings on ecclesiastical law and polity, &c. U. was a man of vast learning and of great historical acumen. Though he held his opinions firmly and expressed them openly, he was respected by the most opposite parties. Indeed, his doctrines were somewhat eclectic, for though a strong Calvinist he yet held the doctrine of the Real Presence. But the reverence in which he was held was not due to this, but rather to his spotless purity of life and the genuine benevolence of his disposition. See his *Complete Works*, with life by Dr. Elrington, Professor of Divinity in Dublin University (16 vols. 1847).

U'sufruct, a term of Roman law adopted by the law of Scotland. It has essentially the same meaning as *Liferent* (q. v.). In English law, see TENANT FOR LIFE.

U'sury is the taking of more than a legal rate of interest on a loan of money. The Act 17 and 18 Vict. cap. 90 repeals all the Acts against U. See under INTEREST, *Law Regarding Interest of Money*.

U'tah, an organised Territory of the U.S., lies mainly in the great Wahsatch basin, between the Rocky Mountains and the Sierra Nevada, and is bounded N. by Idaho and Wyoming, E. by Colorado, S. by Arizona, and W. by Nevada. Area, 84,000 sq. miles; pop. (1850) 11,380, (1860) 40,273, (1870) 99,581, (1874) 130,000, of whom 115,000 were Mormons, and 13,538 Indians and negroes. U. is 350 miles long from N. to S. by 300 broad, and is traversed from N. to S. by the Wahsatch mountain-range, the E. wall of the Great Basin, which is confined on the W. by a lower range, bearing various local names, as Raft River, Cedar, Goshoot, Wah-Wah, Needle, &c. Beyond this latter range, and in the extreme end of the elevated plateau, much of the surface is alkaline desert, bearing only sagebush or greenwood, except where irrigation has rendered it productive of large crops. The Great Basin has an elevation of from 4250 to 6000 feet, and the Wahsatch attains a total height of 13,000 feet in the snow-clad Nebo and Twin Peaks. To the E. of the Wahsatch lies a plateau, 6000-7000 feet in elevation and some 40 miles wide, sloping towards the upland valley in which San Rafael, Uintah, Dirty Devil, and other rivers rise, forcing their way through cañons varying in depth from 2000 to 5000 feet. These rivers unite in the Rio Colorado of the W., which gives its name to the Great Cañon, a narrow, tortuous chasm, 300 miles long. The drainage of the Great Basin is received by a congeries of large lakes, of which the chief are Great Salt Lake (q. v.) and U. Lake. The former contains 22 per cent. of pure salt, and is therefore destitute of fish, while the latter, with which it is connected by the Jordan, 45 miles long, has pure fresh waters. The Preuss River, flowing into Preuss Lake, and Rio Virgen, a branch of the Colorado, water the S.W. part of the Territory. The formation of the mountains is chiefly Eozoic, of the Great Basin and upper valleys Tertiary, and of East U. Cretaceous, except when the cañons reveal strata reaching down Silurian rocks. U. is rich in precious metals, and in spite of the obstructive policy of the Mormons mining enterprise is rapidly extending. In 1871 no fewer than ninety mining districts were opened, and in 1877 the yield of bullion amounted to $8,113,755. There are larger deposits of iron ore than in any other part of the U.S., the quantity contained in one district of Iron county alone having been estimated at 130 million tons. Castle Valley district, on Green River, is equally rich, and in the N. are other vast deposits. These deposits comprise hæmatite and magnetic ores of fine quality, and both lignite and excellent bituminous coking-coal exist in their vicinity, as well as fluxes and other requisites for smelting. The lignites of the Great Basin are valuable for fuel, but do not coke; the cañons of Green and Grand Rivers contain bituminous coal in thick workable seams. Copper and zinc abound in U., which also produces much salt, sulphur, carbonate of soda, alum, borax, &c. Salt is largely procured by evaporation from the lakes, but rock-salt is also present in vast quantities. The mean temperature ranges from 48·65° in the S. to 51·51° in the N.; at Coalville it is 69·2° in summer and 21·9° in winter, and at Salt Lake City, 75·9° in summer and 32·1° in winter. The Great Basin is almost rainless, but in East U. the yearly fall is 15·10 inches. The animals are those peculiar to the Rocky Mountains (q. v.); the sage, hare, and 'Baird's rabbit,' are notable. The hills are wooded nearly to the snow-line, but there are in all only 4000 sq. miles of timber. The trees of the Basin resemble those of the Pacific slope, but do not attain the greatest dimensions. The Mormon system of irrigation is singularly effective, and, in 1874, 250,000 acres were under crops. The yield in 1874 comprised 2,000,000 bushels of wheat, 350,000 of barley, 700,000 of oats, 375,000 of Indian corn, 2,000,000 of potatoes, 300,000 tons of hay, and a valuable crop of fine fruit—total value, $6,000,000. In 1870 U. had 14,281 horses, 2879 mules and asses, 190,934 neat cattle, 59,672 sheep, and 3150 swine—value $2,149,814. The industrial products are iron and iron goods, flour, lumber, and woollen goods. In 1875 U. contained 596 miles of railway (Union-Pacific and branch, S. by Salt Lake to Provo), besides 350 irrigating canals, constructed at a cost of $2,225,000. Salt Lake City (q. v.) is the capital, and other towns are Ogden, Provo, Lehi, Mount Pleasant, and Iron City. U., named from the Utes, a tribe of Indians, was ceded by Mexico in 1848, in which year it was settled by the Mormons (q. v.). It was organised as a Territory in 1850, but the demand of the Mormons for its admission as the 'State of Deseret' was refused in 1862. The legislature is still wholly composed of Mormons, and at various times it has come into collision with the U.S. Congress on the subjects of supreme authority and the recognition extended to polygamy. An investigation into the shocking massacre of settlers by Indians, which occurred in Santa Clara (1857), was begun by the Government in 1875, some fresh revelations pointing to Mormon instigation.

U'terus. See WOMB.

U'tica, a Tyrian colony founded about 1100 B.C. on the N. coast of Zeugitana in Africa, near the mouth of the Bagradas (*Mejerdah*), and 27 miles N.W. of Carthage. It figures as the latter's ally or dependant in treaties from 509 to 215 B.C., but, having aided it in the two first Punic Wars, seceded in the third (149-46 B.C.), and thenceforth was the chief town of the province and a great emporium of Roman commerce. Created a *civitas* by Augustus and *colonia* by Hadrian, it received from Septimus Severus the *jus Italicum*, was the see of a Christian bishop (256-684 A.D.), and was finally destroyed by the Saracens. At the modern *Duar* are the remains of its amphitheatre (seating 20,000 spectators), of an aqueduct, and of numerous temples.

U'tica, the capital of Oneida county, New York, on the S. bank of the Mohawk river, 96 miles W. of Albany by rail. It is situated on the Erie Canal, is the terminus of the Chenango Canal, and immediately to the S. are rich deposits of iron ores, which are now wrought on an extensive scale. Lying in a productive dairy-farming district, it is the chief market for cheese in the United States, having sold 200,000 boxes, or $1,735,592 worth, in 1875. The industrial products are woollens, cottons, ready-made clothing, boots and shoes (630,000 pairs yearly), steam-engines, stones, lamps, farm-implements, millstones, and drain-tiles. There are three fine parks within the town, and an excellent driving park on its eastern boundary, while the water-works have a capacity of 400,000,000 gallons annually. In 1878 U. had 32 churches, at four of which the service was in Welsh and at six in German. The periodicals number two daily and three English weekly, a German tri-weekly, a Welsh weekly, and two Welsh monthlies. Pop. in 1870, 28,804; in 1875, 32,070. U. was settled in 1787 and incorporated in 1798.

Utilita'rianism is that theory of life which represents happiness as the only ultimate end to be desired and sought after—not necessarily the happiness of the individual, but that of the human race as a totality, and 'even as far as possible of the sentient creation'—in Bentham's phrase, 'the greatest happiness of the greatest number.' The theory as one of moral action asserts—'Actions are right in proportion as they tend to promote happiness, wrong as they tend to produce the reverse of happiness' (Mill's *U.*). Like all other systems, U. is best looked at from the point of view of its historical development. We find its first statement as a philosophical theory among the Greeks. It is presupposed in the philosophy of Socrates (q. v.), or rather it unconsciously underlies that philosophy; but to claim Socrates as an adherent of U. is to apply modern conceptions to ancient ideas, and the result is only misleading. The same remark applies to Aristotle (q. v.), who asserted that the absolute end

(*telos*) of human action is happiness; since the statement is almost meaningless, unless taken in accordance with the whole teaching of his philosophy. In Epicurus (q. v.) we recognise a true adherent of U. He 'sought the *summum bonum* in felicity of life;' not, indeed, in any low sense, since he held that pleasure was a certain fair even satisfaction and calm, extending over the whole life, and did not consist of moments of ecstatic joy. Still, all happiness is thus reduced to a strictly individual system, and the gaps in this as well as in the opposite (Stoic) system are strikingly represented in the paradox, common to both, of the wise man happy on the rack. Thus U., as far as it was capable of development as an individual system, received that development in Greece. For its further development we must refer to the last three hundred years of English thought.

Hobbes (q. v.) enunciated with startling plainness a system of individual selfishness. 'Whatsoever is the object of any man's appetite or desire, that is it which he for his part calleth good, and the object of his hate and aversion evil; and of his contempt rude and inconsiderable.' Each man, continues Hobbes, must settle for himself what is right and wrong according to his individual pleasure; or if there be a collision of interests, he must concur in the appointment of some arbiter (the State) who shall settle what is right and wrong for him. With Paley (q. v.) U. took a theological aspect. Virtue he defined to be 'the doing good to mankind, in obedience to the will of God, and for the sake of everlasting happiness.' This particular development of U. is deserving of more attention than it usually receives, Paley only consciously stated what the great majority of his countrymen unconsciously believed, for this practical definite form is exactly in accordance with the English mind. As a proof of this it may be noted that men so widely removed from Paley and from each other as Berkeley (q. v.) and Butler (q. v.), assume without a doubt a moral system analogous to this. With Jeremy Bentham (q. v.), the inventor of the term the 'greatest happiness of the greatest number,' as the end of all true moral action, U. takes its more modern shape. 'Nature,' he said, 'has placed mankind under the government of two sovereign masters, Pain and Pleasure. It is for them alone to point out what we ought to do.' In J. S. Mill (q. v.) U. assumes its present, which may be safely said to be its highest, form. There, the happiness of the race is announced as an end to be pursued by the individual, even though he should be obliged to renounce his own in its attainment. A place is found for the martyr's effort, but that effort must be in accordance with the great principle of U., or it is worse than useless. Moreover, happiness is here no low or degrading conception, for there is *quality* as well as *quantity* in pleasures, and a lower pleasure must yield to a higher—the senses to the intellect, the body to the mind. Those who have had experience of both may be taken as judges of the question. They have uniformly given the palm to the higher pleasures, and from their decision 'I apprehend there can be no appeal.' By careful moral education the conscience of the individual is to be so developed that its force in the direction of right action will be all-powerful.

That U. is a theory of great plausibility, and that it can urge a great deal in support of its position, is evident from the preceding historical sketch. It is, so to speak, a self-contained theory; it does not require to go beyond the obvious facts of existence to support its claims; it is plain, simple, and direct; it affords an easy and safe rule for the solution of all disputed questions of morals; and it is in obvious agreement with a vast number of the most patent facts of life. Many arguments have been employed against U. It has been urged (1) that our powers have various ends, how then can happiness be the end of them all? (2) that all actions producing happiness are not regarded as moral actions. All actions producing pain are not wrong actions; (3) that pain may be used as a means to good, but we must not do evil that good may come of it; (4) that we cannot always calculate beforehand whether the effects of an action will be good or bad. Human life is too complex, and the knowledge an individual has of it is too small to allow him to judge with perfect certainty. Besides, men will take different views of such questions, and thus the moral standard will at best be but a fluctuating one. These objections have been more or less effectively met by the advocates of U., but the gravest objection to the doctrine is (5) that it has no proper theory of duty—the word 'right' has no deep true meaning in this system. This will appear from a little reflection. If my interest conflicts with that of the race, if it urges me to do an immoral act, shall I not simply show strength of intellect and a wise perception of my own individual position if I disregard anything but my own interest? My conscience, it is true, tells me not; but what is this conscience? According to Professor Bain's analysis, it is a triple compound placed in me by education, and composed (1) of fear, since the child finds its wrong-doing punished; (2) of respect, since the child respects those who are older and wiser, and who instruct and guide; (3) of utility, since the child finds when it grows up that the prohibitions and commands laid upon it in infancy had a deep and wise meaning. Mill, by an analysis substantially similar, says that a feeling, a pain more or less intense on the violation of duty, is of the essence of conscience, and that this feeling implanted by education is one of sympathy and fellow-feeling with the race. Now, all this is true no doubt, but still it hardly covers the difficulty. Conscience may consist of any combination of feelings, however powerful and sacred, but will not their disregard on convenient occasions be simply an exhibition of rational strength? This, then, is a weak spot in U., a joint in the harness, and unfortunately just over the heart of the system. The best answer that can be attempted seems the following:—On a utilitarian theory it must be admitted that there is no such thing as absolute good or evil, or absolute moral duty. But humanity has created a morality for itself, and he who departs from it is a wrong-doer, inasmuch as he sins against the race. This relative right- and wrong-doing is all that the circumstances of the case admit. It is to be noted that in the later utterances of U. the religious element is only introduced in a side manner. Of course, in a theory like this, all the difficulty as to a motive force is got over when we adopt a system like Paley's; on any other system, the answer must be as given above. It is to be carefully noted that even if we reject U. we are not forced to adopt the contrary system of Intuitionalism. The systems are contrary, and not contradictory; they may both be false, though both cannot be true. See J. S. Mill, *U.* (new ed. Lond. 1871): J. Grote, *An Examination of the Utilitarian Philosophy* (edited by J. B. Mayor, Lond. 1870); Birks, *Modern U.* (Lond. 1874); Sidgwick's *Methods of Ethics* (Lond. 1874); and Calderwood's *Handbook of Moral Philosophy* (5th ed. Lond. 1878).

Uto'pia (Gr. 'nowhere') is the name given by Sir Thomas More (q. v.) to the island which is the seat of his ideal commonwealth, whose merits put to shame the imperfections of European states. From it we derive the adjective 'Utopian,' applied to any scheme or idea which is, or is supposed to be, impracticable. The word is often rashly used. Every reform in religion, government, or society has had to pass through a 'Utopian' phase.

U'traquists. See CALIXTINES.

Utrecht', a province of Holland lying S. of the Zuider Zee, and bounded E. by Gelderland, S. by South Holland, and W. by North Holland. Area, 532 sq. miles; pop. (1877) 188,522 (three-eighths Protestant, two-fifths Roman Catholic). The surface is in general flat, and somewhat marshy in the W.; in the E. is the low range of Amersfoort. The chief streams are the Rhine, with its arms, the Krummen or Old Rhine, Vecht, Yssel, Leck, and the Gem, which falls at Bunschooten into the Zuider Zee. Many canals intersect the province, most important of which is the Baart, connecting the Leck with the Vecht. The chief productions are corn, tobacco, and honey. Cattle and horses are exported. There are manufactures of woollens, cottons, linens, silks, tobacco, and clay wares.—**U.**, capital of the preceding, and one of the oldest towns in Holland, on the Old Rhine, two arms of which intersect the town, and which is connected by the Vecht with the Zuider Zee and by the Baart with the Leck, 23 miles S.S.E. of Amsterdam by rail. It is surrounded with strong forts, around which are beautiful promenades; it has four suburbs, and in its E. quarter is the Maliebaan, a fine six-rowed avenue of lindens., with handsome villas on each side. It has twenty churches, including the Gothic cathedral Maartenskerke, the nave of which was thrown down by a hurricane in 1674, so that now the choir and the tower stand separate. The tower is 321 feet high, and has a chime of forty-two bells. Among the other buildings are the Academy, in the great hall of which the union of the northern provinces was concluded in 1579; the palace of Louis Buonaparte, king of Holland, who chose U. for his residence, now the seat of the supreme military court; the Paushuizen, or Pope's

house, built by Pope Adrian VI., who was born at U. in 1459; the Palace of Justice, erected in 1837 on the site of the celebrated abbey of St. Paul; and the Stadhuis, built in 1830, with a rich collection of national archives and antiquities. The University was founded in 1634, and had, in 1871, 23 professors and 481 students. It has a library of 50,000 vols., a botanical garden, an astronomical and a meteorological observatory, a natural history museum, a chemical and a physical laboratory. U. has a gymnasium, a veterinary and a technical school, a picture-gallery, a theatre, and a hospital. Its industries are metal-founding, tile-burning, dyeing, linen and silk weaving, and the manufacture of woollens, cottons, porcelain, chemicals, machinery, and agricultural implements. T. has also an active trade in agricultural produce, especially cheese and butter. Pop. (1876) 65,052. U. was the *Trajectum ad Rhenum* of the Romans. It was given in 696 to Bishop Willibrod by Karl Martel, and was made in 1559 the metropolitan church by Pope Paul IV. Under the rule of Philip II. of Spain was concluded at U. the union of the Seven United Provinces, which was the foundation of the independence of the Netherlands. At U. was concluded, April 15, 1713, the treaty which brought to a close the war of the Spanish Succession. See SUCCESSION, WARS OF.

Utre'ra (*Verculum*), a town of Spain, province of Seville, 18 miles by railway S.E. of the city of Seville, was at one time a place of some celebrity, but is now much decayed, though still important as a military post. It contains a fine Gothic church, a Moorish palace, and cavalry barracks. In the environs olives are grown largely. Pop. 12,900.

Utt'ering, in law, signifies the making use of a forged writing (see FORGERY), or the passing, or attempting to pass, a base coin as a true one. Forgery is not completed without the U. It is criminal to utter false foreign coin.

Uttox'eter, a town of Staffordshire, England, near the Dove, 16 miles E.N.E. of Stafford by rail. The parish church still possesses an ancient tower and spire, but it was rebuilt in 1828, and its chancel was extended in 1877. Other buildings are the town-hall (1855), mechanics' institute, and free grammar-school (1859). The Caldon Canal ends here. Breweries afford employment to many hands. Pop. (1871) 3604.

U'vula. See PALATE.

Uva-Ursi. See ARCTOSTAPHYLOS.

Ux'bridge, a town of Middlesex, England, on the Colne, 15¾ miles W. of London by rail. The ancient church of St. Margaret was restored in 1872 by Sir G. G. Scott, who also designed St. Andrew's (1865), with a spire of 170 feet; and a spacious Corn Exchange was erected in 1861. A large weekly corn-market is held here. Pop. (1871) 7407.

Uz'beks, the dominant race of Turkestán, of purely Turkish descent, constitute the military and governing class in Khiva, Bokhára, and Khokan, and by Meyendorff were estimated at 1,500,000 souls. Partly nomad and partly sedentary, the U. are distributed by Vámbéry into thirty-two tribes, of which the chief are the Ming (to which the kháns of Khokan belong), the Chagátáis of Namaghán, the agricultural Kuiúmas on the river Sír, and the Kipchaks, almost extirpated in 1853, up to which date they had stood at the head of the race. The U. have less of a Tartar aspect than the Kirghiz, but in Bokhára are much infused with Tagik blood. Brave soldiers, they are to a man fanatical Mohammedans. In history they first emerge shortly after the death of Timur (1405), and now, after holding the predominance for over three centuries, they have for the most part passed to Russia by its annexations of Bokhára, Khiva, and Khokan (1866-75). See TURKESTAN, and Von Hellwald's *Russians in Central Asia* (Eng. trans. Lond. 1874).

V.

the twenty-second letter of the English alphabet, occupying the same place as in Latin. Its form is derived from the Greek υ or Υ; but its phonetic value is rather identical with that of the Semitic Vau and the archaic Greek digamma, which is also represented by F (q. v.). It bears the same relation to U as the consonant J does to the vowel I, and in both cases the form of these pairs was originally identical. In German it is pronounced soft, like our F; and probably this is its proper phonetic value. In Latin it has a tendency to disappear by elision; *e.g.*, *non volo*=*nolo*, and *providens*=*prudens*. Its commonest interchanges are with U, F, and B. *Cf.* 'solve' and 'solution;' *navita* and *nauta*; Lat. *cervus*=Fr. *cerf*; Lat. *vervex*=Fr. *brebis*. The numerous instances in which a Latin V represents a lost Greek digamma, such as *vinum* for *oinos*, *videre* for *idein*, are really examples of the interchange between V and F. In Greek, V is transliterated by *ου* or by *β*.

As a numeral, V stands for five, being supposed to represent the outstretched fingers of one hand. As an abbreviation, V. in English stands for Victoria, as V.R. = Victoria Regina, V.C. = Victoria Cross.

Vaal, an important river of S. Africa, rises in the Quathlamba (q. v.) Mountains, and after an extremely tortuous course of fully 500 miles unites with the Orange River in 29° 10′ S. lat., 24° 28′ E. long. Its Dutch name of V., and its Hottentot designation of Ky Gariep, both have reference to its yellow colour when in flood. By the Bechuans the V. is called the Namagare or Likwa.

Vaca'tion, in English law, is the time between the end of one term and the beginning of another, which commences the last day of every term as soon as the court rises. There is also a V. in the *spiritualities*, from the death of the bishop or other spiritual person until the appointment of another. The word is also used to denote school-holidays.

Vaccina'tion (from Lat. *vacca*, 'a cow') is the process by which the *materies morbi* of a specific disease, termed *vaccinia*, is introduced into the human organism with the view of protecting the individual against an attack of smallpox. The protective power afforded by V. was discovered by Dr. Jenner, who made his first experiment in 1792, and published his results in 1798. The real date of the introduction of V. into England may be said to be 1796. The results were extraordinary. In the ten years ending 1799, the deaths from small-pox in London were 22,863 to the million; in the ten years ending 1819 they were 8045 to the million; and in the ten years ending 1849 they were only 4798; so that V. may fairly claim to have reduced the mortality from about 23,000 to 5000 in fifty years. Jenner, in his *Inquiry into the Cause and Effects of the Variolæ Vaccinæ*, published in 1798, shows (1) that cow-pox casually communicated to man has the power of rendering him unsusceptible of small-pox; (2) that the specific cow-pox alone, and not other eruptions affecting the cow, which might be confounded with it, has this protective power; (3) that the cow-pox might be communicated at will from the cow to man by the hand of the surgeon, whenever the requisite opportunity existed; and (4) that the cow-pox, once ingrafted on the human subject, might be continued from individual to individual by successive transmissions, conferring on each the same immunity from small-pox as was enjoyed by the one first infected direct from the cow.

The vaccine virus is a colourless, somewhat viscid fluid, consisting mainly of the bioplasm of Beale. On microscopic examination, no definite forms can be detected, but a multitude of minute molecules may be seen. This vaccine is simply the infectious matter of small-pox modified by passing through the body of the cow. The identity of cow-pox and small-pox is certain. Vaccine was originally taken from the cow, but is now taken from the human subject, an uninterrupted series of pocks having been kept up and transmitted by vaccinators. Recently, however, cattle have been inoculated with small-pox, and matter from the resulting cow-pox pustule has been used for V. purposes.

The Operation of V. is performed as follows:—A small quantity, a drop or two, of the vaccine lymph is taken upon the point of a lancet or other instrument, and inserted in four or more points in the skin. On the day of the operation there is usually a little redness around the punctures or scratches; but this soon disappears, and the skin assumes its natural appearance. On the third or fourth day the skin at the spot becomes slightly elevated, hard, and red; on the fifth or sixth day a vesicle of a bluish-white colour, with an elevated edge and a depressed cup, forms; on the eighth day the vesicle reaches its maturity, and is distended with clear lymph; on the ninth day the vesicle is surrounded with an inflamed ring or areola; on the ninth, tenth, and eleventh days the vesicle becomes a pustule, the cupped form disappears, and the areola enlarges till it becomes a circle, with a diameter of from 1 to 3 inches; on the twelfth, thirteenth, and fourteenth days, the pustule dries up; and in the course of the following week the scab separates and falls off. On the appearance of the areola there is usually slight constitutional disturbance, and occasionally swelling of the glands in the armpits; but these symptoms are not often severe, and as a general rule no treatment is required. It is quite immaterial on what part of the body V. is performed, but the usual part selected is on the arm at the insertion of the deltoid muscle. After the separation of the scab, and the healing up of the sore, a cicatrix is left which is permanent in after life. The cicatrix is dotted or indented with minute pits, and is sometimes radiated.

As a general rule children should only be vaccinated when they are in apparently good health, unless when small-pox may be in the neighbourhood. Dr. Seaton, the medical officer of the Local Government Board, says—'Plump and healthy children living in large towns should be vaccinated when a month or six weeks old; in more delicate children the V. might be postponed till they are two or three months old; but all, except those whose state of health positively contra-indicates V., should be vaccinated by the age of three months.'

The lymph used should always be taken from a healthy child, and from thoroughly characteristic vesicles. Dr. Jenner recommended that lymph for V. purposes should be taken from the human subject on the sixth day, the day on which the lymph is most active, though less plentiful. Dr. Seaton says—'Prime lymph has always a certain degree of viscidity; and a thin serous lymph, even from a vesicle which is not advanced, is to be avoided. Babies are much better lymph-givers than older children or adults; and children of dark complexion, not too florid, with a thick, smooth, clear skin, yield the finest and most effective lymph.' V. should always, when practicable, be performed from arm to arm, and preserved lymph should only be used when a vaccinated child cannot be obtained. A good vesicle exudes lymph sufficient for the V. of five or six children.

The extent to which the V. Act is carried out in England and Wales may be gathered from Dr. Seaton's Report to the Local Government Board, 1878. 'Of 850,354 births returned to the Board by the several V. officers in England and Wales, as registered during the year 1875, the number which at the time the return was made had been registered as successfully vaccinated was 722,466 (being 84·9 per cent. of the whole), and the number

registered as having died before they could be vaccinated was 86,673 (or 10·2 per cent. of the whole. Of the remaining 41,215 children, 838 (or 0·09 per cent. of the whole) had been registered as insusceptible of successful V. Of these probably not one was really insusceptible. The cases included under this heading are children who, being certified as having been three times unsuccessfully vaccinated, are no longer subject to the compulsory provisions of the law, 38 (or 0·004 per cent.) had contracted small-pox before they could be vaccinated; 5914 (or 0·69 per cent.) as having their V. postponed by medical certificate, leaving 34,425 (or 4·04 per cent.) as 'removed,' 'not to be traced,' or otherwise unaccounted for. If from the 850,354 births deduction of the deaths without V. be first made, it appears that of the surviving 763,681 children there were registered at the time of the return 94·6 per cent. as successfully vaccinated; 0·11 per cent. as either insusceptible of V., or as having had small-pox; and 0·77 per cent. as under medical certificate of postponement, leaving 4·5 per cent. as at that time still to account for.' From the last returns of the Registrar-General for Scotland, 1874, we learn that 87·213 per cent. were successfully vaccinated; that 0·992 per cent. were postponed; that 0·166 were insusceptible constitutionally; 0·027 from having had small-pox; 0·165 from previous V.; 9·114 died before V.; and 2·323 had removed from the district and could not be traced.

Dr. Jenner supposed that by V. the individual would be infallibly protected against an attack of small-pox during his life, and that by V. alone small-pox would be entirely eradicated; but it has been established beyond a doubt that V. does not adequately protect the individual more than a certain number of years. Re-vaccination is a physiological test by which it may be ascertained whether the individual is liable or not to be attacked with small-pox. If the person is unsusceptible or protected by primary V., re-vaccination will be abortive, or will only produce an irritant effect; but if he is susceptible, the vaccine pock will run its natural course. The exact length of time during which a person is protected by V. probably varies; but every individual should be re-vaccinated at the age of sixteen. Dr. Heim of the Wurtemberg army has collected statistics relative to 40,000 revaccinations. The subjects were young recruits from twenty to twenty-one years of age, who had all been vaccinated in infancy. Of these one-half were successfully re-vaccinated, the vesicles running their normal course; so that these 20,000, although previously vaccinated, were susceptible to small-pox. After the Wurtemberg Government made revaccination compulsory there was a marked decrease of small-pox in the army; thus in 1824 there were 619 cases; in 1835, 250; in 1836, 159; and in 1837, 94. In 1858 an order was issued in Great Britain by which every recruit on joining his regiment was to be revaccinated, and this regulation still continues in force.

Law Regarding V.—The principal Act now in force regarding V. is the 30th and 31st Vict. c. 84, which contains the penalties for the breach of its enactments, and provides (sec. 33) for the costs of prosecutions, while sec. 38 provides for the expenses incurred in certain other proceedings in respect of V. The Act has been amended by 34 and 35 Vict. c. 98. In England the V. of all children three months of age and under is compulsory; but in Scotland the age is six months and under.

Vaccinia'ceæ, a sub-order of *Ericaceæ*, differing from *Ericeæ* in having epigynous stamens and an inferior ovary. *Vaccinium* and *Oxycoccos* are the best-known genera (see WHORTLEBERRY and CRANBERRY). About 15 genera range under V., consisting of much-branched shrubs or small trees, with simple, often evergreen leaves, and frequently richly-coloured flowers. They are fairly represented as garden plants.

Vac'uum (Lat. 'empty'), in physics, denotes a portion of space void of matter. The possibility of the existence of a perfect V. has been a favourite subject of discussion among metaphysicians; and that the negative view was popular is indicated by the historical phrase 'the vacuum which nature abhors.' Descartes asserted that if the contents of a hollow vessel were taken out without anything entering to fill its place, the sides of the vessel would be in contact. This assertion, however, is based upon the dogma that the only essential property of matter was its extension; that, in other words, matter was indistinguishable from space. Such inquiries, however, can lead to nothing definite. The experimental philosopher is obliged to recognise the practical impossibility of obtaining a perfect V. The so-called Torricellian V., which exists above the mercury column of a barometer, is really filled with mercury vapour probably mixed with a small percentage of air. The very action by means of which the air-pump produces its V. shows that there can never be an absolute void—a little air always remaining behind. Andrews, following up a suggestion of Davy, has obtained remarkable vacua by first pumping in carbonic acid so as to expel as far as possible the air, and then after ordinary exhaustion leaving the carbonic acid to be taken up by moistened caustic potash which has been previously placed in the receiver. In this way Andrews has removed all but $\frac{1}{350.000}$th of the gas originally present, whereas by ordinary air-pump action only $\frac{1}{120}$th of the gas can be removed. Frankland, Gassiot, Crookes, Dewar, and others, have devised various improvements. Dewar takes advantage of the property of gases to condense on the surface of solids in a remarkably ingenious way. A piece of carbon, placed in the V. vessel, is kept heated while the vessel is being exhausted. After the exhaustion is completed as far as possible, the carbon is allowed to cool so as to permit the small quantity of gas present to condense in its pores. A gentle heating of the carbon at once releases a quantity of the gas, so that this method is invaluable in the study of electric discharges through rarefied gases, since the rarefaction can be so easily altered at will.

Va'grancy. See BEGGAR, and POOR and POOR LAWS.

Vagi'na, the membranous canal leading from the *uterus* or Womb (q. v.) to the external genitalia. The V. in lower mammals, such as the *Ornithorhynchus*, opens into a *cloaca* (see ORNITHODELPHIA), while in the kangaroos and other *Marsupialia* (q. v.) it opens into a canal named the *uro-genital canal*, which receives the efferent ducts of the urinary organs. In higher quadrupeds the V. is distinct both from the *rectum* and the urinary ducts. In the human subject it attains a length of about 4 inches measured along its anterior wall and 6 inches measured on its posterior surface. It lies between the bladder and rectum; constricted at its commencement it becomes dilated towards its uterine end. The coats of the V. number three—an external or muscular layer, a layer of erectile tissue, and an inner or mucous layer. The mucous layer is thrown into folds or *rugæ*, which permit the distension of the canal in the process of *parturition*.

Vaigatch', an island in the Arctic Ocean, 67 miles long by 26 miles broad, belonging to the Russian government of Archangel, separated by the V. or Yugor Strait from the Continent, and by the Kara Strait from Novaia Zemlia. Its northmost point is under lat. 70° 29' W. V. is mountainous, especially in the middle. The vegetation is very poor; only on the southern declivities of the mountains are found the sorrel, wild onion, spoonwort, and forget-me-not. V. is rich in furred animals (red and blue foxes, reindeer, polar bears, and wolves), sea-birds, and sea-animals; and in summer the few Samoyedes who live permanently on V. are visited by bands of Russian, Syryane, and Samoyede hunters.

Vaillant, Jean-Baptiste, Philibert, Comte, a French marshal, was born at Dijon, December 6, 1790, and after studying at the École polytechnique entered the army in 1809 as sub-lieutenant of engineers. He accompanied the grand army in the Russian expedition, and had the misfortune to be taken prisoner. From 1826 to 1830 he served as chief of a battalion in Algiers, and in 1832 he distinguished himself at the siege of Antwerp. In 1837 he returned to Algiers to superintend the fortifications, and in 1840 the reconstruction of the fortifications of Paris was entrusted to him along with Marshal Dode de la Brunerie. His last important achievement was the siege of Rome in 1849, which led to his receiving the marshal's baton in 1851. In 1854 he was War Minister. V. died at Paris, June 4, 1872.

Vaish'nav or **Boish'tob**, the name of that Hindu sect which pays especial worship to Vishnu (q. v.) above the other two members of the trinity. No less than six historical subdivisions are enumerated, founded by successive religious reformers, in protest against the corruptions of Brahminism. The chief places of pilgrimage are Juggernauth, Brindabun, Benares, and Seringam. The sect generally may be divided into two divisions —the devotees, who are either *gosains* or *gurus*, of whom many

live in convents and profess celibacy; and the lay members, who largely belong to the well-to-do and trading classes. The general census, 1868-1872, returns only 540,000 Vaishnavs throughout all India, chiefly in Lower Bengal; but this only includes the Byragees or ascetics, and presumably not all even of them. The Madras Census Report of 1871 states that 11,657,000 persons in that Presidency, or 40 per cent. of the total Hindu population, chiefly in the N.E., are Vaishnavs. See *Sketch of the Religious Sects of the Hindus*, by H. H. Wilson (Works, vol. i. Lond. 1862).

Val'ais (Ger. *Wallis*), the third in size of the Swiss Cantons, is bounded N. by Lake Geneva, Vaud, and Bern, E. by Uri and Ticino, S. by Italy, and W. by France. Area, 2025 sq. miles; pop. (1877) 101,131, nearly all Catholics. Forming the valley of the Upper Rhone from its source to its entrance into Lake Geneva, and enclosed by the Bernese and the Pennine Alps (q. v.), V. is mainly devoted to the rearing of cattle, sheep, and goats, only a fourth of the surface being arable. Cheese-making, bee-keeping, and the cultivation of the vine, are also sources of considerable wealth. V. is one of the two mining cantons, yielding iron, lead, cobalt, nickel, sulphur, and anthracite; but its manufactures (silk, cloth, glass, &c.) are unimportant. Of Celtic origin, the inhabitants of V. were reduced by Cæsar to the sway of Rome, and were under Burgundians, Franks, and others for several centuries. In 1032 the territory of V. became an imperial fief, and as such was held by the Dukes of Zähringen, whose cruelty led to an insurrection (1184-1211). In 1477 V. formed an alliance with Bern, and in 1597 entered the Swiss Confederacy. See Furrer's *Geschichte von Wallis* (1874).

Valck'naer, Ludwig Kaspar, a Dutch philologist, was born at Leeuwarden in Friesland, 7th June 1715. In 1741 he succeeded the famous Hemsterhuis in the Greek chair at Franeker, and in 1766 was called to Leyden, where he died 15th March 1785. During his lifetime he published *De Ritibus in Jurando* (Franek. 1735), and edited Theocritus and some of the plays of Euripides; and after his death his *Observationes Academicæ* were brought out by Scheidius (Utrecht 1790), his edition of *Callimachi Fragmenta* by his son-in-law Luzac (Leyden 1799), and two volumes of *Opuscula* by Erfurdt (Leip. 1808). His letters to Ernesti were edited, along with those of Ruhnken by Tittmann (Leip. 1802), and his erudite treatise *De Aristobulo Judæo* appeared in 1806. V. was an admirable scholar. To an exact and critical knowledge of the classical languages he added an equally critical knowledge of the antiquities of Greece and Rome. No man worked harder or to better purpose in the cause of humanistic learning. See Bergmann, *Memoria L. C. Valckenarii* (Utrecht 1874).

Valdai' Hills or **Volshon'ski Forest**, the highest elevation in the interior of W. Russia, forming the watershed between the Volga and the feeders of Lake Ilmen, and containing the sources of the Volga, the Dnieper, and the Düna, lie on the borders of the governments of Novgorod and Tver. They consist of wooded ranges averaging 295 feet in height, though rising in Popova Gora to 1080 feet, rich in sandstone, lime, and black and red clay.

Valdepe'ñas, a town of Spain, province of Ciudad Real, 32 miles S.E. of the city of Ciudad Real. Its celebrity depends wholly on the red wine of V., which is highly esteemed by connoisseurs, but can seldom be obtained pure out of Spain. Pop. (1860) 7400.

Valdiv'ia, a town in the S. of Chili, capital of a province of the same name, on the river V., 9 miles from its mouth, with a safe and roomy harbour. The entrance to the river is fortified. The town is built on level ground, and is embosomed in apple orchards, surrounded by the native forest. It has an active coasting trade, chiefly with Valparaiso. V. was founded in 1551 by Pedro de V., one of Pizarro's lieutenants, who named it after himself, and it was at one time a place of great wealth. At the census of 1875, however, the pop. was only 3872. The *province* of V. has an area of 10,715 sq. miles, with a pop. in 1877 of 31,826. Besides splendid forests it has large upland pastures, and deposits of coal are known to exist within it.

Valence', capital of the department of Drôme, France, on the left bank of the Rhone, 65 miles S. of Lyon by rail. It is an old walled city divided into a high and low town. It has an ancient citadel, and a cathedral of Saint Apollinaire, in the pure Romanesque style, dates in its present form from the 11th c. The Protestant Collegiate church of St. Ruf and several others are of architectural interest. On a steep hill opposite the town stand the picturesque ruins of the castle of Creussol. V. has a good museum, a public library, a botanic garden, and an artillery school, where Napoleon studied 1785–91. There are a few Roman remains in the neighbourhood, especially at a little place called Die. Silk, olive-oil, leather, glass, gloves, cotton goods, wines, and spirits are manufactured and exported in considerable quantity. Pop. (1876) 23,220. Some say V. was founded by the emperor Valens; others identify it with *Valentia Segovellanorum*, a military station in Cæsar's time. The Protestant party were strong here at the time of the Reformation, and fierce struggles took place between them and the Catholics.

Valen'cia, a town of Venezuela, situated in a very rich district two miles W. of a lake of the same name, and 30 miles S. of Puerto Cabello (q. v.), with which it has a brisk trade. Large numbers of cattle, horses, and mules are reared in the neighbourhood. Pop. (1875) 28,594. The lake of V. measures about 54 miles by 14, but is decreasing in size, though it receives a number of large streams and has no outlet. A great many fertile islands stud its surface.

Valen'cia, a former kingdom of Spain (now forming the three provinces of V., Alicante, and Castellon de la Plana) which was bounded N. by Aragon, N.E. by Catalonia, W. by Murcia, New Castile, and Aragon, and E. and S.E. by the Mediterranean Sea. Area 8897 sq. miles; pop. (1871) 1,393,660. The surface is in great part mountainous, and is abundantly watered by the Guadalaviar (Turia), which crosses it from N.W. to S.E., the Mijares, the Jucar, and the Segura. The soil is exceptionally fertile, and is capable of yielding from three to five crops of various fruits, while the climate is mild and healthy: the heat is tempered by the sea-breezes, and the skies are almost always clear and blue. Hemp, flax, wheat, barley, maize, rice, figs, and almonds are extensively grown, and oranges, raisins, and wine are largely exported. The mineral wealth consists of coal, iron, copper, lead, cinnabar, cobalt, and salt; while the industries are silk, linen, and woollen spinning and weaving, paper-making, and the plaiting of esparto grass. The inhabitants still show unmistakable evidence of their Moorish origin.—**V.**, capital of the preceding, and one of the finest and busiest cities of Spain, stands in a fertile Huerta, on the left bank of the Guadalaviar or Turia, 2½ miles from Villa Grao at its mouth, 170¾ miles S.E. of Tarragona by rail. It is surrounded with old walls and ramparts with four towers, has three suburbs, many promenades—the finest the Glorieta—and five fine bridges over the river. Its streets are narrow and crooked, most of them unpaved, and it has many old public and private buildings in the Moorish style of architecture. It has 17 chapels, 13 convents, 14 former monasteries, and 14 churches, of which the principal are the chapel De Los Desamparados, the churches San Juan, San Martin, San Andros, San Esteban, and the famous Cathedral, an irregular but imposing building with an octagonal Moorish steeple, El Miguelete, 130 feet high. Other buildings are the palace of the viceroy; the Lonja, in the Moorish-Gothic style, with an imposing piazza, a great mart for raw silk; the Casa Consistoriates or Town-hall; the Serrano Gate; and the Gothic Longa de Seda. V. is the seat of the Governor of V. and Murcia and of an archbishop, and has a theatre, an academy of fine art, a picture-gallery (*museo*) containing fine examples of Juanez, a house of correction (*presidio modelo*), a university (founded 1410) with a library of 56,000 vols. and the best botanic garden in Spain. The principal industry of V. is silk spinning and weaving; it has, however, large manufactures of azulejo porcelain, and of tobacco, the royal factory alone giving employment to 3200 women and 250 men. It is the seat of an extensive trade in oranges and wine. In 1873 there entered and cleared the port 3879 vessels of 629,680 tons, and the total imports amounted to £1,420,000, the exports to £876,000; while in 1877, in 68 British vessels the importations amounted to £196,122, and consisted of 30,878 cwts. of codfish, 24,875 tons of coal and patent fuel, 105 tons of oil, 1013 tons of iron, 805 tons of rails, 30 tons of machinery, 35,674 sleepers, and 12,100 tons of Peruvian guano, the value of the last article alone being estimated at £145,000. In the same year the exports

in British vessels amounted to £473,450, and consisted of onions, oil, saffron, silk, staves, melons, raisins, minerals, wine, and oranges, the last alone computed at £420,000. Pop. (1877) 153,500. V. was destroyed by Pompey and rebuilt by Sertorius, and fell at the end of the 5th c. to the West Goths, and in 715 to the Moors. In 1094 it was taken by the Cid, but after his death was recovered by the Moors, from whom it was taken by Jago I. of Arragon in 1238, and united finally to that kingdom in 1319. Subsequently to 1609 it declined from the expulsion of the Moriscoes, in 1706 it declared for Carlos III., and in the Peninsular War held out bravely against the French. In 1835 a revolutionary junta here declared against Queen Isabella; and here, in 1840, Queen Christina abdicated her regency. In 1852 it was the locality of a fruitless Carlist plot.

Valenciennes, an important manufacturing town of France, in the Department du Nord, on the borders of France and Belgium at the junction of the Rouelle and Scheldt, and is connected by rail with Paris, Amiens, and Lille. The fortifications and citadel constructed by Vauban still stand; the town contains also an art gallery and museum, a gymnasium, and other higher schools, and a library of 25,000 vols. and over 800 MSS. Besides the trade which accrues to it as the custom-house station between France and Belgium, V. has extensive foundries, distilleries, flax mills, sugar-refineries, &c. Its lace has long been celebrated. Pop. (1876) 26,083. V. appears in the earliest times of the Frankish empire as *Valentia*, and in the 11th c. its favourable situation made it the chief city of Hennegau, and, while it belonged to Flanders, a favourite residence of the Flemish counts. In 1677 it was taken by Louis XIV.

Val'ens, Fla'vius, Roman Emperor in the East, was born in Pannonia about 328, and was invested with imperial authority by his brother Valentinianus, who reserved for himself the government of the West. The principal events that distinguished the reign of V. were (1) the revolt of Procopius, who was accepted as Emperor by the people of Constantinople during the absence of V., but was defeated and executed (366); (2) the Gothic war, which lasted during the whole of V.'s reign. At first the Emperor was successful, and concluded an honourable peace with the barbarians (370). Six years later the Goths, pressed southward by the Huns, asked and obtained permission to settle within the empire. Lands were allotted to them S. of the Danube, and under wise management they might have become a powerful bulwark of the empire; but incited to revolt by the treatment they received at the hands of the imperial officials, they took up arms. In 378 they defeated V., and destroyed two-thirds of his army. The Emperor himself was never seen after the battle, and we have no certain information as to the manner of his death. During this reign the controversies between the Catholics and Arians were of an extremely bitter character. V. was himself an Arian; and through his influence this form of faith became widely spread in the East, and was adopted by the Goths. See Gibbon, chapters xxv. xxvi., and Tillemont's *Histoire des Empereurs*, vol. v.

Valen'tia (called by the people of Munster *Darrery*, from a famous 'Druid' prince, Dairbhre, who had his seat here), an island on the S.W. coast of Ireland, belonging to County Kerry, from which it is separated by a narrow channel opening into V. Bay. Area 6371 acres; pop. (1871) 2139. The harbour on the N. side of the island is the most western in Ireland, and from it two telegraph cables extend to Newfoundland, one laid in 1865, the other in 1866.

Val'entine, Bas'il, an eminent alchemist who flourished about the 15th c., and was probably a monk. So little is known of him, however, that it has been conjectured that the name is an assumed one. He wrote many works with quaint titles on alchemy and medicine, and these show him to have been an acute observer and able experimenter. He gave much of his attention to medicine, 'was the first who counselled the internal use of antimony, and recommended preparations of mercury for syphilis,' then believed to be a new disease. His works, written in the old Upper Saxon dialect, are said to have been concealed inside a column at the abbey of Erfurt. A stroke of lightning broke the pillar and disclosed the treasure, which was first printed in 1602. See Lenglet, *History of the Hermetic Philosophy*, vol. iii.; Hœfer, *Histoire de la Chemie*, vol. i.

Val'entine's Day falls on the 14th of February in each year, and is now commemorated in Britain and some parts of the Continent by a custom among young persons of both sexes of exchanging sentimental or ludicrous *souvenirs*. The saint whose name is attached to the day has nothing in the history of his life to justify this custom. He was a priest who assisted the Christians during the persecution under Claudius II., for which he was seized and put to a most painful death, being first beaten with clubs and then beheaded (about 270). A church was built to his honour at Rome by Pope Julian, and in that city his relics were collected and preserved, while his name was taken to Christianise an old festival of his murderers. V.'s D. is probably a continuance of the feast in honour of Pan and Juno, called the Lupercalia, and annually held in Pagan Rome with all sorts of obscene rioting about the middle of February. Long after the introduction of Christianity the feast continued to be observed, and as the clergy could not destroy the custom, they resolved to adopt it, and placed it under the patronage of the saint of the day. Some centuries ago it was the custom in our island for a number of a young people to write each a name, place the papers in a box, and drawing from thence to obtain a 'Valentine.' The chosen party gave a present to his or her chooser; and in the case of persons of high rank these presents were often very valuable. It was supposed that the birds mated on this day, and this no doubt gave rise to the Valentine customs. Perhaps, too, the feast might be taken to indicate human joy in the prospect of reviving nature. In many of the English poets—Chaucer, Lydgate, Shakespeare, Drayton, Donne, and others—and in a number of popular ballads, we find allusions to the customs of this day.

Valentin'ians, a Gnostic sect founded by Valentinus, probably a Jew, who came from Rome about 140. His system of theology was briefly as follows:—From the great Original (*Bythos, Propator, Proarche*) emanate male and female *æons* (manifestations of him who is incomprehensible) in pairs, to the number of thirty; who together form the Pleroma. From the passionate striving of the last æon, Sophia, to unite with Bythos, arises an untimely being, Achamoth, who communicates the germ of life to matter (thereby producing disharmony in the Pleroma, by mixing the divine element with matter), and forms out of *psychical* matter the Demiurge, who in turn immediately creates the world. The existence of all created beings depends on *limitation*; and to Horus, the genius of limitation, two operations belong—a *negative* one, by virtue of which he separates the godlike from the ungodlike; and the *positive*, by which he establishes in their own peculiar essence those who are purified from the foreign elements by which that essence had been disturbed. It was this Horus or Saviour who was united with the man Jesus, the Messiah who had been provided by the Demiurge.

Valentinia'nus, the name of three Roman Emperors.—**V. I.** was born in Pannonia in 321, entered the military service, filled various important posts, and on the death of Jovian in 364 was raised to the purple by the troops at Nicæa. He assumed the government only of the Western part of the empire, and assigned the East to his brother Valens. His whole reign was one long struggle against the encroachments of the barbarians, who from so many quarters were attacking the empire. His endeavours were attended with a considerable measure of success. He defeated the Alemanni, strengthened by fortresses the Rhine frontier, and even made successful incursions into the territory of the enemy. V. was a Catholic, but he molested neither Arians nor heathens, and showed himself rather anxious to improve and defend his vast dominions than to engage in the theological strifes of the period. He died suddenly, November 13, 375, when on an expedition against the Quadi and Sarmatians. —**V. II.**, son of the preceding, who had been proclaimed emperor by the army, was but four years old at the time of his accession. He only succeeded to Italy, Illyricum, and Africa, as his elder brother Gratian retained Gaul, Spain, and Britain. In 387 V. was driven from Italy by Maximus, who had slain Gratian; but next year he was restored, and invested with the government of the empire in the West by Theodosius, then emperor in the East. On May 15, 392, V. was murdered by Arbogastes, a Roman general of Frankish origin, whom he had incensed by attempting to deprive of his command.—**V. III.**, Emperor in the West, was the grandnephew of the preceding and the son of Constantius III. He was born about 419,

and succeeding to the throne when only six years of age, the real power was for long held by his mother Placidia. The Vandals, the Goths, and the Huns (under Alaric) made fearful inroads into the empire during this reign, and the first of these took possession of Africa, which they held for a century. The empire was bravely and skilfully defended by the experienced general Aëtius, but during a quarrel with the emperor the latter drew his sword and slew his able commander (454). Next year V. was assassinated by Petronius Maximus, who thus avenged the violation of his wife's honour by the emperor. See Gibbon's *Decline and Fall*, chap. 25, *et seq.*; Tillemont's *Histoire des Empereurs*, vols. 5 and 6; and Siever's *Studien zur Geschichte der Römischen Kaiserzeit* (Berl. 1870).

Valen'za, a town of N. Italy, province of Alessandria, on the right bank of the Po, 9 miles N.E. of Alessandria by rail. Its cathedral is of the 16th c. V. has some manufactures and a trade in wine. Anciently a town of the Liguri, it was taken by Marcus Fulvius, who named it *Forum Fulvii, quod Valentinum*. After a siege of ninety days, it was taken by the armies of France, Savoy, and Parma in 1635, and its fortifications were razed by the French in 1805. Pop. (1874) 9835.

Vale'rian (*Valeriana*) is the type genus of *Valerianaceæ*, an order of herbs or rarely shrubs belonging to the division of monopetalous dicotyledons having the stamens arising from the petals. The order is distinguished from its congeners by the opposite leaves; small irregular flowers in which the corolla lobes are imbricate; stamens, one to three or five, free; ovary one to three celled, one cell one-ovuled; ovule pendulous; seeds exalbuminous. It contains 12 genera and about 190 species, distributed through Europe, N. Africa, temperate Asia, and N.-W. America—unknown in Australia, and only one species S. African. The properties are aromatic, antispasmodic, sometimes stimulant. The genus *Valeriana* numbers 130 species. Of these, *V. officinalis*, ranging across N. and Central Europe and Asia to Japan, is a common British plant. Its rootstock has long been valued as an antispasmodic, and is successfully employed in hysteria. It has a penetrating odour, and a bitter, acrid, somewhat aromatic taste; when distilled with water it yields a volatile oil and Valerianic Acid (q. v.). Cats have a strange liking for the odour, and it exercises a remarkable intoxicating or stimulating power over them; the plant is sometimes called Cats' V. The roots of *V. celtica* are used by Eastern nations as a substitute for spikenard for aromatising their baths, and those of *V. edulis* as an article of food by the Indians of N.W. America. The Red V. (*V. pyrenaica*), a native of S. France and Spain, has become naturalised in parts of Britain, and several other species are commonly grown in gardens. The word V. is from Latin *valere*, 'to heal,' and one of the names of *V. officinalis* is 'all-heal.'

V. officinalis.

Valerianell'a. See CORN SALAD.

Valeria'nus, Pub'lius Licinius, a Roman emperor of a noble family, born about 193 A.D., entered the service of the state, filled several important posts, and on the murder of the Emperor Gallus and the sudden death of his rival Æmilianus, was elected emperor (253) in 'right of his merits, and by the unanimous voice of the whole world.' V. spent his reign in repelling the attacks of the barbarian hordes who were attacking the empire on all sides. He defeated the Goths (257), and waged war in person and for some time successfully against the Persians, who had overrun Syria, but was finally captured by the enemy at Edessa (260), and spent the rest of his life in captivity. On his death his barbarous foes stuffed his skin and preserved it as a trophy. In more peaceful and prosperous times V. would have been classed among the 'good emperors.' Hard fate ranks him only among the 'unfortunates.' See Gibbon's *Decline and Fall*, chap. x.

Valer'ic, or Valerian'ic Acid ($C_5H_{10}O_2$), an organic acid present in valerian root, angelica root, in the berries of *Viburnum opulus*, and probably in many other plants. It is prepared artificially by oxydation of ordinary amyl alcohol ($C_5H_{12}O$), two atoms of hydrogen being removed and one of oxygen added. The most advantageous method of effecting the oxidation is to treat the amyl alcohol with a mixture of sulphuric acid and potassium dichromate. After a series of operations the V. A. separates as an oily liquid lighter than water and having the composition $C_5H_{10}O_2H_2O$. The water is driven off by distillation, and the pure acid obtained as a mobile colourless oil. It has a sharp acid taste, reddens litunes, and burns with a bright but smoky light. It has a density of ·937, and boils at 175°. It forms valeriates with metallic oxides, but its compounds are not of much importance. Ethyl valerate ($C_2H_5C_5H_9O_2$) is formed by passing hydrochloric acid gas into an alcoholic solution of V. A.

Vale'rius Max'imus, a Roman historian, wrote between 29 and 32 A.D. the extant *Factorum Dictorumque Memorabilium libri ix. ad Tiberium Cæsarem Augustum*, a large collection of historical anecdotes arranged under miscellaneous heads. The style of V. M. is forced and cumbrous; 'his Latinity,' said Erasmus, 'is no more like Cicero's than a mule is like a man.' Of this work we also possess two abridgments, by Julius Paris and by Januarius Nepotianus, published by Mai in 1828. The *editio princeps* of V. M. is by J. Mentelin of Strassburg, 1470. The best editions are by Aldus Manutius (Ven. 1534), Lipsius (Antw. 1585), Kempf (Berl. 1854), and C. Halm (Leip. 1865).

Valett'a, the capital of Malta, and a strong fortress, beautifully situated on the N. side of the island on a promontory with deep bays on either side. The harbour on the S.E. side is rendered nearly impregnable by the Fort of St. Elmo and other batteries. V. has a vast fortification garrisoned by some 3000 men, and is the station of several war vessels. Its harbour, which has a depth of 50 feet, is one of the best in the Mediterranean, and from the quay the streets ascend precipitously, in many places rising in long flights of steps. The buildings comprise a richly decorated cathedral of S. Giovanni (1576), which contains monuments of grand-masters and knights of Malta, the governor's palace, with collections of weapons, trophies, &c., and a library of 60,000 vols. V. is supplied with water by an aqueduct begun in 1610, and has a botanic garden and ramparts adorned with many statues of grand-masters and English governors. On the E. side of the harbour lies Borgo or Citta Vittoriosa, the older part of the town, and farther distant Burmula or Citta Cospicua with its new docks. V. is the chief trading port of Malta and an important naval station on the route to Egypt and India. Pop. 70,000. V. was founded by and named after the Grand-master Valette in 1566.

Valette', Jean Parisot de la, born of a noble family at Toulouse, France, in 1494, entered the Order of the Knights of St. John (q. v.), and on the 21st August 1557 was elected its grandmaster. Within five years he captured 50 great Turkish galleys and a great number of smaller vessels, thereby provoking the Sultan to attempt the annihilation of the Order. With 159 war-ships and 30,000 select troops the Turks began their famous siege of Malta on the 18th May 1565. The fortifications were defended by 8500 men, with but 700 knights (not including 'serving brothers'), but with these V. fought heroically till the 8th September, when the viceroy of Naples came to reinforce the gallant garrison, now dwindled to 600 souls. After another vain attack the besiegers finally withdrew. On the 28th March 1568, V. laid the first stone of the town of Valetta (q. v.), which, with its suburb *Vittoriosa*, commemorates his name and memorable victory, and where V. died on the 21st August of the same year. See Vertot, *Histoire des Chevaliers de Malte*; De Thou, *Historia sui Temporis*; and Porter, *Knights of Malta* (vol. ii.).

Val'gus is a term employed in surgery to designate a variety of Club-foot (q. v.).

Valhall'a (Old Norse *Valhöll*, from *val-r*, 'corpses,' and *höll*, 'hall,' *cf.* O. H. G. *halla*), in Northern Mythology (q. v.), the chief hall in Asgard, the banqueting-house of the Æsir (q. v.), there entertained by Odin along with the *Valr* or

Einherjar chosen by the Valkyrjur (q. v.).. V. has 540 doors, through each of which 800 Einherjar may pass abreast. In front is the grove Glasir, whose leaves are golden. West of the door is a great wolf, and overhead a crouching eagle. Gleaming swords light up the hall. The roof-trees are spears, the roof itself is formed of shields, and the seats are covered with shirts of mail. The Einherjar eat the flesh of the boar Sæhrímnir, which is cooked every day, and at night is restored whole as before; and drink mead, which flows from the udder of the goat Heidrun. Every day the Einherjar, as soon as dressed, array themselves in armour, and fare forth into the fields to fight and fell one another. This is their pastime; as it draws to breakfast-time they ride back to V., where they sit down to feast. After Odin's V. is named the Walhalla or Temple of Fame built by King Ludwig I. of Bayern at Donaustauf, near Regensburg (q. v.).

Valkyr'jur [from Old Norse *val-r* (Old High Ger. *wal*), 'corpses,' and *kjora* (Dan. *kaare*, Ger. *küren*), 'choose'], in Northern Mythology (q. v.) are the beautiful 'maids of Odin,' goddesses of fate allied to the Norns. They numbered either nine or thrice nine, and in three bands went forth on horseback and clad in full armour, through air and water, over the wide world to *choose* for Odin the *Valr* or *Einherjar* ('single champions') worthy of Valhalla (q. v.). At home in Valhalla the V. were the cupbearers of the Æsir (q. v.) and the Einherjar. The belief in the V. toward the close of the heathen period may be seen in the *Njalsaga's* description of Daurrud's vision on the day of the battle of Clontarf (q. v.). Twelve women came riding through the air and entered a hillside. Through an opening Daurrud saw them there weave a web of men's entrails, with a sword for batten and arrows for shuttles. They sang the while a song: 'The web, the web of war is weaving for the fight: bloody shall be the fray; a king shall conquer: a mighty king and great chieftains shall be slain.' Another moment, and the web was slit in two. With one-half six of the V. hurried to the N. and vanished, while six sped southward with the other half. The incident has been finely told by the poet Gray in his ode, *The Fatal Sisters*.

Vall'a, Lorenzo della, born at Rome in 1407, studied Greek and Latin under the leading masters, and having failed to succeed to an uncle's post of apostolic secretary, took orders (1431), and accepted the chair of Latin eloquence at Pavia. About this time his *De Elegantiæ Latinæ Linguæ Lib. VI.* (Rome 1471) established V. as the supreme authority on Latin style; and having lectured successively at Milan, Genoa, and Florence, he received from Alfonso V. of Naples a private secretaryship along with the poet's crown (1437). The feud between Rome and Aragon made Alfonso glad to secure so fierce an opponent of the papal see as V., who in *De Falso Credita et Ementita Constantini Donatione* (1440) assailed pope and cardinals, and demolished a lie imposed upon Christendom for centuries. The storm excited by this treatise drove V. awhile to Barcelona, but returning to Naples he continued his assaults, impeaching the Vulgate's Latinity, the authenticity of the Apostles' Creed, and of Christ's letter to Abgarus; and when cited before the Inquisition, declaring the Church knew nothing yet he believed with her. Pope Nicholas V., however, succeeding Eugenius in 1447, summoned V. to Rome, and made him secretary; and he passed his remaining years in translating from the Greek, and in furious literary feuds with Poggio, Trapezuntios, and others among his compeers. He died at Naples, 1st August 1457, leaving behind him Latin translations of Herodotus, Thucydides, and the *Iliad*, *Annotationes in Novum Testamentum* (ed. by Erasmus, Par. 1505), &c., collected in the Basel edition (1543) of his works, and by Vahlen (Vien. 1869). See J. Vahlen's *Lorenzo V.* (Berl. 1870); and chap. v. of Symonds' *Renaissance in Italy: The Revival of Learning* (Lond. 1877).

Vallabhácharya, a Hindu reformer of the 15th c., whose followers form a most influential sect in Western and Central India at the present day. He is regarded as an incarnation of Vishnu; and his descendants, under the title of Maharajah or Gosain, are still treated with semi-divine honours. His system inculcates the worship of Vishnu by his name of Krishna (q. v.), in which form the god sported with the milkmaids; and it leads to self-indulgent and corrupt practices. A Puritan reaction within the sect was started by Swami-Narayan at the beginning of this century. See *History of the Sect of Maharajahs or Vallabhacharyas in Western India* by Karsandas Mulji (Lond. 1865), and Monier Williams' *Hinduism* (1877).

Valladolid', a city of Spain, in Old Castile, capital of the province of the same name, is situated on the left bank of the Pisuerga, and on the Irun-Madrid railway, 102 miles N.W. of Madrid. It is a fortress of the first rank and the seat of an archbishop, has a cathedral founded in 1585 by Philip II., many monasteries, a celebrated university founded in 1346, an institute, an Academy of Fine Arts, a museum containing many beautiful pictures and sculptures, a library, various seminaries and industrial schools, a theatre, hospitals, poor-house, &c. Of its 'plaze' the most beautiful are the quadrangular Plaza Mayor, the octagonal El Ochavo, and above all the triangular Campo Grande, where bull-fights, autos-da-fé, and other public spectacles, used to be held, and where Napoleon is said to have reviewed not fewer than 35,000 men. The manufactures of V., which have recently much revived, are chiefly of cloth, iron, and leather. Pop. (1870) 39,326. The old Roman town of Pintia is said to have been rebuilt in 625 by the Goths, but the name V. was first applied to it after its recovery from the Moors about 1072. From this time till Karl V. transferred the court to Madrid, V. was a favourite residence of the Kings of Leon. It was the birthplace of Philip II.

Valladolid', a town of Yucatan in Mexico. Pop. 10,000.

Valle'jo, a city and seaport of California, on an arm of San Pablo Bay, and on the California Pacific Railway. It has a spacious harbour, a street railway, and several flour-mills, ship-yards, iron-foundries, machine-shops, and broom-factories. V. exports large quantities of grain, and supports six churches and one weekly and two daily newspapers. Pop. (1870) 6391.

Vall'eys, the general name under which all surface depressions flanked by rising-ground are included, are as a rule the result of denudation directed in great measure by the heterogenity of the earth's crust. The countless rills, streams, and rivers which are among the great agents in effecting this wearing action, are the more effectual in their erroding work the softer the material through which their channel for the time being is directed. Hence the harder portions of the earth's crust not being affected so easily are left as hills and mountains, while the softer portions are worn away, and valleys are the result. The scooping action of glaciers must not be overlooked; but it is doubtful whether glaciers could *begin* the formation of a valley as effectually as running water. Volcanic action no doubt has in many cases primarily determined the surface configuration, which has then been intensified in its characteristics by denuding influences; but the theory that in general V. have been wholly or in great part the result of denudation is supported by one of the marked peculiarities of valley structure, namely, that V. meet at an acute angle pointing down their course, exactly as rivers naturally do. Geologically, V. are of great importance, as affording natural sections of the formations which compose the earth's crust at any place. Many facts bearing upon the nature and formation of V. are noticed under MOUNTAINS, RIVERS, GLACIERS, &c.

Vallisne'ria, a genus of freshwater plants belonging to *Hydrocharidaceæ*, consisting of two species, of which *V. spiralis*, occurring in S. Europe, and widely spread over temperate and tropical regions of the world, is a favourite plant for aquaria. The long, narrow, grass-like leaves, from their tenuity and transparency, show in a most instructive manner, under the microscope, the movement of the cell contents; and the mode of fertilisation in this plant is highly curious. Male and female flowers are borne on different individuals; the former become detached, and rise and float on the surface of the water, to which level they are followed by the female, borne on a long spirally-twisted peduncle or stalk. After fecundation, the peduncle contracts and brings the ovary down to the bottom to mature.

Vallombro'sa (Ital. 'shady vale'), a Tuscan abbey, seated in a secluded valley of the Apennines, some 24 miles E.S.E. of Florence, and 2980 feet above the sea. Founded by St. Giovanni Gualberto, Lord of Pistoja, about 1058, for monks of the Benedictine Order, the abbey received many rich endowments, out of which was reared the present spacious and stately pile (1673). Since the suppression of monasteries in 1869, the greater part has been converted into an *Instituto Forestale*

('school of forestry'), but two monks still (February 1879) linger in the 'convent' as a memorial of the vanished Past. Milton's mention of V. in *Paradise Lost* has made the name familiar to Englishmen—

> 'Thick as autumnal leaves that strew the brooks
> In Vallombrosa, where the Etrurian shades
> High overarch't imbowr.'

Valls, a town of Spain, province of Tarragona, on the Francoli, 8 miles N. by E. of Reus by rail. It has extensive manufactures of paper, brandy, cottons, linens, leather, soap, &c. Pop. 16,500. The French gained a victory here over the Spaniards, 25th February 1809.

Val'my, a village of France, department of Marne, 20 miles N.E. of Châlons, is celebrated for the repulse of the Prussians under the Duke of Brunswick by Kellerman, 20th September 1792. This, the first victory of the Republicans, had an important influence on the subsequent course of the war, by the confidence with which it inspired the nation in their troops and generals.

Val'ois, a former county, then duchy of France, included now in the departments Oise and Aisne. The last survivor of the ancient counts, who belonged to a younger branch of the house of Vermandois, married Hugo, the son of Henri I., and brought as her dower V. and Vermandois. Out of this marriage sprang the Vermandois of the line of Capet (q. v.), on whose extinction in the sixth generation Philippe II. annexed lands and title to the crown of France. Philippe III. bestowed V. on Charles, his younger son (1285), whose son ascended the throne of France as Philippe VI. (q. v.) in 1328, and was first of thirteen French kings of the House of V.—Jean II. (b. 1310; succeeded 1350; died in the Tower of London, 1364), Charles V. (q. v.), Charles VI. (q. v.), Charles VII. (q. v.), Louis XI. (q. v.), Charles VIII. (q. v.), Louis XII. (b. 1462; succeeded 1498; d. 1515), François I. (q. v.), Henri II. (q. v.), François II. (q. v.), Charles IX. (q. v.), and Henri III. (q. v.). By the death of the last without male issue in 1589 the succession passed to the House of Bourbon (q. v.), and V. from the time of Philippe d'Orleans, brother of Louis XIV., belonged as a duchy to the Orleans family. See FRANCE.

Valo'nia, the commercial name for the acorn-cups of a species of oak named *Quercus Ægilops*, a native of S. Europe, Asia Minor, and Syria. V. is largely used by tanners and dyers, and forms an article of considerable export from Asia Minor.

Valparai'so ('the vale of Paradise'), the chief seaport of Chili, is situated in a province of the same name, 90 miles W.N.W. of Santiago (q. v.), the capital, with which it is connected by railway. It is built at the base of steep, bare hills about 1600 feet high, and round the head of a bay which possesses good anchorage, but is exposed to northerly winds, and therefore unsafe in winter. The streets are narrow and often steep, but are well paved, and some of them are traversed by tramways. The houses are substantial, and often elegantly decorated. The public buildings include a number of important educational and charitable institutions, besides churches and theatres. The city has been greatly damaged by earthquakes on various occasions (notably in 1822, 1829, and 1851), as well as by a bombardment by a Spanish fleet on 31st March 1866. The climate is good, but dry, little rain falling except during the three winter months. The annual mean temperature is 58°. V. is the headquarters of the Pacific Steam Navigation Company, which was inaugurated in 1840, and in 1877 had a fleet of 58 vessels and a capital of £4,000,000. The total value of the import trade of V. in 1877 was $15,667,440, and of the exports $8,900,020. The chief items of the latter were copper and copper ore, gold, silver, cereals, wool, hides, and tallow. The pop. of the province (1877) was 180,324, and of the city (1875) 100,926, of whom 6738 were foreigners, chiefly English, Americans, and Germans.

Val'py, Richard, D.D., born in Jersey, 7th December 1754, from the college of Valognes (1764-69) in Normandy proceeded to Southampton Grammar School, and thence to Pembroke College, Oxford. Ordained in 1777, he held a living at Bury-St.-Edmunds, and from 1781 to 1830 was head-master of Reading Grammar School, which he raised to a state of high efficiency. He died at Kensington, 28th March 1836. His Greek and Latin Grammars enjoyed in their day a great reputation; and his brother Edward V. (1764-1832), head-master of Norwich School from 1810, was also well known by his *Elegantiæ Latinæ* (1803; 11th ed. 1836), an edition of the Greek Testament (3 vols. 1810), and other works.

Val'ue, in common language, means worth. But this worth may be of two kinds, V. in use and V. in exchange. Thus air has great V. in use, but in exchange it has none at all; whereas a bank-note has V. only in so far as it can be exchanged. In political economy it is only V. in exchange that we consider. Its discussion is one of the most important parts of that science. The main outlines of the theory of the subject may be thus stated: V. ultimately depends on mental appreciation, and that is determined by two elements, utility and difficulty of attainment. Utility alone does not make a thing valuable, neither does difficulty of attainment; V. depends on the existence of both. Accordingly, as these exist in a greater or less degree, we will procure a greater or less quantity of something else in exchange for the special article, and that is what we mean by V. It follows that V. is a relative term. It represents the relation of one thing to another. If A = B to-day and = 2B to-morrow, we say that the V. of A has risen, but we may also say the V. of B has fallen. Thus a general rise or fall of values is impossible. We may make this assertion of prices with perfect truth. The reason is that price is a particular case of V., but what do we mean when we say that there has been a rise in prices? Simply that the V. of money has fallen. It follows from this that there can be no invariable standard of V., although economists of such eminence as Adam Smith, J. B. Say, Ricardo, Malthus, Torrens, and James Mill, led away by false notions of the cause of V., have maintained that such a standard to be of any use at all must be invariable. It is quite true that the standard must not fluctuate rapidly, and this has been so generally though perhaps unconsciously recognised, that in all civilised countries the precious metals have been selected to fulfil this purpose. Three classes of articles possessing V. are recognised in political economy—(1) those which are strictly limited in quantity, as antique gems or pictures by a dead artist; (2) those of which the quantity can be increased, but only by the expenditure of a proportionally greater quantity of labour, as agricultural and mining produce from a limited area; (3) those whose quantity can be (practically) indefinitely increased without increase of cost of production. The V. of the first of these depends on the 'effectual' demand, meaning the mental appreciation of those able to pay a sufficient price for them; as is the demand so is the V. In the case of articles of the second class, the efficient demand also regulates the V., but not so exclusively, nor is the price forced up so rapidly by an increased demand or lessened supply. In no case can the price of these fall permanently below the cost of production, by which phrase we mean the ordinary remuneration to the capital and labour employed in their production. The V. of the third class of articles is in the long run determined by cost of production, though at any particular period and within a small limit by supply and demand. In a free country the competition of capital prevents any trade from reaping for a long period exceptional profits. Thus, if there be a great demand for guns, the price rises rapidly, but this attracts men of means into the trade, new manufactories are built, any required amount of guns are made, and as the supply becomes increased the price falls. Indeed it generally happens that in cases of this kind the thing is overdone and the market glutted. The V. of the article then falls for a considerable period. This is in brief the explanation of the ups and downs which we often observe in the history of some trades, such as the cotton, which are liable to violent fluctuations. It is to be carefully noted that the theory stated above is liable to many apparent exceptions. The actual exact price of an article is often dependent on the respective degrees of shrewdness that the buyer or seller may possess; what Adam Smith has termed the 'higgling of the market.' But the economic laws that regulate V. always act ultimately with powerful effect. As has been expressively said, they are like the force of the sun's attraction which determines the elliptical path of a planet's motion, which path is on the whole preserved, even though the real motion of a planet actually consists of endless deviations from it. See Bailey's able treatise on V. (Lond. 1825), as also the works of Ricardo, J. S. Mill, Fawcett, and De Quincey, for a full exposition of the subjects.

Vám'béry, Armin'ius or **Her'mann**, a distinguished traveller and orientalist, was born in 1832, of Jewish parentage, at Szerdahely, in Hungary, on an island of the Danube. Escaping from the tailor's bench to which his family would have condemned him, he succeeded amid much privation and hardship in laying the foundations of wide linguistic scholarship, first under the Piarists of St. Georgen near Pressburg, and afterwards at Vienna and Pesth. Expelled from Pesth by the Austrian authorities for his connection with the Revolution of 1848, the young teacher of languages removed to Constantinople (1854), and there maintaining himself as French tutor to Afif Bey and Rifaat Pasha, he made a thorough study of Arabic, Turkish, and Persian. In 1863, under the auspices of the Academy at Pesth, he successfully accomplished a most adventurous journey in Turkestan, passing in safety, under the disguise of a dervish and the pseudonym of Reshad Effendi, through the fanatical Mohammedan cities of Khiva, Bokhara, and Samarcand. He still holds the chair of oriental languages and literature in the University of Pesth, to which he was appointed in 1865; and he has become universally known not only as a master of Eastern lore, but as one of the keenest observers of Eastern politics. A strong believer in the regenerative power of Western civilisation, he is almost as strongly a partisan of English as opposed to Russian influence. Besides the narrative of his great journey, which appeared in German, English, and Hungarian in 1865, he has published *Deutsch-Türkisches Wörterbuch* (Constan. 1858), *Abuschka: A Dschagatai-Hungarian Dictionary* (Pesth, 1861), *Dschagataische Sprachstudien* (Leip. 1867), *Sketches in Central Asia* (Lond. 1867), *Wanderungen und Erlebnisse in Persien* (Leip. 1868), *Uigurische Sprachmonumente und das Kudalku-Bilik* (Leip. 1870), *Geschichte Bokhara's* (Stuttg. 1872; in English, *History of Bokhara*, Lond. 1873), *Central Asian and Anglo-Russian Frontier Question* (Lond. 1874), *Islam im 19 Jahrhundert* (Leip. 1875), *Sittenlehre aus dem Morgenland* (Berl. 1876), *Etymologisches Wörterbuch der Turkotatarischen Sprachen* (Leip. 1877). V. is a frequent contributor to periodical literature in England, Germany, and Hungary.

Vam'pire, the name applied to various species of *Cheiroptera* (q. v.) or Bats belonging to the family *Phyllostomidæ*. Although natives of S. America, they also occur in California and the southern parts of the United States. The nose and ears are provided with foliaceous or leaf-like appendages. The typical V. bat is the *Phyllostoma spectrum*, which attains an expanse of wing measuring 2½ feet. It has undoubtedly the habit of sucking the blood of quadrupeds. The genera *Desmodus* and *Diphylla* also include species of V. bats. In *Desmodus* the stomach has its anterior end dilated so as to form a great sac or bay, larger than the animal's body, and which lies folded on itself. The purpose of this sac is to receive the blood, which is thence slowly drawn into the intestine. The two upper incisors in these bats are sharp and pointed, and the four lower incisors are comb-like. The canines are large and sharp, and the molars (two above and three below in each side of each jaw) have sharp crowns.

Vam'pire (Russ. *vampir*, South-Russ. *upuir*, anc. *upir*, perhaps from a root *pi*, 'to drink,' with the prefix *u*, *av*, or *va*), the ghastly creation of a widespread superstition, rifest among Slavonic races—a demon, namely, that sucks the life-blood or devours the heart of its sleeping victim. Such demons are held in White Russia and the Ukraine to be dead wizards, were-wolves, heretics, and such-like outcasts; but by Bulgarian and Servian belief, any one, whatever his former life, may become a V., over whose corpse a cat or boy jumps, or a bird takes its flight. Earth rejects these monsters, who therefore know no decay; and on the discovery of a V.'s grave—effected in Servia by driving a coal-black colt through the churchyard, and marking the spot that he will not pass—the body, all fresh and ruddy, must be disinterred, thrust through with a white-thorn stake at a single blow, and burnt. The English custom of piercing suicides' bodies with a stake was a late survival of the same belief, which Tylor recognises in the Polynesian *tii* or departed spirits that steal from their graves to feast on a sleeper's heart and entrails, in the *hantu penyadin* of the Malayan Mintira, the dog-headed water-demon with alligator mouth which sucks men's great toes and thumbs so that they die, and in the Karens' *kephu* or wizard's stomach, which, under the form of a head and entrails, eats human souls. Tylor, ascribing the superstition to 'Animism,' considers vampires to be 'causes conceived in spiritual form to account for specific facts of wasting disease;' while Afanasief regards them as the thunder-god and spirits of the storm, who during winter sleep in their cloud-coffins a deathlike sleep, but with spring's return assume new life, 'and draw rain from the clouds, or, in mythical language, suck blood from sleepers.' See vol. ii. ch. 15 of Tylor's *Primitive Culture* (Lond. 1871), Ralston's *Songs of the Russian People* (2d ed. Lond. 1872), and his *Russian Folk Tales* (Lond. 1873).

Van, a fortified town of Armenia, Asiatic Turkey, about 145 miles S.E. of Erzerûm, on the S.E. shore of lake V. The town is neglected and in part ruinous. It is the seat of a governor, has a citadel and ruined fortifications, carries on cotton manufactures, and trades in fish, fruits, goatskins, and potash. Several cuneiform inscriptions have been found in the vicinity. Pop. 12,000-15,000 (chiefly Armenians). Lake V. has an area of 1424 sq. miles; it receives eight streams, but has no outlet. Its water is salt.

Vana'dium (V = 51·2), a rare metallic element occurring in nature as the vanadate of lead and the vanadate of copper. The metal, obtained by the ignition of the dichloride in hydrogen, is a greyish-white powder minutely crystalline. It burns vividly in oxygen, is insoluble in hydrochloric acid, dissolves slowly in hydrofluoric acid with evolution of hydrogen, and rapidly in nitric acid. It forms five oxides, of which the *dioxide* (V_2O_2) was regarded by Berzelius as the element itself. Indeed, many of the V. compounds may be looked upon as compounds of *vanadyl*, as this radical is called. The tetroxide (V_2O_4) or vanadious oxide is obtained in blue shining crystals by oxidation of the trioxide (V_2O_3) and dissolves in acids, forming bright-blue solutions of vanadious salts. It also acts upon the more basic metallic oxides forming *vanadites*, all of which, excepting those of the alkali metals, are insoluble in water. The pentoxide or vanadic oxide (V_2O_5) has a reddish-yellow colour, yields crystalline compounds (vanadic salts) when treated with the stronger acids, but acts more readily upon bases forming *vanadates*. Three chlorides are known, and four oxychlorides, or, as they may be called, vanadyl chlorides. Corresponding bromides have also been obtained, as also sulphides and nitrides.

Van'brugh, Sir John, an English dramatist and architect of the 17th c., son of Giles Fletcher of Chester, a Fleming by descent and a sugar-baker by trade, who married a daughter of Sir Dudley Carleton, and was considered by Thomas Fuller worthy to serve as patron to a portion of his *Pisgah Sight of Palestine*. Of V.'s early years nothing is known except by inference. He entered the army, and appears to have attained the rank of captain. In 1695, at John Evelyn's recommendation, he was appointed secretary to the commissioners for completing Greenwich Hospital. In 1697 his first play, *The Relapse*, was acted at Drury Lane; its brilliant success was at once brilliantly followed up by *The Provoked Wife* at Lincoln's Inn Theatre. His next effort, *Æsop*, was a failure with the crowd on account of its ostentation of moral instruction; but he somewhat regained his place by *The Pilgrims* in 1700. In 1702 he appeared in the new character of architect, and his designs for Castle Howard were so highly appreciated that his hands were soon full of similar commissions; and when the erection of Blenheim Palace was decreed by Parliament, he was entrusted with the preparation and execution of the plans. While engaged on Blenheim he built a theatre in the Haymarket, and brought out his dramatic masterpiece, *The Confederacy* (1705). In 1703 the Earl of Carlisle, for whom Howard House was designed, had procured V. the post of Clarencieux King-at-Arms, and as such he conveyed the insignia of the Garter to the King of Hanover in 1706. In 1714 he was appointed Comptroller of the Royal Works, and in 1716 surveyor of the works at Greenwich Hospital. He died March 26, 1726, leaving unfinished the play of *The Provoked Husband*. As a dramatist, V. displays the same kind of vivacious wit and undisguised indecency which characterised the other dramatists of the day; but he has a naturalness and fluency peculiar to himself. Collective editions of his plays were published in 1730, 1735, 1759, and 1776, and in 1840 Leigh Hunt associated them in one volume with those of Wycherley, Congreve, and Farquhar. See Leigh Hunt's *Biograph. and Crit. Notice*; several valuable letters of V. published by Hepworth Dixon in *Athenæum*, January 19, 1861; and *Notes and Queries* (2d Series. vols. iii., iv., xi.).

Vancou'ver's Island, included in the Dominion of Canada as part of the province of British Columbia, lies off the Pacific coast in lat. 48° 20'-50° 55' N., and long. 123° 10'-128° 20' W. On the one side it is washed by the Pacific, while the Strait of Georgia and Puget Sound separate it from the mainland, and communicate with the ocean in the N. by Queen Charlotte's Sound, and in the S. by the Strait of San Juan de Fuca. V. I. is 300 miles long by 70 broad, and has an area of 18,750 sq. miles. The shores, especially in the W., are marked by beetling cliffs and picturesque fiords (called canals), while the interior is traversed by a mountain-ridge, which attains its greatest height of 7211 feet in Victoria Peak, of 6300 in Crown Mountain, and of 5900 in Mount Arrowsmith. The surface is in great part a waste of rocks, but here and there, especially in the S.E., there are large tracts of undulating, thickly-wooded land, alternating with grassy glades. The streams, none of which are navigable, descend in flood during winter. The climate closely resembles that of Scotland, except that it is more rainy. Only one-fifth of the surface is cultivated, but there is an abundant yield of wheat, oats, barley, root-crops, and apples. The arable soil, which is of the most productive character, is well adapted for all ordinary crops, except Indian-corn. V. I. is rich in minerals, containing valuble deposits of gold, copper, iron, silver, lead, and other ores, and of coal of Tertiary origin, part of which is anthracite of good quality. The forests are infested by the puma, bear, wolf, &c., and game is abundant, comprising two kinds of deer, wild-fowl, grouse, and snipe. The fisheries of salmon, sturgeon, cod, herring, haddock, halibut, whiting, &c., are very productive, and supply most of the towns along the American coast. The timber trade is only inferior in importance to the fisheries, and the woods exported include cedar of seven feet diameter, and white fir or Douglas pine, highly valued for making spars. There is some shipbuilding. The chief town is Victoria, which had a pop. in 1871 of 4540, and is the capital of Columbia. The census of 1871 gave no returns for the island apart from the province, but the predominating inhabitants are Indians, who number 18,000. They are mostly tribes belonging to the confederation of the Nootkas (q. v.), and have among them several missions maintained by the Roman Catholics. V. I. constitutes a Roman diocese, and contains three convents, one seminary (St. Louis College), and three academies. The Anglican churches are under the Bishop of Columbia. The island, originally called Nootka, was discovered by Juan Perez and Martinez in 1774, and partly explored by Quadra (1775) and Cook (1778), but first circumnavigated by Captain George Vancouver in 1792. After the American boundary dispute it was secured to Britain by the Oregon Treaty of 1846. It was leased to the Hudson Bay Company 1846-49, was constituted a distinct British colony in 1863, and finally united to Columbia in 1865. The projected Dominion-Pacific Railway is to be carried from the mainland to the island by means of a mighty viaduct over Seymour's Narrows.

Van'da, a genus of *Orchidaceæ* remarkable for the large size and great beauty of the flowers. There are about 20 species, all epiphytal and all natives of tropical Asia. *V. Batemanni, cærulea, gigantia, Lowii, suavis,* and *tricolor,* are among the most conspicuous orchids grown in European hot-houses.

Van'dals, a Teutonic people, originally inhabiting the lands between the Warthe and the Baltic, described as occupying the Riesengebirge at the time of the Marcomannic War (166-180 A.D.), and in the reign of Probus (276-282) dwelling to the N. of the Lower Danube, beside the Goths and Gepidæ, where they suffered much at the hands of the Goths till 334, when Constantine the Great assigned them settlements in Pannonia. About the beginning of the 5th c. they turned to the W., and in 406, along with the Suevi and Alani, under the leader Godegisel, entered Gaul, where they waged destructive war, till Godegisel fell in battle with the Franks. His son Gunderic then led the V. into Spain (409), where they were pressed by the West Goths to the central and S. parts, called after them *Vandalitia* (Andalusia). Hence their king Genseric or Geiseric led them over to Africa (429), where they conquered Carthage (439), and established an empire including the N. coast of Africa as far as Cyrenaica. The V. now took to piracy on the Mediterranean. In 455 Genseric disembarked at Ostia. Maximus being slain in a seditious tumult, Rome fell an easy prey to the V., who pillaged it fourteen days, and carried off by sea a rich booty. The queen, Eudoxia, two princesses, besides thousands of noble captives, were among the spoils. The unsparing destruction of the richest art-treasures of the capital by these irreverent barbarians has made *Vandalism* the common name for all such outrage. On the accession of Odoacer, King of the Heruli, to the kingdom of Italy (476), the V. obtained for their services Sardinia, Corsica, the Baleares, the Pityusæ, and the S. of Sicily. The death of Genseric in 477 marks the beginning of the decline of the Vandal power, which was hastened by the persecutions they as Arians carried on against the Orthodox Catholics. Genseric's successors were Hunneric (477-484), Gundamund (484-496), Thrasimund (496-523), and Hilderic (523-530). Gelimer having conspired against Hilderic his cousin, and seized the crown (530), Justinian sent an army to Africa under Belisarius, who landed at Caput Vedæ in 533, and defeated Gelimer near Carthage, which thereafter surrendered. Gelimer collected another army, but was decisively defeated by Belisarius in 534. After gracing the triumph of his conqueror he received an honourable exile in Galatia. What were left of the V. enlisted into the imperial army or disappeared among the races of Africa. See Papencordt, *Geschichte der Vandalischen Herrschaft in Afrika* (Berl. 1837).

Van'derbilt, Corne'lius, born of humble Dutch parentage at Staten Island, New York, 27th May 1794, after a meagre education turned waterman at an early age, and from his seventeenth year ran a ferry-boat of his own between New York and Staten Island. Thus and as schooner-master he had acquired $9000 by 1817, when, entering the service of Thomas Gibbons, he became captain of a New York-New Brunswick steamer, and an hotel-keeper at the latter place. In 1829 he started steamboats of his own upon the Hudson, in 1851 opened the Nicaraguan steam-line to California, and in 1855, having visited Europe two years before, established the Havre-New York service. His gift to Government of a splendid steamer (1862) earned him the thanks of Congress, and subsequently engaging in railroad enterprise, he became the president of four railway companies. One of the wealthiest of the Union's citizens, he presented $1,000,000 to the Central (now Vanderbilt) University of the Methodist Episcopal Church, which, founded at Nashville, Tennessee, in 1872, and opened in 1875, possesses the four departments of theology, law, medicine, and philosophy, and has 26 instructors and over 300 students. V. died at New York, 4th January 1877, leaving a son, William Henry W., who, born in New Brunswick, 8th May 1821, was elected vice-president of the Hudson River Railway Company in 1873.

Van'dervelde, Willem, a Dutch marine artist, son of Esaias V. (1587-1654), was born at Leyden (1610) and brought up to a seafaring life, but became an effective designer of shipping. He is said to have made drawings from actual observation of the battle between the Duke of York and Opdam and the memorable three days' engagement between Monk and Ruyter. Crossing to England in 1675, he was engaged as painter of sea-fights to Charles II. and James II. successively, with an annual pension of £100. He died in London, 1693. With absolutely no pretension to colour, his drawings are delicately finished, and have some value as historical illustrations. He is called 'the Elder,' to distinguish him from his son, **Willem V.,** commonly known as 'the Younger,' who was born at Amsterdam in 1633, and who surpassed his father as a painter of marine effects. Like 'the Elder,' he was a faithful art-chronicler of naval events, and by order of the Duke of York attended in a small vessel the engagement of Solebay, and from drawings made on the spot painted a large picture of the review of the English and French fleets by Charles II. at the Nore. He died at Greenwich, 6th April 1707. The best works of V. are in the Bridgewater Gallery. Ruskin says that instead of the tremulous, turbulent ocean of nature, the Vanderveldes painted waves 'that curl up like shavings,' with foam 'set astride' upon them 'like a peruke.'—**Adrian V.,** brother of the preceding, born near Rotterdam, 1659, was a remarkable painter of animals and landscapes, and also acquired a high reputation as an engraver. He died at Amsterdam, January 21, 1672.

Van Dyck. See DYCK.

Vane, Sir Henry, one of the most prominent figures in the history of the Civil War and the Commonwealth, was born in

the year 1612. He was the eldest son of Sir Henry V. (1589-1654), afterwards Baron V., of Raby Castle, who filled several high offices of state under James I. and Charles I., but fell into disgrace through the enmity of Strafford, and afterwards lived in retirement, taking no active part in the war. V. himself, after a thorough education at Westminster and Magdalen College, Oxford, where already his heterodox views began to make themselves apparent, went abroad and remained for some time in France and at Geneva, where he contracted views strongly opposed to the Anglican form of church government and the monarchical form of temporal power. Returning to England, he found that his opinions exposed him to much ill-will and unpleasantness at the hands of his father as well as from strangers, and he consequently determined to emigrate to America. He landed in New England in 1635, and his ability and strength of character were already so marked that he was almost at once elected Governor of Massachusetts. He seems, however, to have been yet more independent and republican than the independent and democratic colonists, for he held office little more than a year, and returned to England in 1636. He now married, and was partly, at least, reconciled to his father, who procured for him the office of Treasurer of the Navy in conjunction with Sir William Russell. In 1640 he was knighted and sat for the borough of Hull in the Parliament of that year, as well as in the Long Parliament which assembled in November. He was now sole Treasurer of the Navy, and the fees of his office amounted, it is said, to nearly £30,000 a year, all of which he resigned to Parliament, stipulating only that £2000 a year should be continued to his deputy. In Parliament he was one of the most vigorous opponents of Laud and Strafford, especially of the latter, against whom he was embittered by family hatred as well as political resentment. He was one of the commissioners sent to Scotland in 1648, and became a member of the Council of State in the following year, rising to the office of president in 1652. He was in no way directly concerned in the execution of Charles I., though his moderation in this respect stood him in little stead afterwards. His Republicanism was far too sincere and thoroughgoing to permit of his acting in concert with Cromwell. When the Protector forcibly dissolved the Long Parliament in 1653 he openly attacked V. as 'a juggling fellow,' and the latter became a consistent opponent of his usurpations. A pamphlet called *A Healing Question Propounded and Resolved*, which he published in 1656, led to his imprisonment for some time in Carisbrook Castle, which did not, however, deter him from continuing resolutely to oppose the government both of Cromwell and of his son Richard. On the latter's abdication V. was again for a short time in the ascendant, and became a member of the Committee of Public Safety and of the Council of State, of which he was ultimately president. But as Parliament began to tend more and more towards monarchism his star waned, until at length he was ordered to repair to his estate of Raby Castle and remain there during the pleasure of the Government. The Restoration found him still in this retirement, and, trusting to the general amnesty declared for all who had not been actively concerned in the execution of Charles I., he did not attempt to escape. A special exception, however, was made in his case, he was seized (February 1660), imprisoned in the Tower, and afterwards moved from prison to prison, being one time taken as far as the Scilly Isles. At the commencement of his imprisonment Parliament had petitioned that whatever punishment might be awarded him his life should be spared, and the king had to all appearance acceded to the petition. Nevertheless, a rising of the Fifth Monarchy party with which he had been connected (January 1661) led to increased rigour against him, and he was ultimately brought to trial. He defended himself boldly and ably, but was sentenced to be hung, drawn, and quartered at Tyburn, which sentence was afterwards altered by a special act of grace, and he was beheaded on Tower Hill on the 14th of July 1662. He published several works on politico-religious subjects full of the obscure mysticism which characterised his views on religion. He had actually a sect of disciples called by Burnet *Seekers*, and by Baxter *Vanists*. See *The Life and Death of Sir Henry Vane, Knight* (Lond. 1662).

Vanill'a, a small genus of *Orchidaceæ*, natives of tropical America and Asia, and distinguished from most other orchids by their climbing habit. The twining, four-angled, somewhat succulent stem ascends trees to a height of from 20 to 30 feet, producing oblong fleshy leaves and throwing out roots at the nodes. The flowers are dull-coloured. V. is unique among *Orchidaceæ* in furnishing an article of commerce, the 'V. pods' used by perfumers, chocolate-makers, and confectioners being the fruit of *V. planifolia*, a native of Central America. The seed-vessel is cylindrical, with a diameter of about a third of an inch and a length of 8 inches. It is gathered before the seed is ripe, is dried in the sun, steeped in an oil, and made up into small bundles for export. V. has a strong peculiar agreeable odour and a sweetish aromatic taste. It acts as a gentle stimulant, and promotes digestion; in large doses it is considered to be a powerful aphrodisiac. It has been used medicinally in hysteria. The odorous principle, *vanillin*, can be made artificially, being the methylic aldehyde of pyrocatechuic acid, and is manufactured from the sap of *Coniferæ* as an article of trade. The plant is cultivated in the West India Islands, Ceylon, and Mauritius, but that from Mexico is most esteemed. Other species of the genus, as *V. Guianensis*, produce an inferior commercial V.

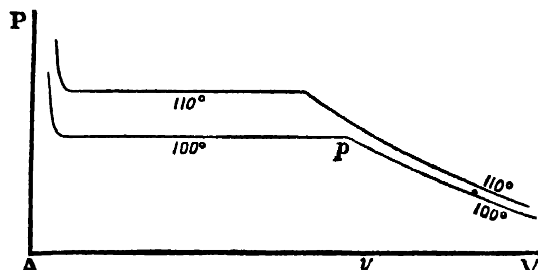
Vani'ni, Lucil'io (or, as stands on his title-pages, **Julius Cæsar**), owes his celebrity for the most part to his martyrdom in the cause of free thought. Born at Taurisano, near Otranto, in 1584, he studied at Rome, Naples, and Padua, and having joined the order of the Carmelites, wandered through Switzerland, Germany, the Netherlands, and France, preaching, teaching, debating, and attracting attention by his vivacious ability. From the threats of the Inquisition he fled to England; but, though he was admitted a member of the English Church by Abbot, Archbishop of Canterbury, his conduct was too independent for a proselyte, and for no other reason he was actually imprisoned in the Tower. On his release he went to France, where he published the two works by which he is still known—*Amphitheatrum Æternæ Providentiæ Divino-Magicum, Christiano-Physicum, Astrologico-Catholicum adversus veteres Philosophos, Atheos, Epicureos, &c.* (Lyon 1615), and *De Admirandis Naturæ Reginæ Deæque Mortalium Arcanis* (Par. 1616). His defence of Christian doctrine was supposed to be a mere pretext for the presentation of the counter arguments, and on the strength of some dubious passages he was accused of heresy, and in due course sentenced as an atheist to have his body burned and his ashes scattered to the four winds. His execution followed on February 19, 1619, and his memory has been blackened by the representatives of his clerical foes. In philosophy V. was an ardent follower of Averroes. See Schramm, *De Vita et Scriptis Famosi Athei J. C. Vanini* (Kustrin 1709); Arpe, *Apologia pro J. C. Vanini* (Rott. professedly Cosmopolis, 1712); Fuhrmann, *Leben und Schicksale des L. V.* (Leip. 1800); R. Palumbo, *Giulio Cesare Vanini e i suoi Tempi* (Naples 1878); and *General Sketch of the History of Pantheism* (Lond. 1879, vol. i.).

Vanloo', Jean Baptiste, a French painter, was born of a Flemish family at Aix, in Provence, 14th January 1684. His grandfather, Jakob (1614-70), was one of the best of Flemish colourists, and his father, Louis (1640-1712), gained the first prize of the Paris Academy. Entering the service of the King of Sardinia, V. subsequently studied at Rome, and at Paris was made a member of the Academy in 1731, and a Professor of Painting in 1735. He lost considerably in the Mississippi Scheme, and crossed in 1738 to London, where he became the fashionable portrait-painter of the time. He died at Aix, 19th December 1745. Besides excellent portraits, he painted many feebly ambitious, historical, and mythological subjects.—**Carle André V.**, brother of the preceding, born at Nice, 15th February 1709, was for some time a decorative painter in Paris, but took to portrait-painting. After visiting Rome, and executing a series of works for the King of Sardinia illustrative of Tasso's *Gerusalemme*, he settled in Paris in 1734, received the order of St. Michael in 1751, and was appointed chief painter to Louis XV. in 1762. He died at Paris, 15th July 1765. His works, which comprise decorations, portraits, mythologies, and religious subjects, are lacking in expression and genuine dignity, but are among the finest productions of French art under Louis XV. See Dandré-Bardon, *Vie de Carle V.* (Par. 1765); and A. Housaye, *Les V.* (*Revue des Deux Mondes*, August 1, 1843).

Vannes, the capital of the department of Morbihan, France, on the Marle, 32 miles S.W. of Rennes by rail. It consists of an upper and a lower town—the former, mostly new, slopes up a high hill, the latter consists largely of old wooden buildings forming crooked streets in the valley below. None of the

ancient buildings are of much interest. The cathedral of St. Pierre, burnt by the Normans, but rebuilt in the 13th and 14th centuries, and the Chateau de l'Hermine, a ruined tower in the centre of the town, are the chief. Several convents have been transformed into the government buildings. Among the public buildings are the bishop's palace, barracks, three hospitals, &c. There are manufactures of ironmongery, lace, calico, and other textile fabrics, paper, beer, and salt; also shipbuilding and fisheries. The trade consists in corn, sardines, hemp, butter, honey, wine, salt, wax, cider, and iron goods. There is a small harbour and canal leading to Morbihan bay. Pop. (1876) 15,716. V. was the ancient *Dariorigum Venetorum*. It was taken by Pippin the Frank in 753, and by the English in 1342.

Van Ren'sselaer, Henry Kilian, an American patriot of Dutch descent, was born at Albany, U.S., in 1744, commanded a regiment in the War of Independence, distinguished himself on several occasions, and in October 1777 aided in the actions which led to the surrender of Burgoyne. After the peace a famous mutiny broke out among his troops. He died at Greenbush, New York, 9th September 1816.—**Solomon V. R.**, son of the preceding, was born 9th August 1774, had a distinguished military career, shared in the brilliant attack on Queenstown Heights, 13th October 1812, and died at Albany, 23d April 1852.—**Stephen V. R.**, 'the patroon,' was born at New York, 1st November 1764, graduated at Harvard 1782, was member of State-senate 1790–95, Lieutenant-Governor 1789–1801, and from 1810 a leading Commissioner for the Erie Canal Scheme. In 1812, as a colonel of militia, he led the attack on Queenstown. In 1819 he was made Regent of New York University, and subsequently instituted the geological survey of New York, and founded the Troy scientific school. In 1824 he published the *Geological and Agricultural Survey of the District adjoining the Erie Canal.* He died at Albany, 26th January 1830.



Vanucci. See PERUGINO.

Van Veen or **Ve'nius, Otho**, a Dutch painter, born at Leyden about 1556, studied under Zucchero at Rome, and was the first who explained the principles of chiaroscuro to Flemish artists. He was invited by the Emperor Ferdinand II. to settle in Vienna, but returned to Holland and served the celebrated Alexander Farnese, then Governor of the Spanish Netherlands. On the death of his patron he opened an academy at Antwerp, where Rubens was among his pupils. He was appointed Master of the Mint at Brussels, and subsequently declined the invitation of Louis XIII. to visit Paris. He died at Brussels in 1634. V. was an able painter of allegories and religious groups, but is chiefly remembered as 'the master of Rubens' (*Reynolds*).

Vap'ereau, Louis Gustave, a French littérateur and editor, born at Orléans, April 4, 1819, won (1838) the prize for philosophy in a competition between all the colleges of France, became private secretary (1842) to Victor Cousin, whom he assisted in his *Pensées de Pascal*, and after spending some years as a professor in a college at Tours returned to Paris, where he passed *avocat* (1854), but devoted himself to literature. His best-known work is the *Dictionnaire des Contemporaines* (1st ed. 1858; new ed. 1870), which is equally admirable for the fulness of its knowledge and the felicity of its criticism. Since 1859 V. has issued yearly *L'Année Littéraire et Dramatique*, an annual review of the chief products of the national literature. Another important work of V.'s is his *Dictionnaire Universel des Littératures* (Par. 1876).

Va'pour is generally understood to mean the gaseous form which a solid or liquid substance assumes when heated. It is therefore essentially a gas; and now that all known gases have been liquefied, there is no physical difference between an ordinary gas such as oxygen and a V. such as steam. By Rankine, however, the term is used in a restricted sense; and in this connection we propose to consider it now, referring to GASES for the general laws which more or less approximately hold for all bodies in the gaseous condition. The effect of heat upon a liquid is fourfold. It may warm the liquid, *i.e.*, raise its temperature; it may alter its volume; it may alter its physical state as a liquid, *i.e.*, make it more or less mobile; and it may convert it into V. This last phenomenon, *evaporation*, takes place with most liquids, and even with many solids, at ordinary temperatures, as is evidenced by the gradual decrease in quantity of water exposed to the open air, or by the smell which many substances possess. If a liquid partially fills a vessel from which air has been exhausted, it is found that the vessel becomes filled with vapour, the density of which depends only upon the temperature. If the remainder of the vessel contains any quantity of air or other gas not capable of chemically acting upon the liquid, exactly the same quantity of V. will be formed, only the time taken by the V. in attaining its maximum density will be greater. These laws of evaporation were discovered by Dalton, and show that for every V. in contact with its liquid or solid there is a maximum density which the V. has at that temperature. Hence, for each temperature there is also a maximum pressure which the V. can exert, since in all substances the density, pressure, and temperature are so connected that given any two the third is also determined. A V. at its maximum density and pressure corresponding to its temperature is called *saturated* V.; and in this sense only does Rankine employ the word V.

Consider now a cylindrical vessel with a tightly-fitting movable piston, and filled with steam at 100° C. Also let the volume of the steam be such that its density is considerably below the maximum density of saturation corresponding to that temperature. If, in these circumstances, the piston is pushed in, the volume is diminished and the density and pressure proportionately increased. Throughout the operation we shall suppose the temperature to remain constant, so that, since steam behaves nearly the same as an ordinary gas provided it is not near its saturation point, the product pv (pressure × volume) is approximately constant. Hence, if we measure lengths representing volumes along the horizontal axis AV, and corresponding co-ordinates in the direction of AP drawn vertically, we shall be led to the

construction of a curve or *isothermal line*, expressing the relation between pressure and volume. This curve is approximately an hyperbola until the volume of the steam is so diminished that the pressure approaches the maximum point of saturation—until, in other words, the steam becomes V. in the restricted sense explained above. Let AV represent the volume, the corresponding pressure for which (vp in the diagram) is this maximum pressure of saturation; then any subsequent diminution of volume is accompanied by the condensation of the saturated steam as water at 100° C., and *there is no increase of pressure* as long as there is steam to condense. The isothermal line expressing the relation between pressure and volume will therefore be a straight line parallel to AV the line of volumes. When at length the steam is wholly condensed as water, any further diminution of volume is attended with a very great increase of pressure, so that the isotherm is then continued abruptly up towards P, as represented roughly in the diagram. If the same series of experiments be made when the substance is kept at a temperature of 110° C., the same peculiarities present themselves, except that the pressure of saturation is greater and the corresponding volume less than in the former case. The isotherm of 110° may be represented by a similar but higher curve, in which the break indicating the point of saturation takes place at a smaller volume but greater pressure. In this way a number of isotherms may be drawn; and it is found the higher the temperature the smaller becomes the straight portion of the line. Hence it is conceivable that for a certain high temperature this straight portion will disappear and the isotherm will become a continuously curved line. This *critical temperature*, as it is called by Andrews, has not been experimentally obtained for water, but it has been very thoroughly investigated by this distinguished physicist for carbonic acid. As early as 1822, Cagniard de la Tour observed that when liquids were strongly heated

in glass tubes of a capacity not much greater than the volume of the liquid, there was a certain temperature for which the substance hitherto partly gaseous and partly liquid suddenly assumed a uniform appearance. He concluded therefore that at this temperature the whole became gaseous, though the volume was very little greater than the original volume of the liquid. The true explanation was given by Andrews, who showed that the properties of the liquid and gas approach similarity as the temperature is raised, and that above a certain temperature they were not distinguishable. This result fully accords with Faraday's statement, that above a certain temperature peculiar to each gas no amount of pressure will produce the phenomenon we call condensation. By a series of elaborate experiments upon carbonic acid Andrews showed that the isotherm for 48·1° C. was a perfectly continuous curve, while that for 20·5° C. presented the broken characteristics we have described as belonging to the steam isotherm for 100° C. The isotherm for 31·1° C. just escapes having this characteristic, and therefore lies just above the critical temperature. We thus see that the properties of a gas may imperceptibly pass into those of a liquid without any break of continuity, so that the gaseous and liquid states are only widely-separated forms of the same condition of matter. The critical temperatures of most liquids are very high, so that their determination is difficult and dangerous, while the critical temperatures of the so-called permanent gases are very low, and have only lately been reached experimentally. For a fuller discussion of these curious relations between liquids and their vapours, see Clerk Maxwell's *Theory of Heat*.

Var, a department in the extreme S.E. of France, named from the river V. Area 2349 sq. miles; pop. (1876) 295,763. In the N. and N.E. it is mountainous. The chief rivers are the Gassau, Argens, and Loup. The soil is for the most part extremely fertile, though about 620,000 acres are still forest. The olive and the vine are its chief products, but the silkworm is also largely bred, and tobacco, oranges, wheat, and potatoes form important items in its returns. In 1876, 73,766,000 gallons of wine of all sorts were produced, 433 tons of silk cocoons, 242,000 qrs. of wheat, 2,640,000 bushels of potatoes, and 61,600,000 lbs. of olive oil; while in 1875 the coal production amounted to 83,500 metrical quintals. The capital is Draguignan (q. v.); other towns are Toulon (q. v.), Brignoles (q. v.), and Frejus (q. v.).

Varan'gians (Old Norse *Væringjar*, from *vár*, 'oath,' Gr. *barangoi*), a body-guard of Northmen first employed by the Greek emperors at Constantinople about the beginning of the 10th c., and who for centuries upheld the Byzantine throne. They were bound by an oath to the emperor, and subject to a strict military code. They were stationed at Kibotus near Hellenopolis on the Hellespont, where they were afterwards reinforced by the Ingloi, refugees who had fled from England before its Norman conquerors. At the death of the emperor they had the privilege of carrying off what they would from the imperial treasury. Traces of these V. or 'Warings' are seen in the Norwegian *Varenge-fjord*, *Wieringergaard* on the Dutch coast, *Varengeville* in Normandy, and the names of many places in England. See NORTHMEN, and the works there mentioned.

Vara'nus, an important genus of *Lacertilia* or lizards, including the 'Monitors,' so named from the belief that they warned persons of the approach of crocodiles by a peculiar hissing noise. The family *Varanidæ* are represented by some of the largest members of the lizard group. They are found in Asia, Africa, and Australia. The *V. Niloticus* of Egypt attains a length of from 4 to 6 feet, and the *Hydrosaurus sulcator* of the East Indian Archipelago occasionally 8 feet. The head and belly are covered with small scales, and the tongue is protrusible and fleshy. The teeth are lodged in a common groove, and there are no palatal teeth. The tail is compressed in the water-living species, and has a double row of carinated scales.

Varaz'ze, or **Voragine** (Lat. *Vicus Virginis*), a small town of N. Italy, province of Genoa, on the gulf of Genoa, 20½ miles distant by rail from the city of Genoa, has obtained of late some note as a shipbuilding place, mostly for the Genoese merchant service. Portions of the old fortifications are still standing, and in the Church of S. Ambrosio of the 12th c. there are some fine marbles and pictures. Besides the shipbuilding yards, in which 17 vessels were built in 1874, the town contains paper-mills and one or two cotton factories. Anchors, nails, cordage, and paper are manufactured. Pop. (1874) 9179.

Vare'se, a town of N. Italy, on a lake of the same name, 37½ miles N.N.W. of Milan by rail. The church of San Vittore (1567), with a tower 246 feet high, contains some good pictures, and several of the private villas, belonging for the most part to Milanese families, are extremely handsome. The sanctuary of Madonna del Monte, 8¼ miles N.W., commands a magnificent view. Silk and paper are the chief manufactures, but there are also large establishments for the making of furniture and smaller ware. Pop., with suburbs (1874), 12,605.

Varia'tion, in music, the rendering of the principal air or theme of a composition in a different manner, by changes in time, rhythm, or key, and harmonic and contrapuntal embellishments. It forms a useful exercise for the student, and has been a favourite subject even among the greatest masters, such as Mozart and Beethoven, giving great opportunity for ingenious and imaginative treatment.

Varia'tion of the Com'pass. See TERRESTRIAL MAGNETISM.

Varia'tions, Cal'culus of, an important branch of the differential calculus, was first systemically developed by Lagrange in 1760. Previous to this, the two Bernoullis had successfully attacked several problems which require the peculiar methods of the C. of V. for their solution. The first problem proposed by John Bernoulli was to find the *brachistochrone*, or the curve of quickest descent from one point to another under the action of gravity. The problem is one of maxima and minima, but its peculiarity as distinguished from problems solvable by the ordinary method of the differential calculus is, that not only must account be taken of variation of position *along* any one possible path, but also of variation of position in passing from one path to a contiguous one. There are thus two distinct kinds of differentiations to be treated, and the latter is distinguished as variation, and the symbol used δ, to avoid confusion with the d of the ordinary differential calculus. To find the curve which with given perimeter encloses the greatest area is a problem of the same nature as the brachistochrone problem, and was solved by the Bernoullis. Euler added much to our knowledge of the methods, which are now very much as Lagrange left them. Though its development is thus mainly due to the Continental mathematicians of last century, it must be noted that the first who solved a *variation* problem was Newton, who, in the scholium to the 34th proposition of the second book of the *Principia*, gives, without in any way indicating how he obtained the result, the construction for finding the form of the solid of least resistance moving in a resisting medium. See Jellet's *C. of V.* (1850); Strauch's *Theorie und Anwendung des Sogenannten Variationskalculs* (1850); Airy's small treatise, and Todhunter's *History of the C. of V.* (1860).

Varicell'a (Lat. 'a little pimple') is a disease popularly known as Chicken-pox (q. v.).

Var'icocele, or **Cir'cocele**, is a term used in surgery to denote a varicose condition of the pampiniform plexus of veins which returns the blood from the testicle into the spermatic vein. V., in its minor degrees, is a very common affection, and, in most cases, neither operative nor palliative treatments are necessary. When the V. is large, nothing is required but a bag-truss. If the enlarged veins should inflame, rest in the recumbent position, with the testicles raised by a small pillow, fomentations and leeches are indicated. In very severe cases operative interference has been found necessary, the operation being the same as for varicose veins of the leg.

Var'icose Veins, or **Va'rix**, is a very common affection as seen in the veins of the lower limb. It sometimes affects the veins of the spermatic cord, constituting the disease called Varicocele (q. v.); and the hæmorrhoidal veins, giving rise to Hæmorrhoids or Piles (q. v.). When any large trunk-vein is obliterated, the collateral circulation is frequently carried on by the subcutaneous veins, which consequently become dilated, tortuous, and varicose. V. V. in the lower extremities may be caused by

too great or too continuous a strain on the veins, or by any obstruction to the return of blood from them, the special causes being long-continued standing, especially in a heated atmosphere, too firmly applied garters, ill-fitting trusses, abdominal tumours, the gravid uterus, and relaxation of the tissues which should support the veins. The first stage of the disease is dilatation, which if long continued may become permanent. In consequence of the dilatation the valves become inadequate to close the vessel, and the pressure is transmitted to a lower part of the trunk, which becomes similarly affected. A considerable tract of the vein becomes tortuous and enlarged, constituting the condition called V. V. In the second stage of the disease the coats of the veins which are probably thinned by long-continued dilatations may give way altogether, and the skin over them being absorbed by the pressure may also give way, hæmorrhage being the result. In some cases, however, thickening of the veins is the result. The retardation to the return of the blood may cause, in addition to dilatation, congestion, exudation of serum, low inflammation, and ulceration, giving rise to varicose ulcers. The superficial veins are chiefly affected, but the deep veins may suffer similarly; indeed, Giacomini, a recent writer, asserts that varicosity of the superficial veins is always secondary to a varicose state of those deeper veins (inter- and intra-muscular) which establish a communication between the trunk veins accompanying the arteries and the subcutaneous vessels—the radicles of the saphenous. The *treatment* of V. V. may be palliative or radical. In the early stage complete recovery may ensue by removing the exciting cause, unloading the veins by rest in the raised posture, and by improving the tone of the tissues. The patient should remain in bed for a considerable time, and the affected limb should be elevated above the level of the body. If subacute inflammation is present, hot emollient fomentations should be applied; but if there is only œdema, a soft firm bandage should be applied. This mode of treatment, conjoined with the improvement of the general health, will at least relieve the more urgent symptoms, and may, if persevered in for a sufficient length of time, say a month, result in a radical cure. As there is always a tendency to a relapse, the patient should afterwards wear a well-fitting elastic stocking or a bandage, more particularly during any strong exercise. The indiarubber bandage, carefully applied, will be found to answer the purpose well, even in cases of long standing, when the veins have become much thickened.

The following is the mode of operation for the radical cure of V. V. introduced at St. George's Hospital by Mr. H. Lee. Two pins are to be passed under the vein at a distance of about an inch from each other. Compression is then made by twisting a figure-of-8 ligature round the pins or by a piece of indiarubber, through which the pin is thrust before it is introduced, and which is then drawn over its points. Then a thin knife is passed under the vein, and the latter completely divided without cutting the skin. Two or three circular pieces of plaister encircling the whole leg are then firmly applied over the puncture and the divided ends of the vein; and the patient is kept in bed, with the limb raised, for a week or ten days. The pins are removed one at a time within from two to five days. The plaister need not be removed unless suppuration is found to be going on. When the parts have healed, an elastic stocking should be worn.

Vari'ety (1) in *Natural History*. When a *species* of animals *varies*, and produces individuals which differ in certain points, such as size, colour, &c., from the specific type, these aberrant individuals constitute *varieties* of the species. Thus a white or albino elephant is a 'V.' of the ordinary Indian species. The causes of *variation* in animals and plants are obscure—change of food or climate being obvious external causes, while many undetermined and internal causes of variation also exist. It may be noted that variation is the literal keynote of Darwinism and other theories of organic evolution. (2) In *Botany*. When a large number of the individuals of a *species* differ from the others in any striking particular they constitute a V. If the V. generally comes true from seed, it is often called a *race*. A V. can only be propagated with certainty by grafts, cuttings, bulbs, tubers, &c. A race may with care be propagated by seed. A real species will always come true from seed.

Vari'nas, or **Bari'nas**, capital of the province of Zamora, or V., Venezuela, on the San Domingo, 290 miles S.W. of Caracas. It was formerly a considerable town, and manufactured great quantities of the V. tobacco. This industry was greatly interfered with during the civil war, and V. now exports chiefly coffee, cocoa, and cattle. Pop. (1873) 3950.

Var'na, the chief Black Sea harbour of the principality of Bulgaria, situated on a crescent-shaped bay, at the mouth of the Paravadi, to the S. of Cape Kaliakra, and 170 miles N.N.W. of Constantinople, with which it has communication by regular steam lines. It is the terminus of the railway from Rustchuk, constructed in 1866, and is girt by a high wall and a deep ditch, while strong batteries command both town and harbour. The seat of a Greek metropolitan and the residence of several foreign consuls, V. has, besides a citadel, several mosques, large storehouses, a lazaretta, &c. The harbour is exposed to S.E. winds: on Cape Galata, on the S. of the bay, stands a lighthouse. In 1873 there entered the port 659 vessels of 216,963 tons, and cleared 655 of 216,303 tons. The exports in the same year (cereals and live-stock, including 30,067 sheep) amounted to 13,426,850 fr., and the imports (manufactured goods and colonial produce) to 11,179,272 fr. Pop. 10,000, mostly Greeks and Bulgarians. Near V. the Turks defeated the Hungarians with great slaughter, 10th November 1444. The Russians took it in 1828, and the French and English Allies encamped here for four months before sailing for the Crimea in September 1854. V. was included in Bulgaria by the Berlin Treaty, in terms of which it is to be dismantled along with the other forts of the principality. After the conclusion of the definitive Russo-Turkish treaty in February 1879, V. was a chief port for the embarkation of the Russian troops.

Varnha'gen von Ense, Karl August, born at Düsseldorf, 21st February 1785, passed his boyhood at Hamburg, where his father practised as a medical man. He studied medicine himself, but with it philosophy and ancient literature, at Berlin hearing Fichte and A. von Schlegel, at Halle Schleiermacher, Wolf, and Steffens. With Chamisso he edited a *Musenalmanach* in 1803, the year of his meeting Rahel, with whom, on removing to Tübingen in 1808, he maintained by voluminous letters the friendship of the past five years. Entering the Austrian army (1809), he was wounded at Wagram, and visited Paris as Bentheim's adjutant in 1810; but in 1812, on Austria's joining in the Russian campaign, quitted her service, and next year accepted a captain's commission in that of Russia. Exchanging a career of arms for that of Prussian diplomatist, he married Rahel, 27th September 1814, and having attended the chancellor Hardenberg to the Vienna Congress, and thence to Paris (1815), settled at Karlsruhe as resident minister. In 1819, however, a variance with his government recalled him to Berlin, where, busy with literature and bearing the empty title of *Geheim-Legationsrath*, he chiefly resided down to his death there, 10th October 1858. A graceful poet of the Romantic school, a subtle critic, and masterly biographer, V. ranks with the first prose-writers of Germany for polish and style, so polished indeed as sometimes to lose all character, while its matter is often marred by a narrow misanthropy, engendered by his exclusion from public life. Chief of his manifold works are *Deutsche Erzählungen* (1815), *Vermischte Gedichte* (1816), *Goethe in den Zeugnissen der Mitlebenden* (1823), *Biographische Denkmale* (5 vols. 1824-30), and *Denkwürdigkeiten und Vermischte Schriften* (9 vols. 1843-59). Over twenty volumes of diaries and correspondence have been published from his posthumous papers, and his *Ausgewählte Schriften* (Leip. 1871-77) fill nineteen more.—V.'s wife, **Rahel Antonie Friederike Levin**, the daughter of a Jewish merchant, was born at Berlin in June 1771. Ill-health, and love affairs made hopeless by the stigma of her birth, saddened her earlier years, though hers was brightest of all the Jewish *salons*, the focus then of Berlin's intellect. Courted by all the chief authors, artists, and statesmen of those disordered times, she exercised by her broad sympathies and liberal culture a lively influence on the German mind; but in 1806 she left Berlin to wander awhile in France and Germany. The death of Marwitz at the battle of Montmirail (1813) removed V.'s rival in her affections; and Rahel, turning a Christian less from conviction than convenience, entered upon a union of pure and singular happiness, closed by her death at Berlin, 7th March 1833. V. published *Rahel, ein Buch des Andenkens für ihre Freunde, Briefe enthaltend* (2d ed. 3 vols. 1834), and *Gallerie von Bildnissen aus Rahels Umgang und Briefwechsel* (2 vols. 1836), since which has appeared her correspondence with David

Veit (2 vols. 1861) and with V. himself (6 vols. 1874–75). See also Schmidt-Weissenfels, *Rahel und ihre Zeit* (1857); L. Assing, *Aus Rahels Herzensleben* (1877); Carlyle, 'Rahel and V.' in vol. vi. of his *Collected Works;* and Mrs. Jennings, *Rahel, her Life and Letters* (Lond. 1876).

Var'nish is a clear transparent solution of some resinous substance, which when spread in thin coatings over any body dries and hardens, forming a smooth glossy surface impervious to air, and unaffected by moisture. V. is therefore an important substance for at once giving lustre and gloss, and for preserving the substance of paintings, painted work, woodwork, maps, plans, and to some extent metallic surfaces, &c. The resinous bodies chiefly used for varnishes are copal, animé, lac, elemi, mastic, sandarach, and amber, which may be coloured with such substances as anatto, gamboge, saffron, aloes, turmeric, or dragon's blood. The solvents with which these substances are made into varnishes are either drying oils, with which oil V. is made, or alcohol about 67° over proof, giving spirit V. Spirit V. is prepared by dissolving the resinous material under the influence of heat in methylated spirit of the strength above indicated, care being taken to prevent loss by evaporation. Oil V. is commonly prepared with the finest boiled linseed oil, which is added hot to the resin previously molten by heat, and to this hot spirit of turpentine is added. As an example of proportions used, the following recipe for body V. may be given:—Pure copal, 8 lbs.; boiled oil, 2 gallons; spirit of turpentine, 3½ gallons. This, when prepared as indicated, strained and cooled, forms a hard, clear, and durable V. See Bersch, *Fabrikation der Mineral und Lack-farben* (Vein. 1878).

Var'nish Tree, a name applied to several trees yielding a juice from which a varnish is prepared in different countries. Many of these trees belong to the natural order *Anacardiaceæ*, and the most important have already been mentioned under Melanorrhœa and Sumach. Another, named Sylhet V. T. (*Semecarpus Anacardium*), furnishes a black varnish much used in India, and its juice, mixed with lime-water, serves for marking cotton. New Granada V. T. is *Elæagia utilis*, belonging to *Rubiaceæ*. In this the resinous matter from which the varnish is prepared is secreted by the stipules which invest the unexpanded buds.

Varr'o, Mar'cus Teren'tius, 'the most learned of the Romans,' a title which he merited by his vast and various knowledge, was born at Reate, B.C. 116. His education was superintended by the knight Præconius and the philosopher Antiochus. He engaged in public life, and espoused the cause of Pompey, but after the battle of Pharsalia (B.C. 48) he submitted to Cæsar, who appointed him keeper of his library. Under the second triumvirate he was proscribed, along with his friend Cicero; but, unlike the great orator, he escaped with his life. He afterwards obtained the favour of Octavianus, and passed the remainder of his days in uninterrupted literary labours. He died B.C. 28. V. wrote a large number of books on a great variety of subjects. Of the majority of these we only know the names. The chief are—1. *De Re Rustica*, a methodical treatise on agriculture, in three books, of which the third alone is extant. 2. *De Lingua Latina*, a philological dissertation, in 24 books, of which 6 (5–10) remain. This work contains much curious and valuable information, ingenious conjecture, and wild theorising. 3. *Sententiæ*, a collection of pithy and proverbial sayings excepted from the works of V. 4. *Antiquitatum Libri*, consisting of (1) *Human Antiquities*, in 25 books, an account of the creation, constitution, and early history of man, and (2) *Divine Antiquities*, in 16 books, 'a complete account of the mythology and rites of the inhabitants of Italy from the most remote epoch.' We only possess a few fragments of this treatise. In addition V. wrote satires and works on history, biography, philosophy, geography, and mathematics, which we know only from notices by other writers. See Roth's *V.* (Basel 1857), and Boissier's *Essai sur la vie et les ouvrages de Varron* (Par. 1861).

Varu'na ('the investing,' from the same root as the Gr. *ouranos*), one of the earliest gods of the primitive Sanskrit mythology, whose image is still worshipped in Hindu temples. Though originally the god of heaven and of day, he has now come to be regarded as the deity that presides over the ocean—the waters which have left the air and rest on the earth. See Dr. A. Hillebrandt, *V. und Mitra* (Breslau 1877).

Va'rus, Pub'lius Quintil'ius, was consul (13 B.C.), acquired enormous wealth as proconsul of Syria (6 B.C.), where he suppressed a rising of the Jews. Entrusted with the command of the Roman forces in Germany (6 A.D.), he was leading three legions through a pass in the Teutoburger Wald, when Hermann (q. v.) fell on him with a barbarian host, and after a three days' conflict annihilated the Roman troops. V. himself committed suicide. Suetonius (*Aug.* cap. 23) tells us that Augustus was overwhelmed by the news of the disaster, and in his grief called on the dead man to give him back his legions.

Va'sa, a family which held the throne of Sweden (q. v.) from 1523 to 1654 in the persons of Gustaf I. (q. v.), Erik XIV. (q. v.), Johan III. (1568–92), Sigismund (q. v.), Karl IX. (q. v.), Gustaf II. Adolf (q. v.), and Queen Christina (q. v.). The name of V. has in recent times been claimed by the son of the deposed king Gustaf IV. Adolf (q. v.), Prince Gustaf of Holstein-Gottorp, who was born in 1799, and died at Pillnitz, August 4, 1877.

Vas'arhely or **Hod'mező-Vas'arhely**, a town of Hungary, in a marshy plain near the left bank of the Theiss, 94 miles S.W. of Grosswardein by rail, with an active trade in tobacco and live stock. Pop. (1870) 49,153.—**Maros-V.**, a town of Hungary, capital of the Szekler district in Transylvania, on the Maros, an affluent of the Theiss, 37¼ miles E.N.E. of Kocsard by rail, with a strong castle, a library of 60,000 volumes (founded by Count Tökely), and a large trade in tobacco, wine, and fruits, the produce of the surrounding country. Pop. (1870) 12,678.

Vasa'ri, Giorgio, an Italian painter, architect, and author, was born at Arezzo in 1512. He studied under Michael Angelo, and was employed by various members of the Medici family in the superintendence and decoration of their buildings. He died at Florence, 27th June 1574. The Uffizi at Florence and the Abbadia at Arezzo are reckoned his achitectural masterpieces, and his 'Last Supper' at Arezzo, and his portraits of Cosmo I. and Lorenzo de Medici, are mentioned as favourable specimens of his pencil. But it is by his literary labours that he has made his name a household word to all time wherever the smallest interest is felt in the history of modern art. His *Vite dei più eccellenti pittori, scultori ed architetti* was the first important work on the subject, and however grievous are its omissions and mistakes, it has a freshness and naïveté that will always secure it a place in the history of art. It first appeared in 1550, and again enlarged in 1568. Among subsequent editions of the original, Bottari's (Rome 1759), Della Valle's (Siena 1791), Montani and Masselli's (Flor. 1832–38), and Le Monnier's (15 vols. Flor. 1846–57) rank high; but they will probably be superseded by that undertaken by Puri and Milanesi (8 vols. Milan 1878, *et seq.*). Milanesi has already published a volume of selected lives (3d ed. 1878). The complete work is translated into German by E. Forster and Schorn (Stutt. 1832–38), into French by Jeanron and Leclanché (Paris, 10 vols. 1840–42), and into English by Mrs. Jonathan Foster (Lond. 1850; 5 vols. *Bohn's Standard Library*).

Vas'co da Ga'ma. See GAMA.

Vascular'es, or **Cotyle'doneæ**, are names of one of the great divisions in De Candolle's natural system, embracing all flowering plants, thus standing in opposition to his Cellulares or Acotyledoneæ.

Vas'cular Tiss'ue, the *vessels* or *ducts* of plants, so called from the mistaken notion that their functions are analogous to those of the vessels (veins and arteries) of animals. A *vessel* consists of a vertical row of cells, which have their transverse partition-walls obliterated, so as to form a continuous tube. As all flowering plants, as well as ferns and a few other cryptogams, have vessels, and are therefore called *vascular plants*, so the majority of cryptogams having only cellular tissue are termed *cellular plants*. Vessels have their sides very variously marked; some, called *spiral vessels*, have a spiral fibre coiled in their inside which unrolls when the vessel is broken; others are marked with longitudinal slits, cross bars, minute dots or pits, or with transverse rings.

Vase (Lat. *vas*), a term anciently applied to a vessel used at sacred or public ceremonies, or for domestic purposes, but now applied to a vessel used for ornament. All nations, ancient and modern, that have cultivated the arts, have displayed a taste for elegant and costly vases. The Egyptians, Greeks, and Romans

fashioned them from precious and other stones, bronze, silver, gold, ivory, and glass, as well as from clay, the material that was first employed. Greek vases of painted earthenware—numerous examples of which have been recovered from tombs within the last 150 years —display the perfection of form and artistic treatment; and in so far as the painted subjects have shed light upon the history, mythology, religious, civil, and domestic customs of that nation, they have proved of great value to antiquaries. These vases present a great variety of forms, always elegant, but in each case subordinated to usefulness. Those of the best period have figure subjects painted in a reddish colour, relieved by white, on a dark or black ground; while the archaic vases are small, with dark figures on the natural ground of the clay. The Romans formed their vases mostly on Greek models, and for excellence in variegated glass they have never been approached. The Portland V. (q. v.) and the 'Naples' V. in the Museo Borbonico at Naples are splendid examples of the remarkable artistic skill attained in sculptured cameo glass. The famed *vasa diatreta*, with an almost detached reticulated pattern, were worked out of the solid glass. Murrhine vases (*vasa murrhina*), which were first brought by Pompey to Rome from the East, were enormously valued. Nero, it is said, paid one million sestertii for a murrhine goblet. The material of these murrhine vases has not been precisely determined; most probably it was a kind of agate displaying red and purple colours, perhaps obtained artificially by heat, as is practised in India and Germany at the present time. Bronze was a favourite material for vases with the Romans, and one of the finest specimens of antique art is the 'Warwick' V., of marble, which was found at Tivoli, and is now in Warwick Castle. It is well known from its bronze electrotypes. Italy, France, and Germany, produced in the 16th and 17th centuries many vases in sculptured and enamelled gold-work, rock crystal, and other hard stones, which are the perfection of artistic form and execution; and in the 15th and following centuries the masterpieces of glass art (see GLASS), in the form of vases, &c., were issued from the manufactories of Venice. See Sir W. Hamilton, *Engravings of Ancient Vases* (Naples, 1791-95); Millin, *Peintures de Vases Antiques* (1818); Gerhard (E.), *Auserlesne Griechische Vasenbilder* (Berl. 1839-58); and *Die Griechischen Vasen in ihrem Formen- und Decorationssystem*, by Lau, Brunn, and Krell (Leip. 1877).

Vas'eline, a name given by Americans to a new commercial product obtained from petroleum after the lighter hydrocarbons are driven off, and composed of a mixture of paraffins. It is a pale yellow, translucent, semi-solid, crystalline body without taste or smell, does not become rancid, resists the action of most chemicals, is soluble in ether, not so in water or alcohol; and it is now widely employed as a base for ointments, pomades, cold cream, &c. V. is also useful for coating surgical instruments and steel surfaces generally to protect them from rust.

Va'so-Mo'tor Sys'tem, the name given to those nerve-filaments derived from the *Sympathetic system* of nerves (see NERVE and SYMPATHETIC SYSTEM), and which are distributed to the walls of the arteries. The V.-M. nerves thus exercise a very direct influence on the blood-circulation, and appear to originate in the grey matter of the *medulla oblongata*. Division of the V.-M. nerves of the abdominal blood-vessels causes dilatation, and effects comparable to those following severe internal hæmorrhage.

Vass'al (Fr., probably from Welsh *gwas-awl*, 'serving'), in Feudal terminology the correlative of Suzerain (q. v.), the V. being the holder of a fief from a superior lord. See FEUDALISM.

Vass'ar Coll'ege, 2 miles E. of Poughkeepsie, New York, was founded in 1861 by Matthew Vassar (1792-1868) for higher female education. A fine brick edifice, 500 feet long by 200 wide, it was erected at a cost of $200,000, and opened in 1865, its studies embracing the regular course of first-rate colleges, and the students receiving B.A. and M.A. degrees. In 1876 V. C. had a president and lady-principal, 9 professors (6 male) and 22 female teachers, 202 collegiate and 168 preparatory students, and 328 alumni.

Vassilkov', a town of Russia, government of Kiev, on the Stugna, an affluent of the Dnieper, 18 miles S.S.W. of Kiev. It has active manufactures of tobacco, soap, and tallow-candles, and a large trade in corn, cattle, and horses. Pop. (*St. Petersb. Cal.* 1878) 16,597.

Vas'to, a town of Italy, province of Chieti, on the slopes of a hill overlooking the Adriatic, 131 miles S.E. of Ancona by rail. Its cathedral has a Gothic façade, and in the town-hall is a small museum of relics and inscriptions. V. has trade in wine, vinegar, and oil. Pop. (1874) 13,797.

Vat'ican, The, the most extensive palace in the world, and, as the residence of the Pope, and the storehouse of valuable literary and art collections, one of the chief attractions of modern Rome. A building of the kind was erected on the Mons Vaticanus by Pope Symmachus about the year 300, near the anterior court of old St. Peter's, and it was rebuilt by Eugene III. and enlarged by Nicholas III. The V. did not, however, supersede the Lateran (q. v.) as the usual residence of the popes till their return from Avignon in 1377. The first conclave, held in 1378, resulted in the so-called Western Schism (see SCHISM). In 1450 Nicholas V., with the object of making the V. the most imposing of palaces, began the work of combining with it the residences and offices of the cardinals, and the small portion completed by him, afterwards occupied by Alexander VI., and named Tor di Borgia, was extended by subsequent popes. The Sixtine Chapel was erected by Sixtus IV. in 1473, and the Belvedere or garden-house by Innocent VIII. in 1490. Bramante (q. v.), under Julius II., united the latter with the palace by means of a great court, and constructed the Loggie round the Cortile die S. Damaso. By the erection of the library Sixtus V. divided Bramante's great court into two parts, the anterior court and Giardino della Pigna. The Pauline Chapel was the work of Paul III. (1534), and the present residence of the popes was completed by Clement VIII. (1592-1605). The labour of extending and adorning the V. was continued by Urban VIII., Pius VII., and Gregory XVI.; and even Pius IX., amid the revolutionary struggles of the 19th c., found time to enclose the fourth side of the Cortile di Damaso by reconstructing the great staircase forming the approach from the colonnade of St. Peter's. The palace now comprises 20 courts and some 11,000 halls, chapels, saloons, and private apartments. Chief among its great art-treasures are the Sistine frescoes of Michael Angelo and Raphael's Stanze and Loggie. The picture-gallery is one of the richest in Rome, and the collection of antiquities is the finest in the world, including extensive Egyptian and Etruscan museums, and comprising among its classical sculptures the Torso of Hercules, the Laocoon, and the Apollo Belvedere. The library now contains nearly 24,000 MSS., of which 17,400 are Latin, 3450 Greek, and 2000 Oriental; it also contains about 50,000 printed books, but of these only what formerly constituted the library of Cardinal Mai is catalogued and available for consultation. The archives are specially rich in documents relating to the Middle Ages, and comprise registers of the papal acts, letters of popes from Innocent III. down to Sixtus V. in 2016 vols., correspondence with nuncios and foreign nations, &c. The privilege of studying in the art galleries, curtailed since 1870, was extended by Leo XIII. in December 1878.

Vat'ican Coun'cil, the nineteenth œcumenical council of the Catholic Church, assembled at Rome, 8th December 1869, 719 prelates out of the 1037 invited having answered the summons of Pope Pius IX., and of this number 276 were Italians. Its decrees on the 'dogmatic constitution of the Catholic faith,' aimed at rationalism, were unanimously adopted, 24th April; but those on the 'dogmatic constitution of the Church of Christ,' *i.e.*, the decrees of Infallibility (q. v.), received (13th July) only 400 'placets,' against 60 'placets' *juxta modum*, and 88 'non-placets,' the last including Cardinals Rauscher, Schwarzenburg, and Mathieu, with Bishops Dupanloup, Strossmayer, and Hefele. On July 18, 110 recalcitrant prelates stayed away, and thus the Infallibility became a dogma by 533 affirmative against 2 dissentient votes. The council, having achieved its principal object, was indefinitely postponed, 20th October 1870, owing to the outbreak of the Franco-German War. See ROMAN CATHOLIC CHURCH; the recent works of Manning (q. v.), Newman (q. v.), and Gladstone (q. v.); and J. Friedrich, *Geschichte des Vaticanischen Konzils* (Bonn 1877).

Vattel', **Emmerich de**, a French jurist, was born August 25, 1714, at Couvet in Neuchâtel. Having studied at Basel and Geneva, and published a *Défense du Système de Leibnitz*

(Leyden 1741), he sought employment at the Prussian court; but his application being less successful than he had hoped, he removed to Dresden, and there he ultimately obtained a pension, was appointed the Elector's ambassador to the republic of Bern, and attained the rank of privy councillor. He died at Neuchatel, December 27, 1767. The work by which his name is best preserved is *Droit des Gens; ou Principes de la Loi naturelle appliqués à la Conduite et aux Affaires des Nations et des Souverains* (Neuchatel 1758, 2 vols.), being an exposition in the main of the doctrines of the great German jurist Wolff. It has been edited by Royer-Collard (2 vols. Par. 1830), by Chambrier d'Oleires (2 vols. Par. 1839), and by Pradier-Fodéré (3 vols. Par. 1863). Among the author's minor efforts are *Loisirs Philosophiques* (Dresden 1747); *Polyergie ou Mélanges de Littérature* (Par. 1757); *Amusemens de Littérature, de Morale, et de Politique* (Hague, 1765).

Vau'ban, Sébas'tian le Prestre de, Marshal of France, and the great military engineer of the *grand siècle*, was born, 15th May 1633, at St. Léger de Fougeret, Burgundy, of a noble but impoverished family. Left an orphan at an early age, he was educated by the curé of his village, from whom he received the only instruction in mathematics and mensuration he ever had. In 1651, at the age of seventeen, he joined the army of Condé, then in revolt against the royal authority, and soon distinguished himself by his gallantry as well as his marked turn for engineering. Taken prisoner, he was easily persuaded by Cardinal Mazarin to enter the royal service, and was appointed to a lieutenancy. In 1655 he received a commission placing him in the corps of engineers. From this date his fame rapidly and steadily increased. Under the command of Turenne, he directed the sieges of Landrecies, Condé, St. Ghislain, Mardyk, Gravelines, Oudenarde, and Ypres, and was rewarded by rapid advancement in the service. It is impossible to follow him through all his campaigns, and his more peaceful labours of defensive fortification. It has been calculated that V., in the course of his career, conducted 53 sieges, took part in 140 actions, constructed 33 new fortifications, and reconstructed the fortifications of 300 places. In many sieges he acted under the personal command of Louis XIV., whom he managed with much address, though without flattery or sycophancy. He was uniformly humane, regarding it as the duty of a general to avoid all useless expenditure of human life. Two great advances in the art of besieging attributed to V. are the use of *parallels*, which, if he did not invent, he developed and perfected, and the system of *ricochet firing* which he invented. The former he introduced at the siege of Maestricht in 1673, and the latter at the siege of Ath in 1697. He it was who carried out the gigantic system of frontier fortification, which so impoverished the treasury of Louis XIV., its cost being estimated by some at as much as £45,000,000, while others reduce it to about £8,000,000. It may be doubted, however, whether he himself approved this immense strategical and financial blunder. In 1676 he obtained the rank of lieutenant-general, and in 1703 was made Marshal of France. Towards the close of his life he occupied himself largely with political and politico-economical questions. He had the courage to present memorials both to Louvois and Madame de Maintenon recommending a restoration of the Edict of Nantes, and in 1689 he demonstrated the necessity of fortifying Paris. In a collection of fugitive pieces published under the title of *Oisivetés de M. de V.* (Par. 1843-46), he treats of both military and economical subjects, being among the first to recognise the importance of statistics in such inquiries. His treatise, called *Projet d'une Dîme Royale*, embodying proposals for reforms in government and taxation, conceived in the most liberal and progressive spirit, drew upon him the displeasure of the king, and very shortly afterwards he died at Paris, March 30th, 1707. His *Œuvres Militaires* were collected and published at Paris in 1796. See Carnot and Fontenelle, *Éloges*; Chambray, *Notice Historique sur V.* (Par. 1845); Poncelet's *Mémoire*, consisting of extracts from V.'s unpublished papers (Par. 1841-43), and above all G. Michel's *Histoire de V.* (Par. 1879).

Vaucluse', a department in the S.E. of France, bounded N. by Drôme, E. by Basses Alpes, and separated S. from Bouches du Rhône by the river Durance, and W. from Gard by the Rhone. Area, 1370 sq. miles; pop. (1876) 255,703. By the chain of Ventoux (6273 feet high) in the N.E., the Luberon Mountains (5656 feet) in the S.E., and the intervening V. Mountains (2132 feet), it is divided into three great basins, that of Orange in the N., that of Cavaillon in the S., and that from Avignon to Carpentras in the middle. The Rhone, with its tributaries, the Lez, Aigues, Louvèze, and Nesque, and the Durance with its affluent the Calavon and its great system of canals, abundantly water the soil, which is fertile, and favourable to the cultivation of the olive and the vine. Oats, maize, millet, potatoes, madder, and teasel are largely grown and exported. In 1875, 68,530 metrical quintals of coal were raised. The cultivation of the vine and the rearing of the silkworm are the principal occupations in the rural districts, but, in the towns, paper, chemicals, leather, pottery, soap, wax candles, hats, brandy, beer, liquorice, and confections are extensively manufactured.—The village of V. (Lat. *Vallis clausa*), from which the department takes its name, situated in a romantic, rocky valley in the V. chain, 18 miles E. of Avignon, is famous from having been the residence of Petrarch, who has celebrated its beauty in his sonnets. Near it is the fountain of V., the source of the Sorgues, a favourite haunt of the same poet, to whom a monument was erected here in 1809.

Vaud, Pays de (Ger. *Waadt, Waadtland*), a canton of Switzerland, surrounded by the cantons of Neufchâtel, Freiburg, Bern, and Valais, the Lake of Geneva, the canton of Geneva, and France. Area, 1244 sq. miles; pop. (1876) 244,352. It is a table-land between the Jura and the Bernese Alps, whose highest point in V. is Diableretz (10,663 feet high). It is crossed by Mount Jorat, which parts the basins of the Lakes of Geneva and Neufchâtel. The chief rivers are the Rhône, Saane, Orbe, and Broye. Cattle-rearing and the cultivation of fruit, vine, tobacco, flax, and hemp are the chief occupations. Watches, musical boxes, tobacco, and leather are manufactured. V. was taken in 1536 from Savoy by the canton of Berne, but freed itself in 1798, and in 1803 became an independent member of the Swiss Confederation. The present democratic constitution dates from December 15, 1861.

Vaude'ville, a word derived from Vaux de Vire, a village in Normandy, where Basselin composed a number of popular satirical songs. The term formerly meant a song of a lively turn and often of a topical nature, containing several couplets and a refrain; and from the introduction of such songs into theatrical pieces it has now come to signify a sparkling comedietta, interspersed with lyrics incidental to the story. The V. forms a favourite class of entertainment on the French stage.

Vau'dois. See WALDENSES.

Vaughan, Charles John, D.D., was born at Leicester in England, in 1810. From Rugby, where he was a pupil of Dr. Arnold's, he passed to Trinity College, Cambridge, graduated B.A. in 1838, became a fellow in 1839, and proceeded M.A. in 1841. As Chancellor's classical medallist he was in 1838 bracketed with Lord Lyttleton. In 1841 he became vicar of St. Martin's, Leicester, and from 1844 to 1859 was head-master of Harrow School, was appointed vicar of Doncaster, and in 1869 succeeded Dr. Robinson as Master of the Temple. In 1879 he accepted the deanery of Landaff. Dr. V. stands in high esteem for his fine spirit, his tireless activity, and his generous devotion to all the duties of his profession. Of the forty or fifty volumes which he has published, it is enough to name *The Personality of the Tempter and Other Sermons* (1851), *Epiphany, Lent, and Easter* (1860), *Epistle to the Romans, with Notes* (1861), *Lectures on the Philippians* (1862), *Christ the Light of the World* (1866), *Last Words in the Parish Church of Doncaster* (1869), *Half Hours in the Temple Church* (1871).

Vaughan, Henry, an English poet, distinguished by the self-adopted title of the 'Silurist' (*i.e.*, the Silurian, or native of South Wales), was born at Newton, near Skethrock, about 5 miles from Brecon, in the year 1621-22. Along with his twin brother Thomas he entered Jesus College, Oxford, in 1638. Their university course was disturbed by the Civil War; both were through family tradition keen royalists. Thomas at least took part in the conflict as a combatant, and Henry was sufficiently prominent to be imprisoned by the Parliamentarians. From Oxford Henry appears to have proceeded to London, and it was there that his first volume appeared in 1646—*Poems, with the Tenth Satyre of Juvenal Englished, by Henry Vaughan, Gent. Printed for G. Badger.* We next find him practising medicine at Brecon; and in 1647 he settled down at Skethrock as village doctor. Of his after life little is known except by inference. He appears to have suffered from serious illness and a 'peevish, inconstant state of health;'

and if Mr. Grosart's conjecture be right, he was bereaved of a youthful and deeply-loved wife. The religious instincts of his nature became so exceptionally developed that he regretted the innocent secularism of his early poems, and though he published four volumes of devotional pieces—*Silex Scintillans* (1650), *Mount of Olives* (1652), *Flores Solitudinis* (1654), and *Silex Scintillans, Part II.* (1655)—he left his profaner productions to their fate. Of these, however, one collection was made by his Oxford friends, *Olor Iscanus* (*i.e.*, the Swan of Usk, 1651), and another by his brother, *Thalia Rediviva* (1678). He survived till April 23, 1695. H. V. ranks high as a religious poet, and even to a purely secular reader he is not 'all stone and earth,' but, to use his own quaint phraseology, 'has shoots of everlastingness.' An avowed disciple of George Herbert, he indulges in similar conceits and perpetrates similar uncouthnesses, but none the less attains from time to time much beauty and charm both of thought and diction. His *Retreat*, for example, is no unworthy prototype of Wordsworth's *Intimations of Immortality.* A complete edition of V.'s works, both in prose and verse, occupies four volumes of Mr. Grosart's Fuller Worthies' Library (privately printed, 1871). A collection of his poems was published by the Rev. H. F. Lyte (1847), and reprinted by Bell & Daldy (1858).

Vaughan, Robert, D.D., was born in Wales in 1795, and received his theological education at Bristol College. After discharging the pastoral office for six years at Worcester, he was called in 1825 to an Independent Chapel in Kensington. From 1830 to 1842 he was professor of history in London University (now University College), and in 1842, on the removal of the Lancashire Independent College from Blackburn to Manchester, he was called to the presidency. Owing to failing health he resigned the post in 1857. He died at Torquay, June 15, 1868. V. was the principal projector of the *British Quarterly Review*, and editor from its commencement in 1845 till 1866. His principal works are *John de Wycliffe, D.D., a Monograph* (1853), previously published as *Life and Opinions of John de Wycliffe* (2 vols. 1828), *The Protectorate of Oliver Cromwell* (2 vols. 1838), *Essays on History, Philosophy, and Theology* (2 vols. 1849), *The Age and Christianity* (1849), and *Revolutions in English History* (3 vols. 1852-63). A pathetic interest attaches to his Memoir of his son, Robert Alfred Vaughan, originally prefixed to *Essays and Remains* (2 vols. 1858), and afterwards published separately in 1864. **Robert Alfred V.** was a young man of rare promise and attainment, who died in 1857 at the age of thirty-two. Of the literary power that was in him he has left proof in *The Witch of Endor and other Poems* (1844), and *Hours with the Mystics* (2d ed. 1860). See *Robert V., a Memorial* (Lond. 1869), and J. G. Rogers' *Pulpit Memorials* (Lond. 1878).

Vault (Old Fr. *volte;* from Med. Lat. *voluta*, 'something rolled'), in architecture, an extended arch; an apartment or a passage having an arched roof of stone or brickwork. There are several forms of vaults. A *cylindric, barrel*, or *wagon-headed* V. has a uniformly hemispherical concave surface; a *pointed* V. implies the use in construction of the pointed arch; and a *groined* V. is formed by the intersection of several vaults crossing each other at right angles. Barrel and pointed vaulting have been discovered in Egyptian tombs and Assyrian drains; and spherical or domical (see DOME) and groined as well as barrel vaults were constructed by the Romans. They introduced a groined V. formed by the intersection of two semi-cylinders of equal span; hence it is distinguished as *Roman vaulting.* Vigorous expression of strength is given to Norman vaulting by the introduction of massive *transverse* ribs (Fr. *arcs doubleaux*) on barrel vaults and *diagonal* ribs (Fr. *ogives*, from Lat. *augire*, 'to strengthen') on the groins of intersecting vaults; in late examples the ribs are decorated with zigzags and other ornaments. The pointed arch and groined V. are seen to perfection in Gothic architecture. Ribs run along the *ridges* of the main and cross vaults, in the Early English style, and *secondary diagonals*, and numerous small ribbings termed *liernes* (Fr. *lier*, 'to bind'), are found on Decorated and Perpendicular vaulted ceilings, which have a rich appearance of network. Ribs are exquisitely moulded and cusped, and pendants are not uncommon in Perpendicular vaults; and to the end of that style belongs the beautiful, exclusively English, form of vaulting, known as *Fan-Tracery* (q. v.).

Vault'ing Shaft, a pillar or shaft which rises from the ground, the capital of a pier or a corbel, and from which spring the ribs of a Gothic vault.

Vauque'lin de la Fres'naye, Jean, a French poet, born in 1535 at the château of La Fresnaye near Falaise, at the age of eleven composed *Foresteries* (Poit. 1555), a pastoral poem. He passed some years of nominal legal study at Poitiers, Paris, and Bourges, and was wounded at the siege of Saint-Lô, fighting with Matignon against the Huguenots. Henri III. appointed him lieutenant-general, and Henri IV. president, of Caen, where he died in 1607. V.'s *Œuvres* (Caen, 1605-12), graceful though frequently obscure, include the earliest French *Idillies* ('Idyls'), some sacred and political sonnets, and *Art poëtique, Satires*, &c. See J. Travers, *Essai sur la Vie et les Œuvres de V.* (Caen 1872).

Vauxhall' Gar'dens, a famous old London resort of pleasure, named from the manor of Vauxhall (Fulke's Hall), in which they were situated, the locality being in Lambeth, opposite Millbank. The New Spring Gardens, opened in May 1660, were, according to Pepys, 'mighty devertising.' They became very popular, to judge from Wycherley's allusions in 1672 and the comments of the *Spectator* in 1711. In 1732 they were opened by Jonathan Tyers for a 'ridotto al fresco,' and in 1833, their most successful season, they were visited by 133,279 persons, and the receipts amounted to £29,590. As many as 20,137 visitors attended on the single night of 2d August 1833. V. G. were closed in 1859, but their fun and follies live on in the pages of Thackeray's *Vanity Fair.*

Vav'asour (Fr. *vas-vassor*, by Pott derived from *vassus vassarum*, and so ultimately from the Cymr. *gwas-awl*, 'serving'), in the feudal system of the Continent, a vassal who held immediately of the higher nobility. In England the title was rarely used, though Camden defines it as next to Baron, while Chaucer applies it to his 'Frankeleyn,'—

'A shirreve hadde he ben and a counter,
Was nowher such a worthi *vavaser*.'

Vec'tor, in mathematics, is any directed quantity, and was first introduced as a fundamental conception clearly distinguished from that of mere magnitude by Sir W. R. Hamilton of Dublin in his calculus of Quaternions (q. v.). The simplest manner in which to represent such a quantity which involves both direction and magnitude is by means of a straight line in space; then the V. may be regarded as a *stepping* from one extremity of the line to the other. It then follows as an immediate consequence that, if we take any three points, A, B, and C, the step from A to C is equivalent to the step from A to B and the step from B to C taken in succession, a truth which is expressed in quaternion language thus—the V. AC is equal to the sum of the vectors AB and BC. The addition of vectors is therefore exactly the same process that has long been recognised in the composition of velocities and forces.

Ve'da (from the Sansk. *vid*, 'to know:' comp. Gr. *oida*, Lat. *videre*, Eng. *wit*), the term applied to the sacred books of the Hindus, or rather to that most ancient portion of them which is directly concerned with religious worship, being co-extensive with *Sruti* or revealed religion. The Vedas proper consist of four collections of hymns, (1) the Rig-V.; (2) the Yagur-V., subdivided into the Taittiriya and the Vajasaneyin; (3) the Sama-V.; and (4) the Atharva-V. Of these, the three last contain little more than extracts from the first, with a commentary that is admitted to be of comparatively recent date. They are of little interest to any but the professional Sanskrit scholar; but the Rig-V. deserves the attention of all cultivated persons, not only as being one of the most ancient books in the world, but also as representing the primitive forms of faith held by the common ancestors of the Aryan stock. The prefix 'Rig' (derived from the root *ric* or *rich*) means praise or celebration. Like the other three, the Rig-V. is divided into two distinct portions: a *sanhita* or collection of *mantras* or hymns of praise, and a *Brahmana* or code of *sutras* or ritualistic precepts. Of these again, the *mantras* are evidently by far the most ancient; and it is with them that this article will chiefly deal.

According to orthodox Hindu theory, all the Vedas alike are held to have been revealed, through sight no less than by hearing, to certain holy men called Rishis, who transmitted their divine knowledge by constant oral repetition to a succession of disciples.

Even at the present day few MSS. exist, and these of no great age or authority; in cases of disputed authenticity the regular appeal is to the memory of the *pandits* of greatest repute. Tradition relates that the existing recension is due to a mythical personage named Vyasa, who is also credited with the composition of the Hindu epics. It is only by the methods of modern criticism that we are enabled to assign even an approximate date to the composition of the Rig-V. Sanskrit literature itself is totally destitute of the historical sense. Internal evidence, based upon a comparison of the older with the later portions, and corroborated by such independent facts as the dispersion of the Aryan race and the historical rise of Buddhism, leads to the conclusion now generally accepted that the *mantras* of the Rig-V. were composed by a succession of poets between the 15th and 12th centuries B.C. Their general purport is praise of the personified elements of nature, combined with moral reflections. The chief gods addressed are Agni, or fire; Indra, or the watery atmosphere; Varuna, or the sky; Surya, or the sun; Ushas, or the dawn; and Maruts, or the storms. All of these are invoked to protect their worshippers from evil, and to grant them earthly blessings. But, according to Max Müller, the several deities are not regarded as supreme each in his own domain, but every one is in turn identified with the one omnipotent Divinity everywhere to be recognised amid the forces of nature. To this form of belief, midway between Polytheism and Monotheism, Max Muller has given the name of Kathenotheism. It is important to observe that, on the one hand, the state of society, as pictured in the Vedas, is one raised far above the pastoral or nomad stage, and that, on the other hand, it is entirely free from the characteristic corruptions of modern Hinduism. The Hindus of the Vedic period are not only acquainted with agriculture and many of the handicrafts of civilisation, but they live in walled cities subject to mighty monarchs. The existence of an hereditary priesthood, the exclusiveness of caste, the self-immolation of widows, child-marriage, refusal to eat cows' flesh, repugnance to cross the sea—are all alike unknown to them. The doctrine of metempsychosis, or transmigration of souls, is not found; but a belief in personal immortality is distinctly traceable. The necessity of sacrifice is inculcated from the first. But in the primitive *mantras* sacrifice takes the simple form of offerings of clarified butter and the mystic juice of the *soma* plant, in order that the gods may therewith be nourished and exhilarated. It is only in the later Brahmana, which may perhaps be ascribed to the 7th c. B.C., that expiatory sacrifices come to be regarded as the sum total of religious duty. Ritualistic observance and punctilious attention to ceremonial now take the place of the simple worship and praise of the earlier period; and with these corruptions the priests or Brahmins gradually established their supremacy.

It is only within the present century that the V. has received any notice in the Western world. One of the first to collect MS. fragments from the *pandits* of Benares was Sir Robert Chambers, whose collection now forms part of the royal library at Berlin. The library of the India Office, London, contains the valuable collection of H. T. Colebrooke. Sir William Jones translated certain portions into English. The first complete translation of the Rig-V. was that of Prof. H. H. Wilson, which was published in 4 vols. after his death (1850-66). The text was edited in Roman characters by Prof. Aufrecht (Berl. 1861). The publication of the Sanskrit text, together with the commentary of Sayana, who lived about 1400 A.D., is the special cause of the sojourn of Prof. Max Müller in this country. His first vol. appeared in 1849, and it is estimated that the whole will be completed in 7 vols. This edition was subsidised by the East India Company, on the intervention of Baron Bunsen. See R. Roth's *Zur Litteratur und Geschichte des Weda* (Stuttg. 1846), A. Weber's *Akademische Vorlesungen über Indische Litteraturgeschichte* (Berl. 1852), Max Müller's *History of Ancient Sanskrit Literature* (Lond. 1859), Dr. J. W. Muir's *Original Sanskrit Texts* (2d ed. 5 vols. 1867-72), and A. Kaegi's *Der Rigveda* (Zür. 1878).

Vedd'er, David, a Scottish poet, born in the parish of Burness, Orkney, in 1790, was in early life a sailor and made several voyages to Greenland, entered the revenue service, and in 1820 was appointed tide-surveyor of customs—an office which he held successively at Montrose, Kirkcaldy, Dundee, and Leith. He died at Edinburgh, February 11, 1854. V. was a votary of the muse from an early age, but his first volume, entitled *The Covenanters' Communion and other Poems*, was not published till 1836. His subsequent works are *Orcadian Sketches* (a medley of prose and verse), a *Life of Sir Walter Scott*, and *Ballads and Lyrics*. In 1841 his collected verse appeared in one volume under the title, *Poems—Legendary, Lyrical, and Descriptive*. V. was also a contributor to George Thomson's *Musical Miscellany*, the *Christian Herald*, the *Book of Scottish Song*, and the famous *Whistle-Binkie*. His verse is marked by spirit and force, and at times has the rare merit of originality. See the Rev. G. Gilfillan's Essay on V.'s Life and Writings prefixed to an edition of his *Poems, Lyrics, and Sketches* (Kirkwall, 1878).

Vedettes' (from *video*, 'I see'), mounted sentries stationed in advance of an army's outposts, in order to watch and signal the approach of the enemy. At night or in thick weather V. should be doubled.

Ve'ga, a star of the first magnitude in constellation Lyra, is situated very near the great meridional circle which passes through Sirius, but on the other side of the Pole Star, from which it is distant about half the distance of Sirius from the same. Consequently at midnight in winter it lies low on the northern horizon as seen from Britain, while in summer it is near the zenith.

Ve'ga Car'pio, Lo'pe Fe'lix de, was born at Madrid, 25th November 1562, and losing his father in infancy was brought up probably by an uncle, the Inquisitor Don Miguel de Carpio. A poet ere he could write, a Latinist from his sixth year, he profited much by two years of study at the Imperial College of Madrid, but with a schoolmate ran away to the Leon fief of his fallen house (1576). A twelvemonth later he was fighting against the Portuguese in the Azores; then, after holding some post about the Bishop of Avila and taking his bachelor's degree at Alcalá, Lope returned to Madrid, and became confidential secretary to Alva, the great duke's grandson, at whose suggestion he wrote his *Arcadia*, a pastoral romance. An unlucky duel, following a prosperous marriage, brought him imprisonment and banishment to Valencia, whose term was scarce over when his young wife died, and Lope, in despair for her loss or a new mistress' scorn, shouldered the musket and shipped on board the Invincible Armada (1588). More fortunate than his only brother, he found himself safe back at Cadiz after a four months' cruise, and presently glorified his country's ruin in the *Drakontea*, the epic consecrated to its hero's shame. During his tenure of two more secretaryships he laid the foundation of his dramatic fame; but marrying again (1597), again to become a widower, saddened moreover by the death of a lawful and a base-born son, he turned to religion, and, taking the tonsure at Toledo (1609), became a Franciscan, a zealous familiar of the Holy Office, a doctor of theology, and chief chaplain of the native priesthood of Madrid. Not that as churchman Lope shunned the world; rather, his cloistered leisure was given to writing the bulk of those unclerkly comedies that made him the idol of high and low, and brought him riches, soon squandered in thriftless charity. Only immediately before the end he fell into a settled melancholy, and hastened that end by fasting and cruel discipline, dying at Madrid, 25th August 1635. Reputed author of 21,000,000 verses, Lope was entitled the 'Monster of Literature' by his less popular compeer, Cervantes; and even the *Globe* itself could not contain a catalogue of all his works —the epics, pastorals, elegies, sonnets, and myriad such-like echoes of the Italian muse. Nor upon these did either his living or posthumous success depend, the *San Isidro* (1598), *Hermosura de Angélica* (1602), *Jerusalen Conquistada* (1609), *Pastores de Belen* (1612), *Corona Tragica* (1627), and *Laurel de Apolo* (1630), being words and mere words—names rather, one should say—tedious and highflown, utterly lacking the old Castilian fire. Out of the thousand couplets of the mock-heroic *Gatomachia* (1634), a few survive as proverbs; and some of his lighter essays —gay songs and roundelays, ballads and *glosas*—outlive their ponderous and learned brethren. It was as playwright Lope won his spurs, a playwright too of the most national type. He entered the lists against the Erudite School, then striving to rear a theatre on classic lines, and wrote for his auditors, the pit that paid. The vulgar, he knew, admire a mirror more than a Raffaelle; and so he deliberately Castilianised every subject, classical, sacred, or mediæval, and owned in

his *Arte nueva de hacer comedias* (1609) that six alone of his 483 *best* plays were fairly regular; which six, no critic ventures to decide. Ticknor divides his dramas into four principal classes, under 'Comedias de Capa y Espada' (genteel), grouping *El Azero de Madrid* (prototype of *Le Médécin malgré lui*), *La Noche de San Juan*, and *El Premio del bien hablar*; under 'Comedias Heróicas' (historical), *Roma abrasada*, *El Principe perfecto*, *El Nuevo Mundo*, *El Castigo sin Venganza*, and *La Estrella de Sevilla*; under 'Comedies founded on Common Life,' *La Donzella Teodor* and *Cautivos de Argel*; and under 'Autos Sacramentales,' the *Nacimiento de Christo*, *Los Trabajos de Jacob*, and *La hermosa Ester*. Dwelling exclusively on the local existing manners of a narrow, artificial age, and sacrificing all interests to the interests of plot, Lope wrote not for the foreigner or futurity. His plays remain an inexhaustible storehouse, whence Dryden professed to have taken more than from all the French and Italian authors put together; but Lord Holland read only 56 of them, Sismondi 36, and hardly a living Spaniard has mastered half that number. Lope's miscellaneous works were published at Madrid (21 vols. 1776), and a selection from them by Don Cayetano Rosell is included in the Collecion Rivadeneyra (Mad. 1856), as well as one (4 vols. 1855–60) from his comedies, the completest edition of which is in 25 vols. (Mad. 1604–47). See, besides the authorities cited under SPANISH LANGUAGE AND LITERATURE, Lord Holland's *Lives of Lope de V. and Guillen de Castro* (2d ed. 2 vols. Lond. 1817), Southey in the *Quarterly Review* (vol. xviii. 1817), and Ernest Lafond's *Études sur la Vie et les Œuvres de Lope de V.* (Par. 1857).

Veg'etable I'vory, See IVORY, VEGETABLE.

Veg'etable Marr'ow. See GOURD.

Veg'etable Physiol'ogy is the section of botany embracing the vital phenomena of plants, and the functions of their various organs. As a scientific study it dates from the time of Stephen Hales (q. v.). All organic life requires the presence of water, it being an abundant constituent of protoplasm, and therefore essential for cell-development; and as the plant grows it is further necessary as a solvent of the reserve materials which from time to time have to be transported in all directions through the structure. In addition, for our ordinary flowering-plants to thrive, water sucked up by the root-hairs flows in a current throughout their system to recoup the loss from leaf-evaporation. The essential elements of plant-food are carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, chlorine, iron, manganese, potassium, and calcium. The root-system absorbs nutrient substances in a variety of compounds, and the leaves absorb a proportion in a gaseous condition. By a process called assimilation this raw food undergoes important transformation, through the influence of light, in those cells of the plant which contain Chlorophyll (q. v.). The actual growth of the plant is the result of this assimilation, a portion of the products serving for present use, and the balance forming a store of reserve material (see SAP, and SECRETIONS, VEGETABLE). The organs of a plant can only perform their functions within a range of temperature from above freezing-point of the sap to a maximum of about 120° F. The most refrangible rays of light are chiefly concerned in influencing growth. Gravitation exercises a powerful influence on growth. The above general statements do not apply to the bulk of cryptogamia, nor to the vital phenomena of parasitic and carnivorous phanerogamia. As to the functions of the various organs, information has been given in the articles ROOT, STEM, LEAVES, FLOWER, STAMEN, PISTIL, FRUIT, and it is only necessary to add here a short statement of the mode of reproduction in the vegetable kingdom. There are two distinct modes of reproduction, and plants usually possess both: they are distinguished as the non-sexual and the sexual. The first named occurs in a variety of modifications, and is variously termed reproduction by *spores*, *conidia*, *gonidia*, *gemmæ*, *bulbils*, *buds*, &c. In the lower plants the most common mode of multiplication is by the Spore (q. v.). Conidia are nearly related to spores, are indeed spores under abnormal surroundings, and gonidia may be regarded as a higher condition of conidia, and are almost peculiar to Lichens (q. v.). In gemmæ the cells are united into regular groups, in which condition they detach themselves from the parent plant; they especially occur in the *Muscineæ*, in Hepatics (q. v.), being developed in special bowl-like conceptacles, and in Mosses (q. v.) in all parts of the plant. Bulbils become spontaneously detached from the parent plant, and falling to the ground continue to grow like seedlings. The mode of reproduction by buds is of the highest practical importance, since by it gardeners propagate from *cuttings*, *runners*, &c., and by the operations known as *Grafting* (q. v.), *budding*, *layering*, &c. In sexual reproduction cells of two different kinds are necessary to produce the new plant by their mutual action one on the other. The process is called *fertilisation* or *impregnation*, and involves a distinction between the fertilising or *male* element, and the fertilised or *female* element. In the flower of an ordinary flowering-plant we find an external calyx and corolla protecting the organs of reproduction, the outer being the Stamen (q. v.) holding the pollen, and the inner the Pistil (q. v.) which embodies the Ovule (q. v.). The period of maturity of the pollen and of the capacity of the ovule for fertilisation generally coincides with that of the expansion of the flower. The pollen grains are carried to the *stigma* by varied and complicated contrivances, wind and insects being the principal active agents. The operation is called *pollination*. When pollination has been accomplished, the pollen-grain, excited by a viscid fluid excreted by the stigma, puts out one or more long tubes. These penetrate through the tissues of the *style* and reach the cavity of the ovary, where they come in contact with the ovules and attach themselves closely to them, fertilising one or both of the *embryonic* or *germinal vesicles* contained in the *embryo-sac* of the ovule resulting in the formation of the *embryo*. If two vesicles are fertilised, one almost invariably perishes while the other undergoes further development. During growth the embryo is almost always nourished by tissue developed in the embryo-sac, and termed *albumen* or *endosperm*. If the whole of the albumen is absorbed by the growth of the embryo, the mature seed is *exalbuminous*; if a portion of it is left, the seed is *albuminous* (see SEED). The processes concerned in fertilisation and formation of the embryo in the gymnosperms differ somewhat from the above, but not sufficiently so to require detail.

Vegeta'rianism, the practice of subsisting solely upon vegetable food, has of late years come prominently before the public in connection with dietetic reform. In a state of savagery, man's instincts lead him quite as strongly towards an animal as to a vegetable dietary. An animal's adaptability to any special kind of food in reality depends on and is indicated by such circumstances and conditions, as (1) the nature of the teeth, (2) the length and complexity of the digestive canal, (3) climate, (4) habit and constitution. Thus, judged by his teeth and digestive system, man is adapted for a mixed diet, and not exclusively for vegetable food. His digestive system stands midway in point of length and complexity between the long and complex alimentary tract of the plant-eating animals and the short and simple digestive tube of the carnivora. The modifications produced, however, in human food by habit, constitution or race, and climate, are numerous and important. Thus the Eskimo by nature lives largely on fat and blubber—such foods being heat-producers. In the northern regions of the earth man must perforce be an animal feeder, because he requires heat, and because no adequate plant-life is developed in such latitudes. The Hindu, on the other hand, exemplifies a case in which a plant-dietary is well adapted to his race, habits, and climate. In temperate climates, a mixed dietary is that which experience proves to be the most suitable food for man. Vegetarianism is, therefore, in such climates a system not for the many, but for the few. Certain persons of a full habit of body benefit from its practice, but in ordinary cases ill-health may follow the disuse of animal food; and it is to be noted besides, that vegetables not merely require greater digestive power than animal food, but that they also contain much less nourishment in proportion to their bulk. Probably the practice of V. has done service in showing that, as a rule, a less quantity of animal food than is generally taken is sufficient to support the body in health.

Vehm'gericht. See FEMGERICHTE.

Ve'ii, a city of ancient Etruria, on the banks of the Cremera, about 12 miles N. of Rome, near the modern *Isola Farnese*. It is said by the Roman historians to have been strongly fortified, rich, and populous at the founding of Rome, and to have possessed territory extending along the right bank of the Tiber, from Soracte to its mouth. A struggle soon commenced between

the two cities, which lasted for three and a half centuries, in fourteen distinct wars, and which was ended by the capture of V., after a ten years' siege, by the dictator Camillus (396 B.C.). The chief incidents in the long struggle were the episode of Porsena (q. v.), and the slaughter of the Fabian clan by the Veientes in 476 B.C.

Veil, the thin gauzy face-covering in common use among ladies in civilised communities. It occupies an important place in the symbolism of marriage ceremonies; hence nuns on entering on their union with the Church are said 'to take the V.' The veiling of the face of women among Mahommedan communities is very strictly enforced, it being regarded as gross pollution to allow any stranger or heretic to see the uncovered face.

Veins, those blood-vessels of animals which return impure blood to the heart and lungs or breathing organs for purification. The *pulmonary* V., however, return *pure* blood from the heart to the lungs; and the *portal* V. carry venous blood to the liver, where it is utilised in the manufacture of bile. The V. are composed of three coats. The internal coat is of delicate tissue, lined with epithelial cells. The middle coat consists of muscular fibres, and the outer coat of areolar tissue, and is thicker than the corresponding coat in an artery. The great majority of the V. are provided with *valves*. These valves are pocket-like folds of the lining membrane of the vessel, and essentially resemble the semilunar valves of the aorta and pulmonary artery of the heart. The free margins of the valves in the V. are turned towards the heart, so that the pockets distend and fill, if the current of blood should pass backwards in the V. Most commonly the valves in V. exist in pairs. The blood in the V. is forced towards the heart chiefly by muscular pressure. The ordinary movements of the body thus assist the flow of blood in the V., and the valves, as already remarked, prevent regurgitation. The valves are most numerous in the V. of the legs. The *venæ cavæ* and portal V., as well as the hepatic, renal, and pulmonary V., are destitute of valves.

The principal *diseases* of the V. are described under Phlebitis, Phlebolithes, Thrombosis, Phlegmasia Dolens, and Varicose Veins.

Veins, in geology, are bands or threads of mineral traversing some other and older rock. The small V. which we see in great abundance running through rocks of almost every age, both igneous and stratified, seem to have been mere cracks produced during the process of cooling or solidification, and in which afterwards quartz, carbonate of lime, pyrites, or some other mineral has become deposited. The large V., from which we derive the greater part of our supplies of tin, copper, and the precious metals, may extend for many miles, and attain a great and often unknown depth. Their average breadth is from two to three feet. These metallic V., called *lodes* by the Cornish miners, frequently coincide with Faults (q. v.), and appear to have been huge rents or fissures produced by earthquakes or other great convulsions. The sides of the V. are in many instances striated and polished by being rubbed against each other during the formation of the fissure. These smooth surfaces are known to the miners as 'slickensides.' Pebbles and fossils which have been now and then found in V. prove these to have communicated with the surface of the land, or the bed of the sea. The Cornish lodes are said to vary greatly in their metallic richness according to the rock which they pass through. 'A vein, for instance, which yields abundance of ore in granite, may be unproductive in clay-slate or Killas, and *vice versâ*.' V. may be straight or tortuous; of uniform thickness, or alternately swollen and contracted; and, lastly, not unfrequently show evidences of having been repeatedly opened up, each time receiving a new deposit of mineral.

Veit, Philipp, a German painter, was born at Berlin, February 13, 1793. His mother, a daughter of Moses Mendelssohn, having procured a divorce from his father, became the wife of Friedrich Schlegel; and the lad was thus brought directly under the influence of Schlegel's philosophy. He studied painting under Friedrich Matthäi at Dresden, went to Rome in 1825, and worked along with Cornelius, Schadow, and Overbeck. In 1830 he was appointed director of the Städel Institute at Frankfurt; but his fanatical attachment to the principles of the Romantic school induced him to resign his office in 1843, because the institute had bought Karl Friedrich Lessing's 'Huss before the Council of Constance.' At first he settled in the suburb of Sachsenhausen, on the other side of the river from Frankfurt; but he was afterwards called to be director of the picture-gallery at Mainz, where he died, 18th December 1877. Among his paintings—which were mainly Biblical or ecclesiastical—it is sufficient to mention the 'Scenes from Dante's Paradiso' in the Villa Massimi at Rome (*fresco*), the 'Introduction of Christianity and the Arts into Germany' in the Städel Institute (*fresco*), the portraits of Karl the Great, Otto IV., and Friedrich II. for the imperial chamber at Frankfurt, an 'Ascension of the Virgin' for the Frankfurt Cathedral, and the 'Two Marys at the Grave' for the King of Prussia.

Veitch, Rev. William, LL.D., an illustrious Scottish scholar, belongs to an old Border clan, and was born at Spittal, in Roxburghshire, towards the close of last century. He was grounded in learning, under Dr. Lorraine, at the parish school of Jedburgh, whence he passed to the University of Edinburgh, where he was contemporary with Edward Irving and Thomas Carlyle. The professors who exercised the greatest influence on V. were Christison (Latin), Dunbar (Greek), and Brown (Moral Philosophy), for all of whom he still cherishes an affectionate remembrance. V. studied for the Church of Scotland; but, though one of the most learned and loyal of her sons, he never undertook the charge of a parish. On the completion of his university curriculum he settled in Edinburgh, where his long life has since been almost uninterruptedly devoted to Greek and Latin philology. The fruit of an immense and honourable industry is seen in his *Greek Verbs, Irregular and Defective* (1848), a work unique in its character and merits, and one which in all probability no other man in the United Kingdom could have produced. When it first appeared there was scarcely sufficient learning in this country to appreciate its rare quality, but it soon won recognition from the great linguists of Germany, with several of whom, *e.g.*, W. Dindorf, G. Curtius, K. W. Krüger, W. Pökel, &c., V. has long held friendly intercourse; and some years ago the Clarendon Press Delegates paid the venerable scholar the highest compliment in their power by placing his volume in their series of publications. In this form it has become widely known in England, and is now (1879) in its third edition. V. also gave the Delegates valuable help in their new edition of Liddell and Scott's *Greek Lexicon*. In 1868 his *alma mater* conferred on him the degree of LL.D. V.'s familiarity with the text of a Greek author could not be surpassed by an Alexandrian grammarian, and has enabled him to destroy with that fatal 'weapon of precision,'—a quotation, many a time-honoured dogma in the creed of lexicographers. Although relentless where the honour of scholarship is concerned, he is a man of genial and vivacious humour, and full of Border lore and anecdote, subjects on which he lingers 'with fond recollection.'—**John V., M.A., LL.D.**, a Scotch professor and author, was born at Peebles, 24th October 1829, studied at the University of Edinburgh, and in 1850 published a translation of Descartes' *Discours de la Méthode*, with a preliminary essay on the Cartesian philosophy. It was followed in 1853 by a translation of the *Meditations*, &c. From 1855 to 1860 he acted as assistant to Sir William Hamilton and his successor in the chair of Logic and Metaphysics, Professor Fraser, when he was himself appointed to the chair of Logic, Metaphysics, and Rhetoric in the University of St. Andrews. Along with the late Professor Mansel of Oxford, he edited Sir William Hamilton's *Lectures on Metaphysics and Logic* (1859-60). He was transferred in 1864 to the chair of Logic and Rhetoric in Glasgow University, and in 1869 published a Memoir of Sir William Hamilton. In 1872 he received from his *alma mater* the degree of LL.D. Since then V. has apparently abandoned philosophy for poetry and the lighter sorts of literature, his latest works being *The Tweed and Other Poems* (1875), and *The History and Poetry of the Scottish Border* (1877).

Velas'quez, Don Die'go Rodrig'uez de Silva y, the greatest of Spanish painters, was born of a Portuguese family at Seville, 6th June 1599. From the studio of Francisco Herrera, an artist of some note, he passed to that of Pacheco, whose daughter, Juana, he married in 1620. His early art, humble in aim and somewhat vulgar in type, is seen at its best in the 'Water-Carrier' (Aquador) at Madrid, a work of characteristic vigour and keenness. To this early experience has been ascribed a certain want of elevation in his later work, an absence of the higher eclectic spirit manifested by tolerance of the painful or

ugly. In 1622 V. went to Madrid, where in the year following his portrait of Olivarez procured him the patronage of Philip IV., a wonderful portrait of whom at once established the fame of the painter. As court painter he produced many portraits of the royal family and of illustrious visitors, the latter including one of Charles I. of England, which has been lost. V. formed a cordial friendship with Rubens during the diplomatic visit of the Fleming to Madrid in 1628. In 1629–31 he made a tour in Italy, visiting Rome, Naples, Florence, Venice, &c., and being received everywhere with the highest distinction. His style, already fully developed, bears little trace of Italian influence, but his admiration was sympathetically touched by the glory of Venetian art, and he expressly records his preference for Titian over Raphael and Michael Angelo. On his return to Madrid he made rapid progress in the royal favour; he was made royal Ayuda de Camera or chamberlain (1643); his studio was removed to the palace, and there in friendly converse with the painter the king spent much of his leisure. This relationship was undisturbed by V.'s grateful conduct to the disgraced favourite, Olivarez, and in 1648 he was sent by the king to Italy, commissioned to buy works of art. At Rome he painted the portrait of Innocent X., which is now the gem of the Doria gallery. He was subsequently appointed Aposentador Mayor, or royal seneschal, and in 1656 received the Cross of Santiago, an honour till then reserved for the highest nobility. But V. did not thrive under his load of honours; his health gave way in the service of the court; and he died at Madrid, 7th August 1660. His wife, to whom he was passionately attached, was laid beside him in the church of San Juan two weeks later. Although there are specimens of V. in the galleries of London, Paris, Vienna, Munich, &c., it is only at Madrid that the range and resource of his art can be duly estimated. His portraits are not mere, 'sallow, mustachioed Spaniards in black cloaks,' but veritable human counterfeits, strong, vivid types of individuality, instinct with the subtlest shades of expression. The 'Adoration of the Magi,' his earliest-known picture, bears date 1619, and among his better-known works are the 'Boracchos,' 'Forge of Vulcan,' 'Joseph's Coat,' 'Surrender of Breda,' a 'Crucifixion,' 'Dwarfs,' 'Coronation of the Virgin,' 'The Meniñas' or 'la Familia' (royal family), the 'Hilanderas' or 'Spinners,' and, his last, 'St. Anthony the Abbot visiting the first Hermit St. Paul in the Desert' (1659), of which Wilkie says it has 'the very same sun we see, and the air we breathe, the very soul and spirit of nature.' His historical pictures are grandly representative, and combine imaginative power with technical dexterity. Only in the treatment of religious subjects does he fail of the highest success, and only fails in defect of that sacrosanct purity, that spiritual majesty, which was the rare gift of the older Italians. Courts could not make a courtier of V., whose main characteristics are dignified repose and uncompromising honesty. The brown tone, dark shadows, and hard outlines of his earlier style were gradually replaced by a chord of silvery-grey, by aerial clearness and transparency, and a finer gradation of tints. His versatility is seen in his triumphant treatment of animals, landscape, and domestic life. As a colorist V. belongs to the first rank; his execution, strong, rapid, and rugged, has exerted a powerful influence on painters so unlike as Wilkie and Phillip, as well as on the modern Spanish school represented by Madrazo and Fortuny. See Stirling, *V. and his Works* (Lond. 1856); Fr. Pacheco, *Arte de la Pintura* (Mad. 1866); Eastlake, *History of Oil-Painting;* Madrazo, *Discurso Inaugural* to the Academy of San Fernando (Mad. 1870), and an article in the *Quarterly* (vol. 133, 1872).

Velell'a, or Sallee' Man, a species of *Cœlenterate* animals in some degree related to the jellyfishes, but distinguished by the diagonal crest or sail borne on the upper surface of the organism, and which is used as a means of propulsion. The bulk of the V. (of which *V. vulgaris* is the common species) consists of the rhomboidal *pneumatophore*, or float bearing the diagonal crest, placed vertically. A single polypite depends from the flat structure, with reproductive bodies and tentacles. The average length of the V. is about 2 inches long by 1½ inches in height. The organism is of a beautiful delicate blue tint.

Velez' Mal'aga, a town in the province of Malaga, Spain, on the left bank of the Velez, 16 miles E. of the town of Malaga, and 2 miles N. of the Mediterranean coast. It is an old, decayed-looking place, but has a lucrative trade. Two fine churches and the ruins of a high Moorish tower are its chief buildings. The fine climate, combined with constant water-supply, favours the growth of sugar-cane, rice, cotton, palms, oranges, maize, sweet potatoes, &c.; much wine is also produced. Numerous ancient towers along the sea-coast (some probably Carthaginian), are now used as watch-towers. Pop. 16,000.

Ve'liki-Lu'ki, an old town of Russia, government of Pskov, on the Lovat, 124 miles N.W. of Smolensk, with 9 churches and 2 monasteries, and manufactures of Russia and other kinds of leather. Pop. (1871) 5714.—**V.-Ustiug'**, a town of Russia, government of Vologda, at the junction of the Jug and the Suchona, 240 miles N.E. of Vologda, and on the great road from Archangel to Siberia. One of the principal seats of industry in N. Russia, it has active manufactures of cloth, linen, leather, soap, wax-candles, enamelled gold and silver wares, and a large trade in furs. Pop. (1871) 7792.

Veli'no. See TERNI.

Velle'ia, or **Vele'ia**, a town of ancient Liguria, the remains of which are 24 miles S.E. of Piacenza. It is believed to have been buried by a landslip in the reign of the Emperor Probus, though we have no contemporary record of such an occurrence. In 1747, the discovery of a bronze tablet led to extensive excavations being commenced in 1760, which were continued until 1775, and resulted in the discovery of an amphitheatre, temple, and forum, besides a great quantity of antiquities now in the museum at Parma.

Vellei'us Pater'culus. See PATERCULUS.

Velle'tri (the Volscian *Velitræ*), a town of Central Italy, province of Rome, picturesquely situated on a spur of the Alban Hills, near the Pontine Marshes, 26 miles S.E. of Rome by rail. It is the seat of the Bishop of Ostia, and has a cathedral (San Clemente), a classical school, a technical school, and several fine palaces. On the 19th March 1849 V. was the scene of a defeat of the Neapolitan troops by the Roman Republicans under Garibaldi. Pop. (1874) 13,584.

Vellore', the most populous town of the district of N. Arcot, Madras Presidency, British India, near the left bank of the Palar river, 80 miles W. of Madras by rail. Pop. (1871) 38,022. The old fort, which was formerly very strongly garrisoned, now contains only a single regiment of native infantry. Inside there is a pagoda, with beautiful stone carvings. A central jail has lately been built for 1000 long-term prisoners, where excellent carpets, rugs, &c., are manufactured. V. was the scene of a mutiny in 1806, when the native sepoys rose and murdered 113 European officers and soldiers. The outbreak was promptly suppressed. It was supposed to have been instigated by the sons of Tippoo Sultan, who had been confined in the fort as state prisoners since 1799. They were forthwith removed to the neighbourhood of Calcutta, where the last survivor died in 1875. See Kaye's *History of the Sepoy Mutiny* (vol. i.).

Vello'zia, a genus of plants belonging to the small monocotyledonous natural order *Hæmodoraceæ*, or the blood-root family. Tree-lilies is the name applied to the commoner species. Their height varies from 2 to 10 feet; the branches terminating in tufts of stiff aloe-like leaves and large solitary blue, white, or violet flowers. As V. grows it continues to bear the withered remains of the leaves, and the surface of the trunk as it ages is enveloped in a mass of adventitious adpressed rootlets. In the dry mountain regions of Brazil V. is a marked feature of the scenery.

Vell'um. See PARCHMENT.

Velo'city, in kinematics, is the rate of change of position of a point per unit of time. Change of position is essentially a Vector (q. v.), and when this change of position is considered with reference to time the vector quality still remains. Hence we see that V. is a vector, and as such subject to all the laws which regulate such quantities. A body describing spaces proportional to the times is said to move with uniform V., which is then found numerically by dividing the space described in any time by that time. Unit velocity is defined as the V. with which a moving point describes unit space in unit time; hence since $v=\frac{s}{t}$ we see that a velocity is of *one* dimension in length and *minus one* dimension in time, or involves the length unit directly and the time unit inversely. If the V. changes from

point to point, then the V. is said to be variable. In such a case if we divide the space described by the time taken to describe it we get what is called the *average velocity* during that time; and if the time of description be taken shorter and shorter this average V. will more nearly approach in value the real V. during the interval. In this way we may approximate more and more to the value of the V. at any instant, but only if the V. suffers no abrupt change during the short interval of time chosen. The possibility of *measuring* a variable V., however, does not affect the conception of such a V., which must have a finite value at any given time. Remembering that a V. is defined as rate of change of position of a moving point, or in other words the rate at which the path of a moving point grows, we may follow Newton and represent the V. by the fluxion $\dot{s}$ where s is the position of the moving point measured from an arbitrary origin along the path; $\dot{s}$ is a finite quantity, and when we say that the V. of a moving body at the point s is $\dot{s}$, we mean that if the body were then left to itself it would proceed in the direction of the tangent to the curve at s with a velocity represented by $\dot{s}$. The rate at which the velocity changes is called the acceleration, and may be represented by the symbol $\ddot{s}$. See KINEMATICS, MOTION, LAWS OF, &c.

Vel'vet (Old Eng. *velouette*, from Old Fr. *velous*, Lat. *villosus*, 'hairy'), is a silken textile, woven with a looped surface which is cut, and forming a thick, close-set pile. The art of weaving V. probably originated in China. In mediæval times it was much valued for ecclesiastical vestments and costly church draperies. Patterns were woven in V. by introducing pile of different colours, or the same colour in different lengths, and in this style the Italians, Spaniards, and Flemish excelled.

Vendace' (*Coregonus Willoughbii*), a peculiar species of *Teleostean* fishes, belonging to the family *Salmonidæ* (q. v.), and noted for its peculiarly local distribution. It occurs at Lochmaben, in a few English lakes, and in several Swedish waters. The average length of the V. is about 6 or 7 inches. Its body is deep, and of compressed shape, and the under jaw projects beyond the upper. The tail is forked, and the body tapers markedly. The back is brown, and there is a heart-shaped patch of red hue between the eyes. The spawning season is in November and December. The V. is highly esteemed as a food-fish, despite its small size. It is fished at the beginning of August, and is caught in sweep-nets. See COREGONUS.

Vendée, a department of France, formed from a part of Poitou, bounded N. by the departments of Loire Inférieure and Maine et Loire, E. by Deux Sevres, S. by Charente Inférieure, and W. by the Atlantic Ocean, along the coast of which are several islands belonging to it, the largest Dieu and Noirmoutiers. Area, 2588 sq. miles; pop. (1876) 411,781. V. divides itself naturally into three divisions; the *Bocage*, in the N., a part of the former district known as V., still largely covered with wood crossed by several small streams, and yielding wine, fruit, and vegetables; the *Plaine*, comprising the whole district between the Bocage and the S. frontier, a fertile tract, but without adequate water-supply; and the *Marais*, a swampy tract along the coast, part of which has been made fit for cultivation by a system of canals and dikes. The collieries of V. yielded (1875) 316,748 metrical quintals: and in 1876 its agricultural produce was wheat (6,050,000 bushels), barley (695,200 bushels), wine (20,809,360 gallons), besides oats, buckwheat, flax, turnips, hemp, and rapeseed. The capital is Roche-sur-Yon (q. v.). The Vendean insurrection against the French Revolution is noticed under CATHELINEAU, CHOUANS, and LAROCHE-JAQUELEIN. See also Daniau's *Histoire de la V.* (vols. i.-ii., Angers, 1878).

Vendémiaire ('wine-month'), in the calendar of the First French Republic, the period from September 23 to October 21.

Vendett'a (Ital. 'vengeance,' from Lat. *vindicare*), the Corsican system of private feud by which the kinsfolk of a murdered man were bound to avenge his death; either by slaying the actual murderer, or, in the case of his escape, his relatives. Such feuds accordingly might extend to entire families and clans, to villages and districts, and, handed down from one generation to the other, might outlive their motive by fifty years. Even to-day, in spite of the energetic measures of the Italian government for its repression, the evil has hardly yet been extirpated in Corsica; and in Sicily (q. v.), nourished by the *omertà* and communal *mafias*, it flourishes with increased ferocity. In the V. one recognises a survival of that primitive and world-wide principle that the individual must defend himself and his from wrong-doing or avenge a committed wrong, which presents itself in the Avenger of Blood (q. v.) of Mosaic time, at Athens in the defence of the slayer of Eratosthenes (403 B. C.), at Rome in the *Lex Julia de Adulteris* (17 B.C.), in the old Teutonic *fæde* or Feud (q. v.), and at a later date among the Albanians, Beduins, Circassians, Australian aborigines, and other uncivilised races. That principle lies at the root of all criminal jurisprudence, since, with the gradual widening of the social circle, the individual's wrong concerns the *gens*, the tribe, the nation; and thus by degrees his right to defend himself against his wrongdoers become the state's to defend itself against the misdoings of its own members by legal punishment, or against the misdoings of other states by formal war. See WEREGILD and Lecture VI. of Freeman's *Comparative Politics* (Lond. 1873).

Vendôme', a town of France, department of Loir-et-Cher, on the Loire, 34½ miles N.N.E. of Tours by rail, contains a ruined château, five churches, of which La Trinité dates from the 15th c., a college founded by César, Duc de V. (1594-65), a lyceum, public library, theatre, &c. Glove and paper making form with tanning the principal industries. Pop. (1872) 9259. Capital of a former duchy, V. was the scene of conflicts in the Franco-German war (15th December 1870 to 6th January 1871).

Vendôme', Louis-Joseph, Duc de, grandson of a natural son of Henri IV., was born in Paris, 1st July 1654, and till his father's death in 1669 bore the title of Duc de Penthièvre. He entered on a career of arms under Turenne's guidance (1672), served with distinction in Elsass, Piedmont, and Catalonia, forcing Barcelona to surrender (1696), and on the outbreak of the Spanish War of Succession (1700) received the command of the French army in Italy. In 1703 attempting to force a passage through the Tyrol and effect a junction with the Elector of Bavaria, he was brought to a stand at Trent by the valiant resistance of the mountaineers; but in the autumn of the same year he disarmed the troops of the Duke of Savoy, who had broken with France, took several fortresses of Piedmont, and opened the long investment of Turin. In 1706 he had just profited by Prince Eugen's absence to drive the Imperialists across the Adige, when he was recalled to the Netherlands, and there, after taking Ghent and Bruges, was crushingly defeated at Oudenarde (q. v.) in 1708, and had to yield Lille to the Allies. This reverse and the machinations of Mme. de Maintenon brought him two years' disgrace; but at length the desperate state of the French cause in Spain forced Louis to send him once more to the Peninsula, where, having brought Philip V. back to Madrid, he made Stanhope and 5000 English prisoners at Brihuega, and next day virtually ended the war by his victory over Starhemberg at Villa-Viciosa, 9th December 1710. He did not long enjoy the honours now showered upon him, dying at Vinaroz in Valencia, 15th June 1712. A singular medley of strength and weakness, V. was an indolent and thoughtless gourmand, but could rouse himself in a sudden emergency, then acting with keen and cold-blooded energy. See St. Simon's *Mémoires*; Voltaire's *Siècle de Louis XIV.*; Villeneuve, *Éloge du Duc de V.* (Agen 1783); and *Le Duc de V. en Espagne* (Par. 1824).

Veneer' (Ger. *furnieren*, 'to veneer,' 'to inlay'), a thin slice of fine wood, ivory, or tortoiseshell, fastened with glue and strong pressure to another material for ornamentation. The process, which is termed *veneering*, was known to the ancients, and is still extensively practised; furniture, &c., constructed of pine or other inferior wood, being commonly covered with a layer of walnut, rosewood, mahogany, satin-wood, amboyna-wood, thuya, or other valuable and beautiful wood. Veneers are *cut* or *sawn* from the solid block by machinery. Marquetry (q. v.) is an effective application of veneers.

Vene'real Disease'. See SYPHILIS.

Vener'idæ, a family of shells belonging to the *Molluscan* class *Lamellibranchiata* (q. v.), and to the section having large respiratory *siphons* or breathing-tubes. The shell is orbicular or oblong, and has a toothed hinge and an external ligament. The foot is tongue-shaped, and the mantle has a large anterior opening. The siphons are unequal, and are usually more or less completely united. Some of the V. are among the most highly-organised of their class. To this family belong the exist-

ing Venus-shells, and the well-known genus *Cytherea*. Both are first found as fossils in the Oolitic rocks.

Venesec'tion. See BLOOD-LETTING.

Vene'tian Chalk', a synonym for French chalk, which is simply steatite in mass or powdered.—*V. Lake*, a pigment prepared by mixing a concentrated solution of Brazil wood with alumina and glue.—*V. Red*, a brilliant red ochre obtained from Italy, and extensively employed as a pigment.

Venezue'la, a S. American Republic, composed of twenty-one states, and having an area estimated at 403,275 sq. miles. It is bounded N. by the Caribbean Sea, E. by the Atlantic and British Guiana, S. by Brazil, and W. by the United States of Colombia, but the two last boundaries are not absolutely determined. The country is traversed by two mountain chains, offshoots of the Andes, between which are the great low-lying plains called *Llanos* (q. v.). The northern chain runs N.E. past the southern end of Lake Maracaybo (q. v.) to the sea at Puerto Cabello, and then runs eastward along the coast as far as the Gulf of Paria. Its highest points are, the Sierra Nevada of Merida, 15,342 feet; Mount Picacho, 14,168 feet; and the Silla de Caracas, 8632 feet. The other chain crosses the country to the S. of the River Orinoco (q. v.), and consists of a number of parallel ranges bearing the general name of Mountains of Parimé. They attain a maximum altitude of 10,000 feet, but their average height does not exceed 4000 feet. This part of the country is still very imperfectly known, but is broadly divided into three physical regions, viz.—1. *Tierras calidas* ('hot lands'), reaching up to 4000 feet above the sea-level. 2. *Tierras templadas* ('temperate lands'), between 4000 and 7000 feet. 3. *Tierras frias* ('cold lands'), above the last limit. The first region possesses a luxuriant tropical vegetation, including magnificent forests abounding in valuable timber, medicinal plants, and dyewoods; the second is well suited to the growth of cereals and beans; while the third is comparatively bleak and well-nigh uninhabited. The Orinoco and its tributaries constitute the principal river-system of V., but there are also some considerable streams flowing into Lake Maracaybo and the Caribbean Sea. The indigenous fauna include the puma, ounce, jaguar, deer, monkeys, alligators, and snakes, and birds of many kinds. Cattle, horses, and mules are now reared in great numbers on the extensive plains. The staple crops are coffee, cacao, cotton, tobacco, and indigo, in addition to which the exports include hides, skins, horns, dyewoods, gold, copper, and salt. Gold is obtained at Caratal, Nouveau Monde, and Callao (in the last two places since January 1879), and copper at Aroa, which is connected by a railway 70 miles long (opened February 7, 1877) with the port of Tucácas on the N. coast. Commerce is much hindered by the lack of roads and of better means of transport than mules. The *Estadistica Mercantil* of November 1877 gives the gross imports for the financial year 1875-76 at £2,777,572 (28 per cent. to England, 17 per cent. to the United States, 16¼ per cent. to France, 14⅜ to Germany, and 8 per cent. to the English colonies), the duties on which amounted to £964,112; and the exports at £3,098,582 (coffee, £2,194,136, of which £9010 to England; cacao £288,790, of which £2692 to England; cotton £105,390, hides, goatskins, and deerskins £126,239). The number of ships entering the ports of V. in 1874 was 2200 (at La Guayra 175 of 148,360 tons, at Puerto Cabello 256 of 126,260 tons). In 1878 the imports from England had a value of £473,584, the exports to England of £97,079; and in 1876 the public debt, interior and exterior, amounted to £12,817,825. The capital is Caracas (q. v.), and the other chief towns are Cumana (q. v.), La Guayra (q. v.), Puerto Cabello (q. v.), and Angostura (q. v.). Several of the towns of V. have suffered severely from earthquakes at various times. The pop. of V. in 1873 was 1,784,194, of whom one-third were whites, one-half Zamboes (a mixed Indian and Negro race), and only one-thirtieth pure Indians. The last are the most industrious portion of the population. V. was discovered by Columbus in 1498, and in 1499 Vespucci and Ojeda seeing in Lake Maracaybo the Indian village of Cora, which was built upon piles, named it V., or Little Venice, an appellation subsequently extended to the whole country. In 1813 V. revolted from Spain, and in 1819 was recognised as forming with New Granada and Ecuador the independent Republic of Colombia, but in 1831 V. separated from the other states, and became a republic in 1863. Since then it has been the scene of perpetually recurring civil wars. At present (April 1879) a 'revolution' is in progress. See Sach's *Aus den Llanos* (Leip. 1878), Tejera's *V. Pintoresca, &c.* (2 vols. Par. 1878), and Spence's *Land of Bolivar* (Lond. 1877).

Ve'nial Sins. The distinction made in Roman Catholic theology between mortal sins and V. S. was first made in connection with Church discipline. St. Augustine in his book of *Faith and Works* distinguishes sins into two kinds: greater, or those which obliged men to do public penance, and which he called mortal; and lesser, such as sins of the tongue and thoughts, and the immoderate use of lawful things, which he called *venial*, not because they were not mortal in their own nature, but because in comparison with the others they were of an inferior nature, and not so easily proved on men; and because men were cleared from them without the humiliation of a public penance, by private repentance, and daily prayer and reformation. The same distinction is made in the writings of many of the early Fathers. The sins for which public penance had to be undergone were all enormous sins, such as idolatry, apostasy, divination, murder, adultery, theft, and sacrilege. But this is not the distinction which is made in later theology in connection with the doctrines of purgatory and auricular confession, and especially in the writings of the casuists. There is so much diversity of opinion among the writers themselves that no precise definition of V. S. can here be given, farther than that they are those minor sins to which even the best are liable, and from which even those who escape the punishment of hell have to be purified in Purgatory (q. v.) before they can enter to heaven.

Ve'ni, Crea'tor Spir'itus, is the first line of a fine old Latin hymn occurring in the Roman Breviary in the offices of the Feast of Pentecost. It is popularly ascribed to Karl the Great, but is certainly older than his time, and is probably the composition of Gregory the Great. It has always been used in the church on occasions of extraordinary solemnity, as at the creation of popes, &c. The estimation in which it has been held is shown by the circumstance that it is the only hymn retained in the liturgy of the Anglican Church, in which it occurs in the offices for the ordering of priests and the consecrating of bishops. Another Pentecostal hymn, the *Veni, Sancte Spiritus*, is ascribed to Robert II. of France.

Venice (Ital. *Venezia*, perhaps from Celt. *gwen*, 'a plain'), the pile-built city of the Adriatic, stands at the N.W. angle of the Gulf, on three islands and 114 islets, which, parted by 157 canals, are linked together by 380 bridges. Since 1845 a railway viaduct, 2⅓ miles long, connects it with the Italian mainland, and so with Padua, 23½ miles to the W.; seaward, long insular sandhills, strengthened by mighty walls of white hewn marble and pierced by four openings, shelter the tidal basin of the Lagunes. To the tides which, here rising from 2 to 6 feet, send their pulsations through every vein of this peculiar city, it owes its healthy saline atmosphere; but for long centuries the Brenta, Piave, and other impetuous affluents of the Adriatic, from whose alluvium the islands formed themselves, have striven to turn the Lagunes into a brackish swamp, to raise their bed, and so, by obstructing the natural canals and sea approaches, strip V. of her maritime dominion. And in spite of vast sums expended on the diversion of river channels, on ceaseless dredging, and the construction of dikes and breakwaters, the Porto del Lido (once the main gateway to the outer sea) has gradually become so silted up, that vessels of heavy tonnage must now go round by a southern passage, the Porto del Malamocco. Two schemes are now (1879) before the Government, one to join V. to the mainland by filling up the shallow intervening Lagune (with an area of 124,000 acres); the second and more feasible, finally to remove the Brenta's mouth at a cost of £165,000, and then re-open the Porto del Lido at a cost of £360,000 more. Another pressing want is the provision of better drinking-water than is at present furnished by the 6782 rain-water cisterns dug since 1303; by seventeen artesian wells (1847-52), which, only bored to a depth of 450 feet, are either ferruginous or so gaseous as to flame at the touch of a lighted match, and by the extra supplies brought daily in tanks from the impure Seriola Canal on the nearest mainland. Not till the solving of both these problems can V. be confident of keeping her present, still less of regaining her past, prosperity.

To come to the city itself, the V. of vaporous sea-mists and hue of mother-of-pearl, with waves for horizon, or the far Euganean

Hills, the V. of marble churches and palaces, all glorified with the genius of Pisano, Sansovino, Scamozzi, Palladio, and Canova, of Giorgione, Titian, Tintoretto, and Veronese. About 7 miles in circumference, V. is cleft into two unequal halves by the Canale Grande, which, nearly two miles long by from 36 to 66 yards wide, winds in the form of an inverted S, is spanned by the marble Rialto (1588-91) and two iron bridges (1854-58), and is to V. as the Corso to Rome, the Boulevards to Paris. Canals, indeed, are here the thoroughfares, with sable Gondolas (q. v.) for carriages; sometimes a strip of pavement (*calle*) fringes their margin, oftener the houses rise sheer from the water's edge. By means, however, of 1914 such labyrinthine *calli*, a slender land communication is preserved with the 41 squares, of which the Piazza S. Marco alone deserves the name. Flagged with marble, this is on three sides bounded by the arcaded palaces of the Procurators (15th c.–1810), E. by the metropolitan Basilica of S. Marco (976–1071), a five-domed Romanesque-Byzantine structure, decked with 500 marble columns and 45,790 square feet of mosaics (10th–16th c.). Its form is that of a Greek cross. Alexandrian mosques suggested the general features, marbles from the harem-floors of Eastern emperors panel its sanctuary, and over its principal portal stand the four horses of gilded bronze, which from surmounting the arches of Nero and Trajan at Rome passed to Constantinople in the 4th c., and thence to V. (1204), whither having been carried to Paris by Napoleon (1797), they were restored (1815). From the Piazza the isolated Campanile (911–1591), 322 feet high, and mounted by a spiral upward-sloping plane, uprears for colossal vane a golden angel; the Masts at its foot no longer flaunt their Cyprian, Cretan, and Morean banners, but, opposite, the Torre dell' Orologio (1492, restored 1859) still tells the hours on its quaint automatic dial. During 1800–78, 88 churches and over 200 palaces were demolished, but 99 churches still remain, besides a Protestant, a Greek, and an Armenian church, and 7 synagogues. Of these survivors the following are most noteworthy:—the cruciform Frari (1250–80), with the tombs of Titian, two doges, and Canova, and in whose neighbouring monastery the Public Records (q. v.) are stored; the little 6th c. S. Giacomo; the domed S. Giovanni e Paolo (1240–1430), the doges' sepulchre, but by fire despoiled (1867) of its Cappella del Rosario and Titian's 'Peter Martyr;' S. Maria dei Miracoli (1480; restored 1879); Il Redentore (1577), Palladio's masterwork; the 15th c. S. Rocco, whose adjoining Scuola (1517–50) contains fifty-six paintings by Tintoretto; S. Salvatore (1534–1663; restored 1877), where Caterina Cornaro, Queen of Cyprus lies interred; S. Sebastiano (1506–18), the burial place of Veronese, and S. Zaccaria (1457–1515), of Alessandro Vittoria. Supreme among secular buildings, the Ducal Palace stands S. of the cathedral, fronting the Lagune. Five times destroyed by fire since its foundation in 809, each time to arise with renewed magnificence, it represents the labour of 600 years, its massive colonnades and Gothic loggias dating from the 13th, its eastern façade and inner court from the 16th c., while since 1853 the whole square fabric, 'so beautiful in the regularity of its pointed windows, so singular in its mosaic diaper of pink and white,' has been restored. The Scala dei Giganti, where the doges were crowned, and the Scala d'Oro, once trodden by none save nobles of the 'Golden Book,' lead to vast corridors and council-rooms, which, walled and roofed with priceless masterpieces of Venetian art, are at present occupied by a library of 10,000 MSS. and 130,000 volumes, a coin collection, and archæological museum. To-day the Lion's Mouth gapes idly for denunciations; prisoners no longer traverse the Bridge of Sighs; nay, the Piombi, or lead-roofed dungeons of the uppermost story, are shorn of even their traditionary dread. Across the Piazetta, beyond the two granite columns brought hither from Syria (1120), and marking the place of execution, the Library (now part of the Royal Palace) and Mint stand, triumphs of Venetian architecture (1536), also so splendidly exemplified in sixty-three palaces lining the Canale Grande. Many of these now serve as hotels or public offices, and Palladio's Scuola della Carità (1552) is tenanted by the Academy, the gem of whose gallery of 700 paintings is Titian's 'Assumption.' Of the six theatres, La Fenice (1836) accommodates 3000 spectators; other buildings are the Seminario Patriarcale, the Scuola di S. Marco (1485; a hospital since 1815), an immense female lunatic asylum (1875), two gymnasia, &c. The famous Arsenal, whose archway is guarded by four marble lions, brought from the Piræus (1687), and scored with Runic Inscriptions (q. v.), was the first of its name, being founded in 1104. It extends over 89 acres, and in the 16th c. contained 40,000 sailors and 16,000 shipwrights, who at the shortest notice could turn out a fleet of eighty-five galleys. In 1875 its 2000 workmen built only forty-three vessels of 1310 tons, but signs of renewed activity are the construction (1876–77) of a large dry-dock, two graving-docks, and Free Warehouses, and the recent opening of four lines of navigation, of which the Peninsular and Oriental conveyed 4881 passengers to Alexandria in 1876. In 1877 there entered the port 2885 vessels of 570,014 tons, and cleared 2914 of 580,580 tons, while the imports (oils, colonials, wine, and spirits, silk, cotton, and coal) amounted to £4,803,009; the exports (grain, hemp, timber, glass beads, enamel, &c.) to £1,779,399. The industries of V., like her Arsenal, pride themselves chiefly on past achievements—the Glass (q. v.), mosaics, lace, tapestry, Aldine Editions (q. v.), and exquisite bindings of the 16th and earlier centuries. But some, that survived uninterruptedly, seem to have taken a fresh development; others, intermitted awhile, have lately been renewed. The glassworks, for instance, whence Benedict Biscop procured the windows for his Abbey of Wearmouth (674), could, thanks to Salviati's fostering care, export goods to the value of £2,449,611 during 1862–71, and 1874 saw the revival of tapestry and lace working, the former an art (older than that of Lyon) which once employed 14,000 hands. Wood-carving, too, is again a thriving handicraft; a recent discovery for casting in bronze without modelling in wax or after polishing promises a new era of perfection in bronzes; and lastly, as the abode of above 100 eminent artists mostly engaged upon English commissions, V. bids fair to retrieve the lost laurels of the Venetian School. The pop. from 190,000 had sunk in 1789 to 139,095, in 1857 to 118,172, but upon 31st December 1877 numbered 130,816.

In the days of the Wandering of Nations, when Attila destroyed Aquileia, Padua, and the adjacent towns (452), many of their inhabitants fled to the Lagunes, and 'fixed like waterfowl their nests upon the waves.' The only spot in Western Europe that never acknowledged a Teutonic master, V., from a mere aggregate of tribune-governed islands, became a republic under a single Doge (q. v.) in 697. The barrenness of these islands, whose sole commodity was salt, made commerce a necessity; and seated between the Lombard and Byzantine realms, each needing what the other only could purvey, V. through commerce soon waxed so great as to capture Ravenna (737), gradually to relax her dependence on Constantinople while gaining sovereignty over the Istrian and Dalmatian seaboards, and to repulse the fleet of Pippin (809) from the Rialto, the seat of government thenceforth. Hither were brought the relics of St. Mark, filched from the infidels of Alexandria (829), and here, in front of that saint's basilica, Barbarossa abased himself before Pope Alexander III., who rewarded V. for services then rendered to the Church with the ring of espousal to the Adriatic (see BUCENTAUR). This great event took place in 1177, the age of the Crusades (q. v.), and five years after that founding of a Great Council of 480 members which marks the close of V.'s earlier history, the troublous times when out of fifty doges five abdicated, nine were deposed, five massacred, and five sent blinded into banishment. The Crusades gave V. an enormous impulse, shown in her undertaking (1201) to transport to Palestine 30,000 men and 14,000 horses for 85,000 marks, in her capture of Constantinople (1204) under blind old Dandolo (q. v.), and in her acquisition of a clear moiety of the Eastern Empire, including Candia, the Morea, and three of the eight quarters of Constantinople. But these successes awoke the jealousy of Genoa (q. v.), and a doubtful contest of 130 years ensued, in which the annexation of Corfu poorly made up for the re-establishment of the anti-Venetian Byzantine Empire (1261). V. must now open up communication with Arabian powers, and so bring over Alexandria the wares of far Eastern lands, sought out by the enterprise of Marco Polo (q. v.) and other of her daring sons. In this she succeeded, but at home the government passed from a democratic to an aristocratic character (1286–1319), the *Serrar del Consiglio* excluding from the Grand Council all but the nobles of the Golden Book, and thus creating the haughty patriciate which 'reduced,' says Gibbon, 'the doge to a pageant and the people to a cipher.' Conspiracies against this dominant order led to the institution of a Council of Ten, the dreaded inquisitorial tribunal, rendered perpetual in 1335; and for the plot of

1355 even the Doge, Marino Falieri (q. v.), paid forfeit with his life. A war with Hungary cost V. her Dalmatian provinces (1358), but the annihilation of the Genoese fleet off Chioggia (1379) gave her the undisputed mastery of the sea, and contests with Padua and Milan during the dogate of Francesco Foscari (q. v.) extended her dominions on the Italian mainland, while Caterina Cornaro (q. v.) made over Cyprus to the republic (1489). But growth of dominion was dearly purchased at the decline of a commerce which, wounded by Turkish aggressions, received its deathblow from the Portuguese discovery of the Cape route to India (1498). Diplomacy broke up the formidable League of Cambrai, formed against V. by Emperor, Pope, and the Kings of France and Aragon (1508); but in spite of the glories of Lepanto (1571), and the gallant defence of Candia (1645–67), this island, like Nauplia, Cyprus, and the Morea, had passed in 1718 to the Turks. The degeneracy and secret terrorism, marked by external pomp, of V.'s last three centuries, are well exemplified by the eighty gaming-tables kept by patricians in 1735, and by the current maxim that 'courtesans could be usefully employed to ruin men whose wealth might make them dangerous.' The republic began with Attila, and ended with Napoleon, who in 1797 entered V., never trodden by hostile troops in all the preceding 1300 years. Ceded to Austria by the treaty of Campo-Formio, it was annexed to Italy (1805), but nine years later restored to the House of Hapsburg. The revolt under Manin (q. v.) was only suppressed, in spite of internal dissensions, after a siege of fifteen months, which cost the Austrians 20,000 men; and, finally, the Austrian reverses in the campaign against Prussia led to the incorporation of both city and territory with the kingdom of Italy, Victor Emmanuel making his entry 7th November 1866. See Daru, *Histoire de la République de Venise* (3 vols. Par. 1821; 4th ed. 9 vols. 1853); Ruskin, *The Stones of Venice* (8 vols. Lond. 1851–53; new and enlarged ed. 1874), and *St. Mark's Rest* (3 parts, Orpington 1877–79); Lorenzi, *Monumenti per servire alla Storia del Palazzo Ducale dal* 1253 *al* 1797 (vol. i. Ven. 1868); Baschet, *Les Archives de Venise* (Par. 1870); Romanini, *Storia di Venezia* (2 vols. Ven. 1875); Symonds' *Renaissance in Italy: The Fine Arts* (Lond. 1877); and Yriarte, *La Vie d'un Patricien de Venise au Seizième Siècle* (Par. 1874), and *Venise: Histoire, Arts, Industrie, la Ville, la Vie* (Par. and Lond. 1878); this last a splendid folio, embellished with 525 engravings.

Venlo', a town of Holland, province of Limburg, on the Maas, 19 miles N.W. of Viersen by rail. The town, which was fortified previous to 1868, is closely and irregularly built. It is the centre of the Krefeld, Maastricht, and Breda system of railways, and has manufactures of gin, cigars, and sewing-needles. Pop. (1870) 7754, mostly Roman Catholics.

Venn, Rev. Henry, born at Barnes, Surrey, in 1725, from a school at Bristol proceeded to Jesus College, Cambridge, where he graduated B.A. (1745), and obtained a fellowship at Queen's. After holding a Clapham curacy he became vicar of Huddersfield (1759), and rector of Yelling, Huntingdonshire (1770), which latter living he held till shortly before his death at Clapham, in June 1797. A founder of the Evangelical school in the Church of England, V. published *The Complete Duty of Man*, an *Examination of Priestley's Address on the Lord's Supper* (1769), *Mistakes in Religion* (1764), &c.

Veno'sa (anc. *Venusia*), a town of Italy, province of Potenza, 7½ miles E. of Melfi, is the seat of a bishop, has a castle, a cathedral, the ruins of a splendid abbey (Santa Trinità), with a monument of Alberada, first wife of Robert Guiscard, and old Jewish catacombs. Pop. (1871) 7222. V. is the birthplace of the poet Horace.

Ventila'tion. See WARMING AND VENTILATION.

Ventimi'glia, an Italian village, province of Porto Maurizio, on the Gulf of Genoa, 21½ miles E. of Nice by rail. It is a frontier town, and standing on a hill, has some military importance. Besides its castle, it has a cathedral and some Roman remains. The trade is in wine. Pop. (1872) 3518.

Vent'nor, an English watering-place on the S. shore of the Isle of Wight, and the southern terminus of the Isle of Wight railway, 11 miles S.E. of Ryde. It is picturesquely situated amid the charming scenery of the Undercliff, and with a warm southern exposure has become one of the most popular of English winter resorts. Among the attractions are the abundance of fossils and the beautiful beach of yellow shingle. V. has a good gas and water supply, excellent hotels, baths, reading-rooms, &c., and publishes a weekly newspaper. A new district church, of Holy Trinity, in Early Pointed style, was erected in 1862, and the National Consumption Hospital founded in 1872. Pop. (1871) 4841.

Ventric'ulites, a genus of fossil *Spongida*, or Sponges, characteristic of the Cretaceous or Chalk Rocks. *V. radiatus* is a familar species, occurring in the White Chalk. The V. were allied to the living deep-sea sponges known as *Holtenia*. They appear to have anchored themselves to the sea-bed by a bunch of fibrous roots.

Ventril'oquism (Lat. 'a speaking from the belly') is an art of speaking in such a manner that hearers are deceived into the belief that the sounds proceed from places other than that occupied by the ventriloquist. The term is incorrect, as the vocal sounds are produced by the *larynx* or organ of voice, but the expression of the face and movements of the lips and cheeks are restrained and modified so as to give the idea of the speaker being voiceless. One notable feature of successful V. consists in directing the attention of the hearers to the supposed quarter from which the sounds are to proceed; the performer being thus left unwatched to a great extent. In V. a long breath is first inhaled; this inspiration being slowly and gradually exhaled, and vocal power thus husbanded. There is no special qualification required for becoming a ventriloquist; long and continuous practice will ensure success.

Venue is the place to which a jury is summoned to try an action. It must be set forth in the plaintiff's pleading, and is usually in the county in which the ground of action lies; but the judge may change the V. asked for to another, either of his own accord or on the showing of the defendant that that other is a more desirable one. A criminal case must be tried in the county in which the crime is committed.

Ve'nus, popularly known as the 'goddess of love,' was originally an Italian goddess of the spring, and at a comparatively late period of Roman history became identified with the Greek Aphrodite, who in turn was only a modification of the Phœnician Ashtaroth, Asteroth, or Astarte. Hence various elements in her character and history. At times she appears as the goddess of the sky and of the moon (V. Urania), and at times as the goddess of the ocean; now she represents the general motherhood of nature; now she is regarded as especially the deity of wedded love, and now she serves as patroness for the impure gratification of sexual passion. According to the most popular form of her myth, she rose resplendent from the foam of the ocean, and after visiting Cytherea, landed on the shores of Cyprus, the island which was long the chief seat of her worship. Besides her son Eros (Lat. Amor or Cupid), she was accompanied by the *Charites* ('Graces'), *Himeros* ('Desire'), *Pathos* ('Anxiety'), and *Peitho* ('Persuasion'). She was married to Hephæstus (Lat. Vulcan), but proved a faithless spouse; her intrigues with Ares, her passion for the beautiful shepherd Adonis, and the favours she bestowed on Anchises, being scandalous incidents in her history. The dove, the ram, the hare, the dolphin, and the tortoise; the rose, the myrtle, and the apple were her principal symbols. Besides Paphus, Amathus and Idulian in Cyprus, Cytherea, Corinth, Carthage, and Eryx in Sicily, were chief seats of her worship. Her early introduction into Greece—when she was distinguished by such epithets as *Urania*, *Pandemos*, and *Anosia*—is proved by the presence of her symbol, the tortoise, on the earliest known Greek coins, those of Ægina. It was only in later times that she became popular at Rome, and this late popularity was mainly due to the connection established between the early history of Rome and the Trojan heroes. V. was naturally a favourite subject with the ancient poets and artists, and some of her statues are among the noblest remains of Greek and Roman sculpture. At first she was always represented as clothed, but after Scopas and Praxiteles it was common to dispense with drapery either partially or entirely, and at length in the hands of the baser sort of artists the goddess became little better than a naked woman, and was not even 'clothed on with chastity.' The positions and accessories are varied to an endless degree. Now she appears as *V. victrix*, holding a spear and treading on a helmet; now as if she had just risen from the foam of the sea (*Anadyomene*);

now as if she were leaving or entering the bath; now upborne by Tritons; now crouching (*V. accroupie*) as if to tie her sandal; now playing with Eros; now recumbent on her swans. Among the most famous of her statues are the V. of Cnidus by Praxiteles, only preserved to us in copies; the V. of Milo, so called from the island of Melos, where it was found in 1820, and the V. de Medici, which was dug up in several portions in the 17th c.

Ve'nus, the brightest and most beautiful of all the planets, is the second in order from the sun, if we neglect the dubious Vulcan. It thus lies within the earth's orbit, revolving round the sun at a mean distance of 66,134,000 miles in an elliptic orbit of eccentricity ·00686, which is inclined to the ecliptic at an angle of 3° 23′ 31″. Its sidereal period is 224·7008 days, or about $\frac{8}{13}$ths of our year. On account of this near commensurability of the periods of V. and the earth, a remarkable inequality exists, whose period is, according to Airy, about 240 years. The diameter of V. is estimated as 7510 miles. Hence the volume is ·855 of the earth's, and the density being a little greater than that of the earth, the mass is nearly the same as the earth's. On account of the excessive brilliancy of the surface of the planet, it is impossible to make accurate observations of it. The length of its day has, however, been fixed at 23 hours, 21 minutes, 22 seconds, and its axis of rotation is believed to be inclined at an angle of 74° to the plane of its orbit. With such an inclination the seasons on the planet must suffer extraordinary variations. Viewed through the telescope, V. presents phases like the moon. The full phase, however, being at superior conjunction, cannot be observed on account of the sun's excessive brightness. Consequently only a portion of its surface can be seen at any one time, and the brilliancy of the planet depends as much upon its distance as upon the amount of surface visible. The position of greatest brilliancy is at about 40° from the sun. The greatest possible elongation of the planet is 47° 12′, and hence V. is never seen at any great distance from the sun, but usually precedes or succeeds it by a brief interval of time. In the former case it is the *morning star*; in the latter, the *evening star*. At inferior conjunction, the dark side of the planet is turned towards us; and should the node of its orbit lie between us and the sun, the phenomenon known as the Transit of V. takes place. The planet then appears as a dark speck crossing the sun's disc; and being then at its nearest distance from the earth (some 25,000,000 miles), its parallax can be directly measured, and thus afford a means for calculating the parallax of the sun, one of the most important units in astronomy. This method of calculating the sun's distance was suggested by Halley, and was first successfully applied in 1769. These transits, however, are of very rare occurrence, recurring at intervals of 8, 122, 8, 105 years, so that four transits take place every 243 years. The last transit was in June 1874, the next will be in December 1882, and the next again not till June 2007. See SUN.

Ve'nus' Gir'dle (*Cestum Veneris*), the name given to a species of *Cœlenterate* (q. v.) animals, belonging to the highest group of that sub-kingdom—the division *Ctenophora* (q. v.). It appears in warm seas as a long, band-like animal, attaining a length of from 2 to 3 feet. At night it is markedly phosphorescent.

Ve'nus' Flower Basket (*Euplectella*) a beautiful genus of flinty or *Siliceous* Sponges, of which *E. aspergillum* and *E. suberea* are familiar species. It exactly resembles a delicate vase. The single large *osculum* forming the mouth of the sponge is covered by a kind of grating. The sarcode or horny matter is of brownish hue, and the flinty spicules are large. These sponges are found at the Philippine Islands, and are fixed to the sea-bed by a long coil of flinty fibres forming a kind of root.

Ve'nus' Fly'-Trap. See DIONÆA.

Ve'nus' Look'ing-Glass is *Specularia* or *Campanula speculum*, a favourite garden annual, native of S. Europe. The name was given from the resemblance of its pretty flowers set upon their cylindrical ovary to an ancient round mirror at the end of a straight handle.

Ve'ra, Cue'va de, a town of Spain, province of Almeria, on the Almanzora, near its entrance into the Mediterranean, 65 miles S.W. of Carthagena. It has an old Moorish castle, and a massive parish church, and produces pottery, wine, oil, &c. There are mines in the vicinity. Pop. 10,500.

Ve'ra Cruz', Vill'a Ri'ca de la ('rich city of the true cross'), the principal seaport of Mexico, and capital of a state of the same name, on the Gulf of Mexico, 190 miles E.S.E. of the city of Mexico by rail. It is surrounded by strong walls, and is further defended by two redoubts, and by the famous castle of San Juan de Ulloa, on an island of the same name, half a mile from the shore. The town is regularly and substantially built in the old Spanish style, the houses being variously coloured, and having balconies, arcades, and galleries. There are sixteen churches, a municipal palace, a custom-house, several hospitals, a library, a theatre, &c. The town is lit with gas and laid with tramways, while the supply of water has been recently augmented by the construction of works. The harbour is little more than an exposed roadstead, but a mole was completed in 1875. Many vessels are wrecked during the Nortes or north hurricanes, which sweep along the shore and deluge the town with sand-showers. Yellow-fever is the scourge of V. C., but it has been rendered less virulent by greater attention to sanitary conditions. More than half the trade of the republic passes through the port, the exports comprising precious metals, cochineal, sugar, provisions, indigo, sarsaparilla, logwood, jalap, vanilla, and pimento. The aggregate value of these in 1873 amounted to $17,939,000, and that of the imports, chiefly manufactured goods, to $14,114,000. The exports are mainly to Great Britain and the United States. Pop. (*Memoria del Ministro de Fomento*, 1877) 10,000. Founded by Cortes in 1519, V. C. was subsequently removed to Antigua, some miles to the N., but was brought back to its original site in 1590. The castle of Ulloa was held by the Spaniards till 1825, and both castle and city were bombarded and taken by the French in 1838. V. C. was besieged and captured by the United States army under General Scott in 1847.—The *state* extends along the Gulf in a narrow belt for nearly 500 miles, and is flanked by the Sierras, at a distance from the sea of some 30 miles. The coast tracts are sandy, are indented by lagoons, and are hot and malarious. Along the rivers, Panuco, Papaloapam, Goatzacoalcos, &c., there are fertile districts and rich pastures, while further inland rise the snow-clad volcano Orizaba, 17,176 feet high, the Cofre de Perote, near Jalapa, 14,309 feet, and Tuxtla, 9708 feet. This state is traversed by two railways, from the city of V. C. to Mexico and Jalapa respectively. Area, 26,232 sq. miles; pop. (1877) 504,950.

Ver'atrine, or **Verat'ria** ($C_{32}H_{52}N_2O_8$), a member of the group of organic bases known as the Alkaloids (q. v.), is obtained from the seeds of *Veratrum sabadilla*. It is insoluble in water, but dissolves in hot alcohol and in ether. *Colchicine*, extracted from *Colchicum autumnale*, was originally confounded with, but is now recognised as distinct from V.

Medicinal Properties of V.—V. is exceedingly irritating to any surface it may come in contact with. When taken internally in small doses, it lowers and weakens the pulse; in medium doses it produces gastro-intestinal irritation; and in large doses, violent vomiting, serous purging, often with intense burning in the mouth and throat, and general muscular weakness. At present, it is rarely employed except as a local application in cases of rheumatic neuralgia, narcotic poisoning, as an irritant applied to the spine, and to paralysed limbs. One-sixteenth of a grain has produced the most alarming symptoms. The only pharmaceutical preparation is *Unguentum V.*, and even this should be cautiously used.

Verat'rum. See HELLEBORE.

Verb (Lat. *verbum*, '*the* word,' so called because it is the most important word in a sentence) is the part of speech that affirms or asserts—*e.g.*, 'he is;' 'the sea roars;' 'Cæsar smote the Gauls.' An examination of these sentences, however, shows that while the V. in each case affirms, the extent and the mode of its affirmation are different. Thus, in the first example, mere existence is affirmed of the subject; in the second, action is affirmed irrespective of an object; in the third, the affirmation is limited by the introduction of an object. The classification of verbs gives expression to these differences. Three classes are enumerated—(1) Transitive; (2) Intransitive; (3) Neuter. A V. is transitive when the action it expresses 'passes over' to an object—*e.g.*, Cæsar *smote the Gauls*; it is intransitive when the action is confined to the actor, or at least does not refer to an object—*e.g.*, 'the sea *roars*;' and it is neuter ('neither') when no action at all but only a state or condition is expressed—*e.g.*,

'he *is*.' Verbs are modified to express Voice, Mood, Tense, Number, and Person. In highly-inflected languages such modifications are minutely carried out, and require great patience and perception to master and observe. In English they are of course extremely few. The 'voice' of a V. is that form which shows whether the subject of the affirmation or predication is the actor or the object acted upon. If the former, the V. is said to be in the *active*; if the latter, in the *passive* voice —*e.g.*, in the sentence, 'the sea roars,' the V. is active; in 'the body was thrown into the river,' it is passive. 'Mood' is the 'mode' or manner of predication. There are in English four moods—(1) the *Infinitive*, which is used to express a state or action free from any limitation of person, number, or time, *e.g.*, 'to err is human; to forgive, divine'; (2) the *Indicative*, which makes an affirmation without reference to any contingent circumstance, *e.g.*, 'they grew in beauty side by side;' (3) the *Subjunctive*, which is used to affirm not absolutely but contingently—*e.g.*, 'If I were not Alexander, I would be Diogenes;' (4) the *Imperative*, which includes various forms of predication by means of which we command, exhort, request, or supplicate—*e.g.*, 'Get thee behind me, Satan'; 'Stay, lady, stay, for mercy's sake.' Tense (from Lat. *tempus*, 'time') introduces into the affirmation of a V. the element of 'time.' Tense has a relation to the three divisions of time—present, past, and future; but to each of these the affirmation may stand in a threefold relation. The action predicated may be spoken of (1) as *Indefinite*—*e.g.*, I write, wrote, shall write; (2) *Imperfect*, I am writing, was writing, shall be writing; (3) *Perfect*, I have written, had written, shall have written. We have thus nine primary tenses. Number and person are also modifications of a V., for the purpose of showing whether the affirmation is made of one or more persons, and whether the speaker is making an affirmation about himself (first person), or about the person he is addressing (second person), or about some other person or thing (third person). In English, verbs are arranged for conjugation into two classes, the weak and the strong (see CONJUGATION). For details consult Mason's *English Grammar* (19th ed. 1874), and Bain's *Higher English Grammar* (Lond. 1874).

Verbena'ceæ, a large natural order of monopetalous dicotyledons, consisting of herbs, shrubs, and trees. It has been divided into three sub-orders:—(1) *Myoporineæ*, natives of Australia, S. America, and S. Africa; (2) *Verbeneæ*, natives of temperate and tropical America, and found also in Asia and Europe; and (3) *Selagineæ*, represented in Europe, but chiefly belonging to the Cape of Good Hope. The most important member of the order is Teak (q. v.). See also AVICENNIA. Many of the V. are fragrant and aromatic, some are bitter, tonic, and astringent, others are acrid. None enter into the British pharmacopœia. The order is familiarly represented in gardens by the verbena, and in hothouses by beautiful climbers belonging to *Clerodendron*. See VERVAIN.

Vercell'i, a city of Italy, province of Novara, on the Sesia, 13½ miles S.W. of the town of Novara by rail. In the unhealthy valley where it stands, wheat, silk, and rice are produced. It has handsome boulevards, a market-square with statue to Cavour (1864), a cathedral, with library of valuable MSS., ten other churches, including S. Christoforo, S. Andrea (1219), and S. Caterina, also two hospitals, and an institute of fine art. V. has manufactures of silk, wax, soap, candles, mirrors, and musical instruments. Pop. (1871) 20,140. Ruins of the ancient *Vercellæ* are still seen.

Vercell'i Book, a MS. volume discovered by Dr. Blume at Vercelli in 1823, which, in spite of its mutilated condition, is one of the most valuable relics of Old English literature, containing as it does not only six Saxon homilies, but also six poems which together amount to 7000 lines. A transcript of the poems, made by Dr. Blume for the Record Commission and still preserved by the Master of the Rolls, was printed as an appendix B to the report of the Commission for 1836. The two longest poems, the *Legend of St. Andrew* (3444 lines) and *Elene*, or *The Finding of the Cross* (2648), were published in German by Jacob Grimm, *Andreas und Elene* (Cassell 1840); and the former was again edited with a translation by Mr. J. M. Kemble for the Ælfric Society, 1845–46. The Early English Text Society made arrangements in 1874 for the publication of the homilies.

Ver'den, a town of Prussia, province of Hannover, on the river Aller, 2½ miles above its junction with the Weser, has a Gothic cathedral (1290–1490) and two other Evangelical churches, a Catholic church, and a gymnasium. V. has considerable trade, manufactures tobacco, cigars, and lucifers, and carries on brewing, fishing, and shipbuilding. Pop. (1875) 7669.

Ver'di, Guiseppe', an operatic composer, was born at Rancola, Parma, October 9, 1814. His first opera, *Oberto di San Bonifazio*, was produced at La Scala, Milan, on November 17, 1839. This was followed by *Nabucodonosor* (1842), *I Lombardi* (1843), and *Ernani* (1844), the last two of which made their composer's name celebrated throughout Europe. In the next five years, among other works, he composed the *Duc Foscari*, *Attila*, *Macbeth*, the *Masnadieri*, and *Luisa Miller*. In 1851 he produced *Rigoletto*, one of his most brilliant and finished efforts; and in 1853, *Il Trovatore* and *La Traviata*, which have proved more popular than any operas of equal age. His subsequent works include *Un Ballo in Maschera* (1858), *La Forza del Destino* (1863), *Don Carlos* and *Aïda* (1872), and *Montezuma* (1878). V. is the only worthy living representative of the Italian school of opera, into which he has infused a masculine nervousness and force wanting in the languishing and sentimental style of his immediate predecessors, Bellini and Donizetti.

Ver'dict, in law, is the finding of a jury upon the issue submitted to them. (See GUILTY; JURY, TRIAL BY.) In England, the jury must be unanimous. In Scotland, the verdict is according to the votes of the majority. When it will carry all the costs in a civil action and it is doubtful for which party it will be given, parties may agree to withdraw a juror; there is then no V., and each pays his own costs.

Ver'digris, a compound formed by exposing copper in air to the marc of grapes or other source of acetic acid, is a mixture of several basic acetates of copper which have a green or blue colour. By digesting powdered V. in warm water, a green insoluble part is left which contains a compound having the composition $Cu (C_2H_3O_2)_2 . 2 Cu O + 3$ aq. The soluble part crystallises on cooling and evaporation, forming a compound having the composition $2 Cu (C_2H_3O_2)_2 . Cu O + 6$ aq. By dissolving V. in hot acetic acid, and leaving the filtered solution to cool, dark-green crystals of the normal acetate of copper ($Cu (C_2H_3O_2)_2$ + aq) are formed.

Ver'diter, called also Bremen blue and Bremen green, is a hydrated oxide of copper used as a painter's colour. It is prepared from the subchloride of copper, and in proportion to the completeness of the oxidation of that substance so does the colour vary from a green to a peculiar greenish blue.

Ver'dun-sur-Meuse, a French town and fortress of the first rank, department of Meuse, on both banks of the river, 40 miles W. of Metz by rail. It is the seat of a bishop, and has a cathedral of indifferent merit, a large citadel, cavalry barracks, three hospitals, a public library, &c. The industrial products are spirits, liqueurs, woollens, confections, leather, ironwares, paper, and wine. Pop. (1876) 10,738. Anciently the chief town of the Celtic Verodunenses, and the *Verodunum* of the Romans, V. gave its name to the treaty of 843, by which the empire of Karl the Great was divided into the kingdoms of W. and E. Franks, the beginnings of the modern states of France and Germany. In the late war the Germans failed to take it by a *coup-de-main*, 25th August 1870, but forced it into capitulation by a regular siege extending from 13th October to 8th November 1870.

Ver'ger (Lat. *virga*, 'a rod,' lit. 'the rod-bearer') is an officer in cathedrals and collegiate churches who carries the mace, or symbol of authority before the dean on occasions of ceremony.

Ver'gil, Pol'ydore, a native of Urbino, studied at Bologna, and taking orders became chamberlain to Pope Alexander VI., who sent him to England to receive Peter's Pence (1501). In England he tarried fifty years, holding the rectory of Church Langton, Leicestershire (1503), and archdeaconry of Wells (1508), with prebends of Hereford and St. Paul's (1513), and returning to Italy in 1551, to die four years later at his native town. A slight dispute touching the priority of V.'s *Proverbiorum Libellus* (1498) to Erasmus' *Adagia* led to a life-long friendship between the authors; but V. is better remembered by his *De Inventoribus Rerum* (1499), edition of Gildas (1525), *De Prodigiis* (1526), and *Historia Anglica* (Basel 1534; 7th ed. Lond. 1651). A.

the first history where the facts and statements of earlier chroniclers were weighed and compared, and also by its choice Latinity, the last-named work merited the high value set on it by V.'s compeers. Sir Henry Ellis edited for the Camden Society the three last and first eight books of an old MS. translation of it in the British Museum (1844-46). See the Preface of Dr. W. A. Hammond's translation of the *De Rerum Inventoribus* (New York 1868).

Ver'gniaud, Pierre Victurnien, born at Limoges, 31st May 1753, settled as an advocate at Bordeaux in 1781, and on the outbreak of the Revolution was sent as a deputy to the Constituent Assembly, and afterwards to the National Convention, where his brilliant eloquence gave him a foremost place in the ranks of the Girondists. During the trial of Louis XVI. V. strove with all the power of his oratory to persuade the Convention to let the nation decide the fate of its former monarch, yet when it came to a vote he pronounced for 'death.' After the execution of Louis he became an avowed opponent of Robespierre and the party of the Mountain, was arrested 4th June 1793, and guillotined with twenty of his companions on the 21st of October following. See Barthe, *Les Orateurs Français* (4 vols. Par. 1820); Vermorel, *Œuvres de V., de Gaudet et de Gensonné* (Par. 1866), and Touchard-Lafosse, *Hist. Parlementaire et Vie Intime de V.* (Par. 1848).

Ver'juice, the expressed juice of unripe grapes, or the acid juice of crab apples. It is to a small extent used in the preparation of sauces, &c., and was formerly also employed in medicine.

Verme'jo, a leading tributary of the river Paraguay (q. v.) in S. America. It rises in the Andes, and has a S.E. course of about 600 miles, during the last 450 of which it receives no affluents. It is from 70 to 250 yards wide, and from 5 to 16 feet deep, with a moderate current, and is now regularly navigated. The name V., and its native appellation of Ypytá ('red water'), have reference to the colour of the stream, which tinges the Paraguay throughout its course below the confluence of the two rivers.

Ver'mes, the name given by Linnæus to all animals of worm-like shape, as well as to lower forms of animal life, irrespective of their appearance. At present some zoologists use it to designate the lowest group of annulose animals, while others include under it not merely the latter organisms, but the true *Annelida* (q. v.), or 'worms' properly so-called.

Vermicell'i, a fine thread-like form in which Macaroni (q. v.) is prepared.

Ver'mifuges. See ANTHELMINTICS.

Vermil'ion, or **Cinn'abar**, the red sulphide of mercury, is formed artificially by subliming an intimate mixture of 6 parts of mercury and 1 part of sulphur. The resulting compound (HgS) is then reduced to a very fine powder, thereby acquiring the beautiful bright-red colour peculiar to this pigment. The dull-red native Cinnabar is the most important ore of mercury.

Ver'min (from Lat. *vermis*, a 'worm'), a generic name given to the smaller animals which damage man's crops or other estate, or prey upon his domesticated animals. As thus used, V. includes the smaller mammalia and certain kinds of birds. It is unquestionably from the ranks of the quadrupeds that the great majority of 'V.' are drawn. Thus in gamekeeper's *parlance* all the weasel tribe—stoats, polecats, and weasels—are typical V. Hedgehogs are equally 'V.' in his eyes, because he believes they devour the eggs of game—a belief utterly without foundation. The destruction of hedgehogs, in fact, should be discountenanced, considering the service these animals perform in removing noxious insects. Rats and mice, especially field-mice and field-voles, may increase in such numbers as to destroy large quantities of grain, and thus become decidedly destructive 'V.,' while serious loss may also be caused to the farmer by hares and rabbits as well as by rodents. Amongst birds many of the *Raptores* are destructive to game. The falcons, hawks, and kites are 'V.' in this sense; so also are crows, owls, and magpies; but as the latter feed chiefly on mice and other small quadrupeds they are beneficial to man by repressing animals which are far more typically named 'V.' than themselves.

In the economy of nature a balance of power is rigidly observed, and in the maintenance of such a balance the so-called 'V.' play an important part. Too frequently a limited view of the range and functions of a particular animal or group of animals appears to warrant the supposition that extermination by man is necessary. In the majority of cases natural conditions—such as the changing seasons themselves, scarcity of food, or the great development of some special enemies of the race—suffice to repress a prolific species in time. There is thus little need for Malthusian measures and speculations in lower life; only it must be admitted that occasionally, and during the over-prolific period in the history of animal species, man requires to take measures for the repression of his lower neighbours. Agriculturists in particular, are beginning to recognise the truth of the statement that the birds which visit their fields are of extreme value in the repression of the insects and their larvæ which feed on the tender shoots of the grain. And even admitting that the fields may occasionally suffer from the visitation of common birds, the damage inflicted thereby is but trifling when compared with their services in repressing the insect species. Even the much persecuted mole has been shown by Darwin to be a thorough fertiliser of the ground, and the earth-worm itself acts in this way also. Both animals, in fact, by their operations in turning over the soil, in bringing fresh layers to the surface, and in breaking the clods, tend to open up the ground, and thus to ensure favourable conditions for the germination of the seed. And the despised and hunted rats may be shown, like the whelks and crabs of the sea, to play no unimportant part in nature's sanitary arrangements, by the wholesale destruction of offal and garbage in which they indulge. As *means of repressing V.*, traps and snares of various kinds are in use. Spring traps of ordinary kind, and the stamp traps with powerful teeth, are in use for the capture not merely of rats, but of foxes, weasels, and the like. Other traps, in the form of boxes, the entrance to which is closed by the act of the animal in entering, are also in use, and 'falls,' or traps in which a prop is pushed from under a box as the animal passes below to secure the bait, are well-known contrivances used in the capture, not merely of rats, but of larger quarry. Large numbers of field voles, &c., may be killed by digging shallow pits, these animals being unable to climb out (see VOLE). The *poisons* in common use for rats include arsenic and phosphorus. Rats may be suffocated in barns, &c., by the production of carbonic acid fumes, and by thoroughly closing the doors and windows for a day or two.

Vermont' (Fr. *ver mont*, 'green mountain'), one of the New England States of the American Union, bounded N. by Canada, S. by Massachusetts, E. by New Hampshire, from which it is separated by the Connecticut River, and W. by New York, three-fifths of the boundary being the shores of Lake Champlain (q. v.). Area 10,212 sq. miles; pop. (1870) 330,551. The surface is for the most part mountainous. A range called the Green Mountains traverses the state from N. to S., and divides near Killington Peak (4221 feet) at 44° N. lat. into two chains, of which the western extends in the same direction into Canada, and the eastern stretches in a N.E. direction into New Hampshire. The highest points are Camel's Hump (4088 feet), and Mount Mansfield, with its three summits, the Chin (4430 feet), the Nose (4094 feet), and the Forehead or South Peak (3934 feet), all in the western branch. The rocks are principally Metamorphic, consisting largely of gneiss. On the W. side of the mountains Silurian deposits prevail, with some beds of crystalline limestone overlying the sandstones; but on the E. side Silurian deposits give place to Devonian limestones, and these to strata of slate along the Connecticut River. Copper ores of considerable value occur, besides lead ores more or less argentiferous; and iron, in the form of chromic ores, hæmitite, magnetite, and bog ores. Excellent granite and slates are abundant, besides kaoline, steatite, fire-clay, talc, manganese, and limestone for burning. The eastern part of the state is drained by the Connecticut River and its feeders; the northern part sends small streams to Lake Memphremagog, of which one-fifth part lies within V.; the western portion is drained by the Missisquoi, Lamoille, Winooski, Otter Creek, Hubbardton Creek, and Poultney River, feeders of Lake Champlain; and the S.W. corner by the Hoosac and Battenkill affluents of the Hudson. The valley and meadow land of V. is generally fertile, and the mountain slopes afford rich and nutritious pasture. The principal trees are the fir, oak, hickory, beech,

birch, elm, cedar, juniper, and the sugar rock and red maples. The black bear, panther, lynx, and racoon are abundant, and the moose and elk are still occasionally found. The climate is healthy, though characterised by wide extremes. The mean annual temperature in the N.E. is 40°, in the S.W. and S. 46°. The average highest temperature in 1869 was 91°, the average minimum 29°, the average mean temperature 42·9°, the average annual rainfall 48·60 inches, the greatest amount falling in October. In 1870, V. had 4,528,804 acres of land, in farms of which 3,073,257 were under cultivation; the average size of the farms was 134 acres. The estimated value of the farms was $139,367,075, of all the farm products $34,647,027, and of wages paid $4,155,385. In 1874 the crops were estimated as follows: Indian corn, 1,660,000 bushels; wheat, 418,000; rye, 61,000; oats, 4,151,000; barley, 112,000; buckwheat, 372,000; potatoes, 4,782,000; tobacco, 105,000 pounds; hay, 973,500 tons; and were valued at $18,803,710. In 1875 the live stock was valued at $20,660,594, and consisted of 72,400 horses, 201,500 milch cows, 130,500 oxen, 516,400 sheep, and 52,400 swine. V., though essentially an agricultural state, has considerable manufactures, and ranked at the census of 1870 as 21st state in the Union in this respect. In that year it had 3270 manufacturing establishments, employing 18,686 hands, paying $6,264,581 wages, using $17,007,769 of raw material, and producing goods and wares valued at $32,184,606. The chief products were as follows: lumber, $6,186,660; woollen goods, $3,550,962; flouring-mill products, $2,571,594; leather, $2,012,513; scales and balances, $1,629,000; marble and stone work, $960,984; machinery, $756,080; furniture, $895,606; carriages and sleds, $839,029; hosiery, $551,129; boots and shoes, $547,789; cotton goods, $546,510; and agricultural implements, $523,669. In the year ending 30th June 1877, the imports into V. amounted to $3,688,824, and the exports to $1,338,376. In the same year there entered the ports of V. 675 vessels of 87,703 tons, and cleared 645 of 84,354 tons; while the mercantile marine of the state itself consisted of 5 steam vessels of 2520 tons, and 10 sailing vessels of 554 tons. In 1875 V. had 939 miles of railway. Education is in an advanced state. In 1876 there were 2519 common schools, maintained at a cost of $565,044; 26 incorporated academies and seminaries, 3 normal schools, and 61 other schools of higher grade, not connected with the public-school system. The capital is Montpelier (q. v.), the largest town, Burlington (q. v.). V. was not admitted to the Union until 1791, owing to disputes about the frontier line with New York. Her growth was rapid from that period until 1840, but has been almost stationary since. See H. Hall, *V. from its Discovery* (Alb. 1869).

Ver'nal Grass, Sweet Scented, is *Anthoxanthum odoratum*, one of the commonest British native grasses, and widely spread through Europe, N. Africa, and W. Asia. It is a perennial species, desirable in pastures on account of its early spring growth, and for the flavour that it imparts to hay. The pleasant smell of good new hay is derived chiefly from this grass (whence its specific name), and is dependent on a principle named *Cumarin* (q. v.).

Verna'tion, or **Præfolia'tion,** means the mode in which unexpanded leaves are disposed in the leaf-bud. V. varies considerably in different plants. Thus in firs we have a flat arrangement; in the cherry simply *folded;* in the beech with many folds, or *plicate;* in ferns, *circinate;* in grasses, *convolute;* and in other plants, *revolute, involute, contorted,* and *crumpled.*

Verne, Jules, a popular French story teller, was born at Nantes, February 8, 1828. After producing several comedies and operatic librettos he was fortunate enough to strike on the new vein of fictitious narrative which he has since worked with immense diligence and success. The main characteristic of his method is the continual employment of quasi-scientific material in the construction of his most fantastic and incredible creations. The most remarkable of these productions, which are, however, altogether lacking in pure human interest, are *Twenty Thousand Leagues under the Sea, From the Earth to the Moon, Across Africa in a Balloon,* and *To the Centre of the Earth.* Most of V.'s works have been translated into English and German.

Ver'net, Claude Joseph, a French painter, born at Avignon, 14th August 1714, was the son of Antoine V., a skilful decorator. When eighteen years of age, fired with artistic ambition he set out for Rome, where, though he soon surpassed his master Bernardino Fergioni, a noted painter of sea-pieces, it was some time before his merits were publicly appreciated. In 1745 he was made an associate of the Royal Academy at Paris, and in 1753, after an absence of twenty years, returned to his native country and was received a member of the Academy. Shortly afterwards he was commissioned by the king to paint a series of views of the ports of France, and it was nine years before he completed the task. 'J. V.,' says M. Villot, 'has neither the richness of tone nor the delicacy of execution of the Dutch painters; but he looks at nature in a broad, truthful, and simple way, and always renders it with an easy touch. The numerous figures introduced into his pieces were no mere irrelevant accessories, but gave interest and dignity to the scene. As he said of himself, there were painters who could better paint a sky, a piece of ground, or a wave, but there was no one who could make a better picture.' He died in the galleries of the Louvre, 3d December 1789. His youngest son, **Antoine-Charles Horace,** usually called **Carle V.,** was born at Bordeaux in 1758, studied at Rome, and in 1788 became a member of the Academy. He was mainly a battle-painter, but excelled also in comic genre-pieces, and was particularly successful in the treatment of horses and dogs. The 'Battle of Marengo' (1804) and the 'Morning of the Battle of Austerlitz' are among his more famous productions; for the latter he received from Napoleon the cross of the Legion of Honour. He died at Paris, 27th November 1836.—**Émile Jean Horace V.,** son of the preceding, was born at Paris, 30th July 1789, and studied under his father, the draughtsman Moreau, the architect Chalgrain, and the painter Vincent. At fifteen years of age he was able to maintain himself by his drawings, and he soon struck out into a style of his own quite different from that of the dominant school. This indeed at first stood in the way of his success, and made him lose the travelling scholarship of the Academy, but before long he managed to secure the patronage of the court. He served as a soldier, and in 1814 received from Napoleon the cross of the Legion of Honour for gallant conduct at the Barrière de Clichy. In 1826 he was elected a member of the Institute, and in 1828 he succeeded Guérin as director of the French Academy of Arts in Rome, a post which he retained for seven years. During the rest of his life he was frequently abroad, visiting Algeria, Egypt, Syria, England, and even Russia and the Caucasus; but he had an estate at Hyères, a house at Versailles, and apartments at the Institute. He was widely patronised, and honours of many kinds were heaped upon him. He died January 17, 1863. His only daughter and child, who had married Paul Delaroche, had died eighteen years before. The success of H. V. was largely due to the fact that he had a keen power of observation and an accurately retentive memory, that his execution was easy and rapid, and that he was restrained by no conventional restrictions from painting what he saw and as he saw it. His battle-pieces are full of the fierce motion of the fight. Among the vast multitude of works which he has left it is difficult to choose. The battles of Jemappes, Valmy, Hanau, and Montmirail (1817–23), the 'Barrière de Clichy' (1820), 'Mazeppa' (1825), 'Mazeppa and the Wolves' (1826), 'Cholera on Board the Melpomene' (1830), 'Judith and Holofernes' (1831), the 'Storming of Constantine' (1855), and the 'Battle of Isly' (1846), are among the twenty-two pictures which he exhibited at the Exhibition of 1855, and which procured him a grand medal of honour. See Durande, *Joseph, Carle, et Horace V.* (Par. 1865).

Ver'nier, a contrivance for measuring intervals much smaller than can be directly measured on a graduated scale. It was invented in 1631 by Peter Vernier, a Frenchman, and is now largely employed in graduated circles, barometer scales, &c. It consists, in its simplest form, of a small sliding scale, the graduated portion of which, equal in length to a given number of divisions on the principal scale, is divided into a number of equal divisions differing by one from the given number on the large scale. Thus if the chosen length on the large scale is divided into m parts, the V. of equal length is divided into $m + 1$ parts. Call this length a. Then each division on the large scale is $\frac{a}{m}$, and each division on the V. $\frac{a}{m+1}$. Hence if a dividing line on the V. is opposite a dividing line on the scale, the next line on the V. will fall short of the corresponding scale line by an interval equal

to the distance $\frac{a}{m} - \frac{a}{m+1}$, the next again will fall short of its corresponding scale line by twice this interval, the next again by thrice, and so on. But this difference is $\frac{a}{m(m+1)}$. Hence obviously by means of the V. we can measure intervals as small as $\frac{1}{m+1}$th of the smallest graduated interval on the scale. Thus, if it is desired to measure to hundredths of an inch, the V. must be made $\frac{9}{10}$ths of an inch long and then divided into 10 equal parts. Then the smallest measurable interval is $\frac{1}{10} - \frac{1}{10}$ of $\frac{9}{10} = \frac{10}{100} - \frac{9}{100} = \frac{1}{100}$. Instead of taking $m + 1$ V. divisions equal to m scale divisions, we may take $m - 1$. If it were desired to measure to hundredths of an inch on this modification, we should require to make the V. $\frac{11}{10}$ths of an inch long, and divide it into 10 parts. Then $\frac{1}{10}$ of $\frac{11}{10} - \frac{1}{10} = \frac{11}{100} - \frac{10}{100} = \frac{1}{100}$ is the smallest measurable interval. The practical method of using the V. will readily suggest itself when once the principle of its action is understood.

Ver'non, Edward, was born at Westminster, November 12, 1684, was well educated, and following a strong natural bent, entered the Royal Navy. He served in the battle of Vigo Bay, October 12, 1702, and with Sir George Rooke at Malaga in 1704, and soon got a captaincy. Made M.P. for Penryn (1727), and for Portsmouth (1734–41), he boasted in the House of Commons that he could take Porto Bello with six ships. Sent off with the specified number of vessels, he fulfilled his boast November 22, 1739. In 1741, however, he failed in his attack on Cartagena, but his popularity was undiminished, and he long represented Ipswich in Parliament. Smollett, who accompanied him to Cartagena, has immortalised the expedition in *Roderick Random*. In 1746 he was removed from the list of admirals, through a dispute with the Admiralty. He died at Nacton, Suffolk, October 29, 1757. V. published *A New History of Jamaica from the Earliest Account to the Taking of Porto Bello* (1740), and *Original Papers relating to the Expedition to Panama* (1744). See *The Life of Admiral V. by an Impartial Hand* (1758), and *Memorial from Contemporary Authorities*, by Wm. F. Vernon (1861).

Véron, Louis Desiré, a French journalist, born in Paris, 5th April 1798, took his degree of M.D. in 1823, and in 1824 received the appointment of physician to the royal museums, but in 1828 renounced his profession and obtained a post on the staff of *La Quotidienne*. He afterwards founded the *Revue de Paris* (1829), was director or lessee of the opera from 1831 to 1835, and acted as editor of *La Constitutionnel* from 1835 to 1856. In this last capacity he at first strongly supported M. Thiers, but after 1849 he became a partisan of the Bonapartes, and in 1851 loudly applauded the *coup d'état*. In 1852 he was appointed officer of the Legion of Honour. He died September 27, 1867. V.'s works are of interest and value for their piquant and pertinent details in regard to the social and political life of the times—*Mémoires d'un Bourgeois de Paris* (6 vols. 1854–56) and *Nouveaux Mémoires, &c.* (1866); *Cinq Cent Mille Francs de Rente: Roman de Mœurs* (1855), *Quatre ans de Règna: où allons-nous?* (1857); *Les Théâtres de Paris depuis* 1806 *jusqu'en* 1860 (1860).

Vero'na, an ancient city of N. Italy, province of the same name, picturesquely situated at the foot of the Tyrolese Alps, and on both banks of the Adige, 72 miles W. by N. of Venice by rail. It is a member of the famous Quadrilateral, having fortifications of unusual strength, and is interesting no less as a great centre of historical associations than as a celebrated home of art, rich in classical and medieval monuments of architecture. The Adige is here crossed by five bridges, and on the tongue of land on the W. side lies by far the greater part of the city. Foremost among the antiquities is the amphitheatre, probably erected under Diocletian (A.D. 284), and which brings out in its full perfection the massive grandeur of the true Roman style. It is 106 feet high and 528 yards in circumference, and rises in 45 tiers of grey marble steps, capable of accommodating 25,000 spectators sitting, and 70,000 standing. Most of the outside range of arches is lost, but the internal seats have been wonderfully preserved by a custom of repairing them which has gone on unbrokenly through all the ages, and which has become a part of the history of the building. Another antiquity, the great gate of V., the Porta de Borsari, now spanning one of the busiest streets, was erected by Gallienus in A.D. 265. Among other Roman remains is the Arco dei Leoni. In the architecture of V. there is a gap extending from the 3d to the 12th c. from the amphitheatre in the days of Diocletian to the church of San Zeno in the time of Friedrich Barbarossa. The latter edifice is the great example of what Freeman very aptly calls 'the barbaric form of Italian Romanesque.' The nave in its present form was begun in 1139, and the choir dates from the 13th c. A notable feature is the great Campanile; the projecting portal rests on lions of red marble, the interior has an open roof supported by fine pillars and columns. The cathedral of Santa Maria Matricolare is an imposing Gothic structure of the 14th c. At the portal are Roland and Oliver, the paladins of Karl the Great, and over the altar is a celebrated Assumption by Titian. The little church of St. Stephen on the E. or Theodoric's side of the river at one time disputed with the great *Duomo* the first place among the churches of V., as the seat of her bishops in life, and their resting-place in death. Other notable churches are the Gothic S. Anastasia (begun 1261), with marble façade; S. Giorgio in Braida (1604), designed by Sammichelfi, and adorned with pictures by Tintoretto, Veronese, &c.; S. Fermo Maggiore, of the 14th c., with rich interior; and S. Nazzaro e Celso, a work of the Renaissance. V. has many fine palaces, including the Palazzo del Consiglio ("La Loggia'), restored in 1873, with statues of famous Veronese, comprising Cornelius Nepos, Catullus, Vitruvius, the younger Pliny, Æmilius Macer, &c.; and the Palazzo Pompei alla Vittoria, now containing the Civic Museum and valuable picture-gallery. A unique Gothic structure is the tomb of the Della Scala family, who were presidents of the republic of V. for upwards of a century. On the left bank of the Adige rises the Castello S. Pietro, the stronghold of Theodoric, which was remodelled by Galeazzo Visconti in 1393, and which, after being dismantled by the French (1801), was refortified by the Austrians in 1849. The adjoining Giardino Guisti is noted for its venerable cypresses, some of which are over 400 years old, and attain a height of 120 feet. The seat of a bishop, a prefect, a tribunal, a commander-general, &c., V. has numerous educational and benevolent institutions. There is an important transit trade with Germany, and among the leading manufactures are silks, woollens, cottons, musical instruments, furniture, &c. Pop. (1876) 66,086. V. is one of the oldest towns of Italy, its earliest inhabitants being either the Euganei or the Celtic Cenomani. It became a flourishing colony under the Romans. Here Decius defeated the Emperor Philip in 249, Constantine overthrew the army of Maxentius in 312, and Stilicho hurled back the hosts of Alaric in 403. After his defeat of Odoacer (489) at V., Theodoric made it his alternative residence, and it was subsequently called Wälsch-Bern, or Dietrichs-Bern, to distinguish it from 'V. in montibus.' The city suffered during the Ghibelline wars, but prospered under the Scaligers (1262–1387), who were succeeded by the Visconti and Carrara families. It escaped the tyranny of hereditary rulers by transferring its allegiance in 1405 to Venice, whose fortunes it subsequently shared. See Perini's *Storia di V. dal* 1790–1822 (3 vols. Ver. 1873–75).

Verone'se, the name conferred on the great painter, **Paolo Cagliari,** from his birthplace, Verona, where he was born in 1530. A sculptor's son, he studied painting under an uncle, Antonio Badile, and was early summoned by Cardinal Gonzaga to decorate the cathedral of Mantua, where his 'Temptation of St. Antony' outdid the efforts of three fellow-artists from his native town. In 1555 he came to Venice, and entered upon his noble rivalry with Titian and Tintoretto, forming with them the mighty Venetian Trio, each of whose members preserved his own ideal—Titian pure loveliness, Tintoretto Titanic fury, V. material gorgeousness. His adornment of the church of S. Sebastiano with the 'Story of Esther,' of the Doge's palace with the 'Apotheosis of Venice,' and of the refectory of S. Giorgio-Maggiore with the matchless 'Marriage at Cana,' his winning with the allegorical 'Music' a golden chain awarded to the best design for the library of S. Marco, his journey to Rome in the ambassador Grimari's train, and his revisit to Verona—those are the scanty known facts in a career that closed with the painter's death at Venice, April 19, 1588, and with his burial in S. Sebastiano. But the life itself lives on his numberless vast canvases, where, be the subject sacred or profane, historic or allegorical, we see the scenes and men looked on by V. Thus

his 'Marriage at Cana' (now in the Louvre) contains portraits of himself, Tintoretto, Titian, and Bassano, as well as of François I., Karl V., Suleiman II., Vittoria Colonna, and Mary of England; another instance is furnished by the curious *procès-verbal* (1573), unearthed from the Venetian archives by M. Baschet in 1873. In it he justifies himself to the Inquisitors for introducing into a 'Last Supper' a jester with a parrot on his wrist, halberdiers, dressed in the German fashion, eating and drinking at the foot of a stately staircase, and one of the Apostles picking his teeth with a fork. Purple and fine linen, superb voluptuous dames, stalwart young signors, and crowded palaces, were V.'s *forte;* his paintings have all Rubens' pride of the eye, little of Rubens' lust of the flesh. Many were reproductions, thirteen depicting the 'Adoration of the Magi,' five the 'Entombment,' five the 'Crucifixion,' and four the 'Marriage,' while single masterpieces by him were the 'Rape of Europa,' 'Jupiter Fulminating against the Vices,' 'St. Jerome,' and the 'Supper in the House of Levi.' The National Gallery has six of his works—the 'Consecration of St. Nicholas,' a study for the 'Rape of Europa,' an 'Adoration of the Magi,' the important 'Family of Darius at the Feet of Alexander,' the 'Magdalen Laying Aside her Jewels,' and 'St. Helena: the Vision of the Invention of the Cross,' this last a splendid acquisition of 1878, well worth the outlay of over 3000 guineas. Among the disciples of V. were his brother Benedetto, his sons Carletto and Gabriele, and a nephew, Luigi dal Friso. See chap. vii. of Symonds' *Renaissance in Italy: The Fine Arts* (Lond. 1877), and Crowe and Cavalcaselle's *History of Painting in N. Italy* (Lond. 1871).

Veron'ica. See SPEEDWELL.

Veron'ica, St. See CHRIST, PICTURES OF.

Versailles, one of the finest and most famous cities of France, capital of the department Seine-et-Oise, 11 miles S.W. of Paris by rail. Standing on a plain, it is formed of broad, straight streets, intersected by elegant, tree-shaded avenues. Long the residence of the splendid court of France, it became the seat of the National Legislature in 1871. It is still the seat of a bishop, a prefect, an assize court, and a tribunal of the first instance; and, besides its grand historical palace, has many handsome private buildings, eight churches, including a cathedral, a Lutheran and an Anglican church, a theological seminary, a lyceum, an école normale (with botanical garden), a drawing-school, a school for German and English, a public library of 60,000 vols., a national museum, an old hospital (1350), &c. In former times V. flourished amid the luxury of its court, and even yet it is greatly dependent on the visitors who are attracted hither by the climate and surroundings, as well as by the lowness of its prices compared with those of Paris. There are, however, some manufactures of watches, arms, tools, iron and copper wares, Cashmere shawls, cotton goods, starch, needles, coloured papers, porcelain, &c. Pop. (1876) 49,847, including the garrison. The history of V. is that of its famous palace. The site was originally occupied by the priory of St. Julian, which dated from early Capetan times, and the first superior of which was *Hugo de Versallis*. In the 11th c. the priory was turned into a stronghold, and in 1627 was occupied as a chateau by Louis XIII. Reconstructed and enriched by Louis XIV., it continued to be a usual residence of the court down to the Revolution, the early scenes of which took place here in the meeting of the States-General in May 1789. Standing amid wide-spreading gardens adorned with fine fountains and statues, the palace is 1400 feet long by 260 broad, and contains valuable art collections. V. was the headquarters of the German army from 5th October 1870 to 13th March 1871, and in the great *Galerie des Glaces* King Wilhelm was proclaimed Emperor of Germany. The Legislature determined to remove its seat from V. to Paris by a vote of both chambers in March 1879. See Eckhard, *V. Ancien et Modern* (Par. 1840); Gavard, *Galeries Historiques de V.* (13 vols., Par. 1835-44); and Supplement (6 vols., 1847-49).

Verse (Lat. *versus*, from *verto*, 'I turn;' *cf.* Gr. *stichos*, 'a row'), in poetry, a line which, according to the nature, number, and arrangement of its feet, is termed an hexameter, pentameter, iambic, &c. V. also is sometimes used improperly for 'stanza,' or for 'poetry' generally. The versicular division of the Scriptures was confined in the oldest MSS. to such metrical portions as the Songs of Moses, Hannah, and Simeon; and its application to the whole Bible was adopted from the Masorites by the Dominican Sanctes Pagninus in his Latin translation (Lyon 1528).

Versecz', a town in the comitat of Temes, Hungary, 46 miles S. of Temesvar by rail, has several theological institutions in connection with the Greek Church. Silk, wine, and rice are the chief products, the annual supply of wine exceeding 11,000,000 gallons. Pop. (1869) 21,095. On 19th January 1849, V. was the scene of a severe defeat inflicted by General Todorovich upon the Hungarian insurgents.

Verst, a Russian measure of length, equivalent to 3500 feet, or about two-thirds of an English mile.

Vert. See HERALDRY.

Ver'tebra. See SKELETON, SKULL, and SPINE.

Ver'tebral Col'umn. See SPINE and SPINAL COLUMN.

Vertebra'ta, the highest sub-kingdom of animals, including the fishes (*Pisces*), frogs, &c. (*Amphibia*), reptiles (*Reptilia*), birds (*Aves*), and mammals or quadrupeds (*Mammalia*). The most characteristic of the features by which V. are distinguished from Invertebrata (q. v.), are the specialisation of the chief nervous centres, and their peculiar relation to the other systems of the body. See DEVELOPMENT OF EMBRYO.

Verti'go, in medicine, designates a sensation of giddiness without loss of consciousness. Two kinds of V. are described, one depending upon visceral irritation and another upon a morbid condition of the auditory apparatus. The first, which is termed *Stomachic* V., is probably dependent upon a reflex excitation of the cerebral vessels from some visceral irritation, and frequently occurs after a hearty meal, though sometimes when the stomach is entirely empty. There is first slight headache, buzzing in the ears, palpitation, sometimes hallucination, followed by giddiness. Tape-worm (q. v.) is a frequent cause of V. For the treatment of stomachic V. Trousseau recommends a glassful of quassia infusion every morning, and after each meal a powder containing bicarbonate of soda and calcined magnesia, five grains of each, and ten grains of chalk powder. Strychnia, pepsine, and bismuth may be given also. *Auditory* V., sometimes called Ménière's disease, is a morbid cerebral condition expressed by V. and rotatory motions dependent upon disease of the labyrinth, or other parts of the central auditory apparatus. Ménière was the first to describe the disease. There are generally some prior indications of otitis, a sensation of nausea and buzzing in the ears. The patient sways or reels, and there is a tendency to turn from the left to right when the left ear is affected, and *vice versa* when the other ear is affected.

The pathological conditions giving rise to *auditory* V. have been recently investigated by Flourens, Goltz, Brown-Sequard, and still more recently by Ferrier and Crum-Brown. Brown-Sequard illustrates the relation of rotatory movements to auditory irritation as follows:—'(1) Any one who has received an injection of cold water in the ear may know that it produces a kind of V., and that it is difficult to walk straight for some time after this irritation. (2) A sudden noise makes the whole body jump, particularly in old people, or in persons attacked with anæmia, chlorosis, epilepsy, chorea, hysteria, hydrophobia, and in certain cases of poisoning; in a word, in all circumstances in which the control of the will over reflex actions is lost or diminished. (3) V. and various convulsive movements in cases of irritation of the acoustic nerve have been observed in adults and children. Rotatory movements have taken place in cases of suppurative inflammation of the ear, and twice immediately after an injection of nitrate of silver.' A perfect condition of the labyrinth is necessary to the preservation of the power of equilibrium, as it seems to regulate that condition, and to preside over co-ordination. See *Leçons sur les Maladies du Syst. Nerv.*, No. 4, by M. Charcot; *On the Functions of the Brain*, by Dr. Ferrier (Lond. 1876); *British Medical Journal*, August 26, 1876, and March 16, 1878; *On Deafness, Giddiness, and Noises in the Head*, by Edward Woakes (Lond. 1879).

Ver'tue, George, an English engraver and antiquary, was born in Westminster in 1684, studied under Michael Vandergucht for seven years, and in 1709 started in business for him-

self. His first patron was Sir Godfrey Kneller, who warmly befriended the young artist. An engraved portrait of Archbishop Tillotson at once secured him a high reputation. Another of George I. issued immediately after his accession was extraordinarily popular. In 1717 he was elected engraver to the Society of Antiquaries, and worked in their service till his death, 24th July 1756. V.'s engravings, which are very numerous, are historically valuable on account of their accuracy, but they lack spirit. An enthusiastic antiquary, he made frequent journeys through England to draw churches, monuments, and ruins. For more than forty years V. was engaged in collecting materials for a *History of the Arts in England*, which came into the hands of Horace Walpole, and were copiously used by him in his *Anecdotes of Painting in England* (5 vols. 1762). A complete list of his works—the portraits alone are upwards of 500—will be found in Walpole's *Catalogue of Engravers*.

Vertum'nus. See POMONA.

Ver'vain (*Verbena*), the type-genus of *Verbenaceæ* (q. v.), consisting of about 80 species of herbs or undershrubs scattered over tropical and sub-tropical regions, especially those of the New World. *V. officinalis*, the only representative of the genus and of the order belonging to the British flora, is a local plant of dry waste ground in the English counties. This species was an object of much superstition among the ancients—Persians, Greeks, Romans, and Druids—and was supposed to possess remarkable virtues. Various species, and innumerable gardeners' varieties, of *Verbena* are extensively cultivated as ornamental plants or for their fragrance, such as *V. chamædrifolia* from S. America, and *V. triphylla* or *Aloysia citriodora*. The 'oil of verbena' of perfumers, so much prized for its lemon-like scent, is extracted from a grass, and not, as its name implies, from a species of V.

Ver'viers, a town of Belgium, province of Liege, in the valley of the Vesdre, 16 miles E.S.E. of Liege by rail. It consists of an upper and a lower town, is regularly built, and has a fine town-house, a theatre, a large public library, and a picture-gallery. V. is the frontier station of the Rhenish and Belgian railway, and, as the centre of the cloth manufacture, may be called the Leeds of Belgium. Besides its extensive cloth and cassimer manufacture, it has wool-carding and dyeing, soap and vitriol boiling, tanning, brewing, machine-making, and metal-founding. Pop. (1874) 47,311.

Ver'wick, a town in the province of W. Flanders, Belgium, close to the French frontier, and 10 miles N.W. of Courtray by rail. It has large tobacco manufactures. Pop. (1870) 6758.

Vesa'lius, An'dreas (the Latinised form of **André Vesale** or **Wesel**), one of the great founders of modern anatomy, was born at Brussels, December 31, 1514. Educated in grammar at Louvain, he began his anatomical studies at the age of fourteen under Dubois at Paris; and so rapid was his progress that in his twenty-second year he was asked to demonstrate publicly in the university of Padua. At length the result of his labours, carried on at Venice, Pavia, Bologna, Pisa, and Basel, appeared at Basel in 1543 as a folio volume illustrated with plates, *De Humani Corporis Fabrica*. Soon afterwards called to be physician to Karl V., he accompanied the emperor on his journeys and campaigns; and on Karl's abdication he passed into the service of Philip and settled at Madrid. Here, however, he was more than ever exposed to the attacks of his professional opponents, and at length he was brought before the Inquisition and condemned to death. The influence of the king secured his pardon on condition that he undertook a pilgrimage to the Holy Land. On his way back in 1564 he was wrecked on the island of Zante, and died in such penury that he was indebted to the charity of a stranger for his burial. Not only did V. make many important discoveries and correct many errors in his favourite science, but he greatly accelerated its progress by relieving it from the trammels of the Galenian traditions, and by substituting the dissection of the human body for that of the lower animals. His *Opera Omnia* were published by Boerhaave and Albinus (Leyden 1725), and his Life has been written by Burggrave (Ghent 1841), Mersman (1845), and Weynants (Löuv. 1846). His *Tabulæ Anatomicæ Sex* (Ven. 1538), the first contribution which he made to the popularisation of anatomy, were reproduced by lithography for Sir William Stirling-Maxwell in 1875. A contemporary portrait of V. was discovered in the Louvre in 1876.

Ves'ica Pis'cis (Low Lat. 'bladder-fish'), the name applied by Albert Dürer to an almond-shaped or pointed oval figure, such as was sometimes given to aureoles, medieval seals, and window traceries. English antiquaries have conjectured that the name was due to a supposed resemblance of the figure to the symbolical fish or Ichthus (q. v.).

Vesicula'ria, a genus of Lower *Mollusca* or *Molluscoida* (q. v.), belonging to the *Polyzoa* (q. v.), included in the group *Ctenostomata* (q. v.). In this group, the cells of which the organism is composed arise from a common tube, and the cell mouths are terminal in position.

Vesoul', capital of the department of Haute-Saône, France, on the Dugeon, at the foot of Motte-de-V., 74 miles S.E. of Chaumont by rail. It is well built, with wide streets. A church of 1745 and the *Palais de Justice* (1765) are the principal buildings. There is a public library, with 26,000 vols. V. has tanneries, turning-mills, basket manufactories, weaving, and trade in salt, but agriculture is the main industry. Pop. (1872) 6313.

Vespasia'nus, T. Flavius Sabinus, a Roman emperor, was born near Reate in the Sabine country, November 17, A.D. 9. Previous to his consulship in 51 he had successively filled the posts of military tribune in Thracia, of quæstor in Crete and Cyrene, and of commander of a legion in Germany and Britain (A.D. 43). Under Nero he was proconsul in Africa, and in 66 he was despatched by this emperor to carry on a war against the Jews. On Nero's death (68) the throne was held in rapid succession by Galba, Otho, and Vitellius. The last of these was hardly secure of his position when V. came forward as his rival, and supported as he was by the legions of the East he soon carried all before him. Rome was seized by his generals, and in December 21, A.D. 69, Vitellius was put to death. The reign of V. is remarkable in three distinct aspects—as a period of military glory, of architectural splendour, and of literary culture. There were three great wars, the war with Civilis in Germany, the war with the Jews, and the war in Britain, and in all three the emperor was served by able generals. The German leader was finally defeated (70) by Cerealis; in the same year the city of Jerusalem was captured and laid waste by Titus, the emperor's own son; and before the close of the reign Agricola had subdued the British as far N. as the Tyne and the Solway. In 71 the temple of Janus was closed, and V. began to build his celebrated Temple of Peace; and though it was not completed till the reign of Domitian, it is to V. that the chief credit is due for the matchless Colosseum or Amphitheatrum Flavianum. Tacitus and Pliny are the two great writers of the period. Of his humble origin V. was never ashamed, and to the last he showed affection for the scenes of his early days. He died 24th June, A.D. 79, and was succeeded by his son Titus. An interesting relic of his reign is the *Lex de Imperio Vespasiani* or *Lex Regia*, by which the empire was formally placed in his hand by the Roman senate, the bronze tablets of which, discovered in 1347, are now in the Capitoline Museum. It was on this law that the Roman revolutionary, Rienzi, professed to found some of his claims. See A. G. Cramer, *F. V.* (Jena 1875).

Ves'pers, so called from Vesper, the evening star, was also called *hora lucerna* ('lamp hour'). Originally, like that of all the Canonical Hours (q. v.), of which at first it was the last, the service consisted of the singing of three psalms intermixed with some prayers. According to the account of all the services given in the Apostolic Constitutions, that for V. opened with the 140th (141st) Psalm, which was followed by a prayer. A collect was next said by the bishop, and a benediction pronounced on the people, who were then dismissed. But different churches had different usages, and in some, lessons were read, hymns sung, and other prayers offered.

Vespertil'io. See BAT.

Vespucci. See AMERIGO VESPUCCI.

Ves'ta, an ancient goddess, was called Hestia by the Greeks. According to the traditions of that people she was a virgin divinity, and watched over the fire that burned on the household hearth, which was looked upon as her shrine. Something sacred attached to this part of the house. It was the family altar; here suppliants took refuge; on it oaths were sworn. Each town had its public fire, which was left continually burning in the Prytaneum; and when a band of colonists went forth from

the city, they carried fire lighted at the common hearth with them. At Rome it was believed that Æneas had brought in this manner the sacred fire from Troy. It was preserved in a temple of circular shape with vaulted roof, which stood on the Forum. The sacred fire therein was tended by six priestesses who were called *Vestales*. They were virgins like the goddess whom they served. They performed several important functions in the state religion of Rome. They assisted at all great public rites, and were present at such religious transactions as the consecration of temples. Their fixed term of service was thirty years, of which they passed ten in a state of noviciate, ten in performing the sacred duties of their office, and ten in instructing novices. After this they were permitted to return to ordinary life if they pleased, though this was a privilege of which few availed themselves; for notwithstanding the drawbacks and restrictions of their position, it was one of great honour and even profit. Lictors preceded them when they appeared in public; consuls and prætors saluted and made way for them. They were maintained at the public expense, and they occupied special places of honour at the public games. If any proved unfaithful to her vows, she met with a terrible fate. She was degraded and deprived of her insignia of office. She was then dressed like a corpse, placed in a close litter, and conducted with all the usual ceremonies attendant on a funeral to a piece of ground called the Campus Sceleratus, where she was buried alive. If the sacred fire of the goddess was allowed through negligence to go out, it was rekindled by the Pontifex Maximus by the friction of two pieces of wood against each other. The festival of V. was celebrated on the 9th of June in each year, on the 15th of June the temple was cleaned and purified, and on the 1st of March the sacred fire and the laurel tree that shaded it were renewed.

Vest'ments, Sa'cred. Ministers of religion have everywhere, and at all times, been distinguished by some peculiarity of dress. In the Christian Church the first garment that began to have something of a distinctive nature was a mantle whch was generally worn by philosophers and their disciples, and was adopted by Christian ascetics—*pallium asceticum* (see PALL)—but the use of which was given up in the 6th c. In the 5th c. mention is first made of a 'religious habit,' or a special dress for the clergy. They were still more clearly distinguished from the laity during the 6th c., when the latter began to imitate, in the style of their dress, the barbarians who had overrun Europe, while the clergy generally preserved the more grave and dignified Roman costume. As regards special garments to be worn by the clergy while engaged in discharging their peculiar functions in the conduct of public worship, &c., a distinction gradually arose between them and the common dress of the laity simply by the avoidance of new fashions and the use of richer materials. (See CHASUBLE, DALMATIC.) From the 4th c. to the 9th c. the material of which they were made was for the most part white; after that other colours were gradually introduced, and after the 11th c. the five colours were definitively adopted which are used to the present day—white, red, green, violet, and black. The S. V. worn by priests in the Roman Catholic Church at the celebration of Mass are six in number—the Alb (q. v.), Amice, Cincture, Maniple, Stole (q. v.), and Chasuble (q. v.). See Martigny, *Dict. des Ant. Chret.* (new ed. Par. 1877).

Ves'try. See PARISH.

Vesu'vian, or **I'docrase**, a mineral originally detected in the volcanic débris of Mount Vesuvius, is very closely allied to the garnet, agreeing with it in chemical composition, but differing in the form of its crystals. It is a silicate of lime and alumina; specific gravity 3·3, and hardness about 5·5. In colour it varies from green to dusky brown, and specimens of the latter hue are sold in Naples under the name of *gemmes de Vesuve*.

Vesu'vius, of all volcanoes the most famous in history, rises a solitary peak from the Campanian plain, which stretches along the N.E. shore of the Bay of Naples in Southern Italy. It lies nearly due E. of the city of Naples, and its western slope rises from the sea at an angle of 10°. The central cone, with a gradient of from 30°-35° and a height of nearly 4250 feet, is separated by the *Atrio del Cavallo*, a deep sickle-shaped valley, from *Monte Somma*, a crescent-shaped ridge on the N.E. of the mountain. Monte Somma attains its maximum height in the *Punta del Masone* (3642 feet), rising abruptly from the Atrio del Cavallo, but sloping gradually down to the plain on the N. Eighteen centuries ago V. presented a very different appearance from what it does now. The slopes were clothed with verdure and covered with vineyards. There was no cone, but the summit, mainly level, was sterile and charred, suggesting to Strabo the geographer, to whom we are indebted for our knowledge of its appearance, its probable volcanic origin. Within sixty years after his death, in the year 79 A.D., the first known eruption occurred, devastating the country for miles round, and completely overwhelming in ashes and lava Pompeii (q. v.), Herculaneum (q. v.), Stabiæ, and other villages of the district. Of the subsequent eruptions, which have continued to take place at intervals, the most violent were those of the years 203, 472, 512, 685, 982, 1036, and 1139. Between 1500 and 1631, V. was in a state of quiescence, but in December of the latter year a terrific eruption occurred, projecting stones and ashes to great distances, and pouring down lava streams upon the villages which nestled at the mountain's base. Other eruptions followed in 1638, 1660, 1680, 1707, 1737, 1760, 1767, 1779, and 1794, during which succession of disturbances the summit underwent marked alterations in aspect. The eruption of 1794 was remarkable for its lava streams, many of which poured into the sea, heating the water to a considerable extent. During the present century eruptions have taken place in 1804, 1805, 1822, February 1850, May 1855, June 1858 (when the cone sank 195 feet below its former elevation), December 1861 (when Torre del Greco was again devastated), and November 1865. This last one was comparatively mild, and came to an end in November 1868. In January 1871 the mountain began to show symptoms of a renewal of disturbance, and early in the succeeding year the eruption gradually increased in violence till April 14, when lava burst forth on all sides, one tremendous stream being 1000 yards wide and 20 feet deep, and flowing in 12 minutes to a distance of three miles. A detailed account of this eruption has been published by Palmieri, the director of the Meteorological Observatory, which is built on a shoulder of the hill at a height of 2218 feet above the sea-level. In 1877 the mountain, after a period of complete quiescence, began to emit fire and flames, and has continued to do so with varying activity for over two years. In October of 1878 the eruption attained a maximum, but was unaccompanied by any of the horrors which characterised that of 1872. At present there are indications of increased activity. A scheme, proposed by a Neapolitan banker, for constructing a railway from Naples to the margin of the crater, has lately been adopted and put into execution. The waggons, which are each to contain 16 persons, will be dragged up the incline by means of a rope, and will be provided with a patent brake for stopping them instantly should the rope happen to break. See Phillip's *History of V.* (1869), Palmieri's *Eruption of V.* (1872), and Rath's *Der V.* (Berl. 1873).

Veszprim (Ger. *Weissbrunn*), a town of Hungary, at the N. end of Platten See, 22 miles W. of Stuhlweissenburg by rail. In the centre of the town is a precipitous chalk hill, which formed a valuable fortress in the wars with the Turks. On this hill are the cathedral, a magnificent building of the 14th c., and the episcopal palace with the chapel of Queen Gisela. V. has also a gymnasium, a college of the Piarist monks, and a tall minaret—the only relic of Turkish occupation. Breweries, corn-mills, flannel-weaving, spinning, and iron-works are the chief industries. The vine is cultivated. Pop. (1869) 12,100. V., which under the Romans had the name of *Cimbriana*, was once a royal residence. The Hungarians took it in 1491, the Turks in 1552, and it was joined to the empire in 1683.

Vetch, or **Fetch,** or **Fitch,** used absolutely, means the fodder-plant *Vicia sativa*, but serves also as an English name for the genus *Vicia*. This genus, belonging to the *Papilionaceæ* suborder of *Leguminosæ*, consists of about 100 species of climbing or diffuse herbs, distributed through temperate regions of the N. hemisphere and S. America. The common Bean (q. v.) is frequently classed under *Vicia* as *V. Faba*. The next most important species is the V., or Tare of agriculturists—the *V. sativa* above mentioned. It is one of the best fodder-plants, but is only of one or two years' duration; it is important also for green-manure, and as a companion-crop with clovers. The practice of sowing it along with oats or barley is strongly recommended, insuring a greater bulk of produce, and preventing the crop from massing and rotting in wet weather. *V. Cracca*, or the tufted V., *V. peregrina*, *V. sepium*, *V. sylvatica*, and various species of

the same group as *V. sativa*, are all relished by cattle, and some of them are cultivated in S. Europe. Twelve species of *Vicia* (including therein *Ervum*) are natives of Britain. See TARE.

Vetch, Bitter. See OROBUS.

Vetch'ling. See LATHYRUS.

Vet'eran, an old soldier. The word is derived from *veteranus*, a soldier in the Roman militia who had served several campaigns, and who was therefore entitled to certain benefits and privileges. In modern usage it is applied very similarly—viz., to soldiers who have retired from the army after long service, and who are only liable to be called up in case of national emergency. V. corps form useful adjuncts to the military power of a country, and are particularly suited for garrison duty, and for supplying at home the place of the army in the field.

Vet'erinary Med'icine (Lat. *veterina*, 'beasts of burden') may be defined as that branch of medical science which embraces the treatment of diseased domestic animals, and the preservation of their health. V. M. has evidently been practised from the earliest times; and there is every reason to suppose that the study of disease in the inferior animals was applied, on comparative principles, to the treatment of disease in the human subject. For many centuries, the inferior animals alone were used for purposes of scientific dissection. Among the Greeks, the study of the diseases of domestic animals, and of the remedial agents applicable to such diseases, was directly applied to the practice of medicine, and it was compulsory on anyone making a new discovery regarding such curative agents, to divulge it for the public good. Physicians were presumed to be acquainted with V. M., and Hippocrates, the most celebrated physician of early times, wrote a treatise on the curative treatment of horses. Columella (q. v.) and Vegetius, Latin authors, the latter of whom flourished about 300 A.D., wrote books on V. M., which contain an epitome of the best of all that was previously known. In the Middle Ages, however, V. M. was utterly neglected, and desolating plagues swept away nearly the entire herds and flocks of the countries they visited, precisely as the great epidemics of the Middle Ages swept away vast numbers of human beings, almost depopulating many of the provinces of Europe. Indeed, cattle-plagues were not infrequently the forerunners of great epidemics, and although they may have had no connection as cause and effect, they may have had some co-relation, as affecting the food-supplies of human beings and ushering in periods of famine, which would give intensity to epidemic diseases. During the 16th c. V. M. became again a subject of study, and the Constantine collection of works were translated from the original Greek into Latin by the order of François I., and from the Latin they were soon afterwards translated into Italian, French, and German. During the 17th c., the more important works which appeared were Fiarchi's Italian treatise on *Horsemanship*, and the *Infermita e Suoi Remedii, del Signor Carlo Ruini*, published in Venice, 1618. In 1654 the *Grand Marſchal François* was published; and, towards the close of the century, the elaborate work of Sollysel. In Great Britain, Blundeville and Gervase Markham published works on farriery; and Snape, farrier to Charles II., published an anatomical treatise on the horse, his plates being copied from those of Ruini. The 18th c. produced numerous authors on V. M., more especially in France, an impetus having been given to the study by the establishment in 1761, under royal patronage, of the Veterinary Seminary at Lyon under Professor Bourgelat. In 1766 another school of V. M. was opened at Alfort, near Charenton; and others were subsequently opened at Strassburg and Montpelier, and in almost every European city of note, as Vienna, Dresden, Leipzig, Berlin, Copenhagen, Prague, Munich, Hanover, Naples, London, &c. In 1754 La Fosse, a contemporary of Bourgelat, published his numerous memoirs in one volume, which was soon afterwards translated into most of the European languages. The most celebrated French writers of the beginning of the present century are Chabert, Flandrin, Gilbert, Vicq-d'-Azyr, and Huzard. In the reign of George I., Sollysel's work was translated from the French into English by Sir William Hope; and, about the middle of the last c., Gibson, who was formerly surgeon to a regiment of cavalry, published his treatise on farriery, the best which had then appeared in the English language. The other writers on V. M. of this period are Bracken, Bartlet, and Osmer, who had been educated as medical practitioners.

In 1791 the Veterinary College of London was instituted under the presidency of the Duke of Northumberland. During the present reign a charter has been granted to the veterinary body at large, forming a Royal College of Veterinary Surgeons, empowered to examine candidates and grant diplomas. In 1819 the first course of lectures on V. M. in Scotland was delivered by Mr. Dick, and a systematic course under the auspices of the Highland and Agricultural Society and the Senatus Academicus of Edinburgh in 1823. At his death, in 1866, Mr. Dick bequeathed to the city of Edinburgh his entire fortune, to be devoted to the teaching and improvement of V. M. In 1857 Mr. John Gamgee established a new veterinary college in Edinburgh; and since 1861 a veterinary school has been conducted in Glasgow by Mr. James Macall.

Previous to entering a veterinary college a matriculation examination must be passed in English reading, English grammar, writing to dictation, and arithmetic; and, in addition to these subjects, candidates may be examined in Latin, Greek, French, and German if they wish. During the first year, lectures and demonstrations are received in chemistry, toxicology, materia medica, pharmacy, botany, and also in anatomy; during the second year, in general and special anatomy, physiology, histology, medicine and surgery, and dissections; and during the third year, in V. M. and surgery, demonstrations on morbid anatomy and pathology, clinical and general instructions. At the end of each session the student has to undergo a searching professional examination. The following are the more important works recently published on V. M.: *Handbuch der Veterinär-Polizei*, by Haubner (Dresden 1866), *Lehrbuch der Pathologie und Therapie der Hausthiere*, by Röll (Vienna 1860), *Nouveau Dictionnaire Pratique de Médicine, &c. Veterinaires* (Par.), *Principles and Practice of Veterinary Surgery*, by Professor Williams (Edin. 1872), *The Anatomy of the Domesticated Animals*, by M. Chaveau, translated by Mr. Fleming (Lond. 1873), *Animal Plagues*, by Mr. Fleming (Lond. 1871), *Manual of Veterinary Sanitary Science and Police*, by Mr. Fleming (Lond. 1875), *Veterinary Obstetrics*, by Mr. Fleming (Lond. 1878).

Vet'erinary Sur'geon. The class certificates of the recognised veterinary colleges qualify for examination for the diploma of the Royal College of Veterinary Surgeons, the Highland and Agricultural Society's veterinary certificate for appointment in the army and Government portal inspectorships in England, Scotland, and Ireland. A V. S. in the army is an officer of a cavalry regiment, or in the artillery, who is charged with the supervision of the horses, and with their treatment when sick. Previous to admission he is required to produce evidence of qualification, and to pass an examination. On appointment he receives 10s. a day, and ranks as lieutenant. By length of service and efficiency the pay may rise to £1, 3s. a day, and he may advance to the rank of major, and after twenty-five years' service he becomes entitled to retire on half-pay.

Vet'iver or **Kuss-Kuss** is the fragrant fibrous root of *Andropogon muricatus*, a swamp-grass occurring in India, where it is woven into screens for windows and doorways, and into palanquin covers. When sprinkled with water, an agreeable odour and coolness is diffused. The root has been used in medicine for a variety of purposes. In Europe the V. is laid in drawers as a perfume, and to keep away moths. It is remarkable for retaining its fragrance for many years. An oil extracted from it is used in perfumery.

Ve'to (Lat. 'I forbid'). In constitutional governments, the power of the executive to negative the resolutions of the legislature may be either absolute or negative. The *Liberum V.* of the kings of Poland (q. v.) was absolute, as also theoretically is the power vested in English sovereigns, last exercised by Anne in 1707. On the other hand, the V. of a king of Norway is merely suspensive, and presidents of the United States, though by the Constitution of 1849 they may return a bill to Congress with their objections, cannot prevent its becoming law if passed by two-thirds of the House of Representatives and Senate. See also TRIBUNES, and PATRONAGE, ECCLESIASTICAL.

Ve'tro di Tri'na, or **Lace Glass**, is a beautiful ornamental variety of glass made at Venice by enclosing small rods or threads of opaque glass within an object made of transparent glass so as to form a regular lattice pattern; and at each intersection an air bubble is shut in to give beauty and variety to the work.

Veuill'ot, Louis, a French journalist and author, was born in 1813 at Boynes in the department of Loiret. In 1838 a visit to Rome made him an ardent Roman Catholic. In 1843 he joined the staff of the *Univers Religieux*, and since 1848, as its editor-in-chief, he has continued to be the passionate representative of the Ultramontane party. The violence of his attacks on Napoleon's Italian policy led to the suppression of his journal in 1860, but it was restored in 1867. Apart from his editorial labours, V. is a voluminous author, and his *Mélanges Réligieux, &c.* (18 vols. Par. 1857-76), *Pélerinages de Suisse* (1839), *Les Parfums de Rome* (1861), and *Les Odeurs de Paris* (1866), are among his more popular works. Charbonnel edited a collection of his finest passages in 1868.

Vev'ey, a favourite resort of visitors from all nations, first introduced to the world by Rousseau in his *Nouvelle Héloise*, is situated on the N.E. shore of the Lake of Geneva, occupying along with its eastern suburb, *La Tour*, a narrow strip of level ground between the vine-clad mountains and the lake, and commanding a magnificent view of the whole range of mountains which enclose the lake and the Rhone valley, from the Dent de Jaman and Tour d'Ay to Mont Velau, the Dent du Midi, and the Cornettis de Bize. Though the second town in the Canton de Vaud, V. cannot boast of any more imposing buildings than hotels and pensions. The church of St. Martin (1498) contains the remains of the regicides Broughton and Ludlow. Pop. (1870) 7887.

Vi'aduct (Lat. *via*, 'a way,' and *duco*, 'I lead'), a structure with open spans of masonry, brickwork, iron, or timber carrying a road above the level of the surrounding country. An *aqueduct* is a similar structure, but designed to serve as a watercourse. Viaducts are frequently employed to carry lines of railway across deep or wide valleys, or over existing channels of communication where embankments would be impracticable or inexpedient. The London and Greenwich railway (3¾ miles) runs over a continuous series of upwards of 1000 brick arches, and the London and Blackwall V. railway is nearly of equal length, and cost £1,083,950. The Crumlin V. (1800 feet long) in S. Wales is an interesting example of the iron-girder principle. Of timber viaducts in England, that on the Newcastle and Tynemouth railway, consisting of five wooden arches (each about 114 feet span) supported by masonry piers, is noteworthy; while two in the United States—one (2900 feet long) on the Richmond and Petersburg railway, and another (2200 feet in 10 spans) across the Susquehannah, are remarkable truss structures.

Via'na do Castell'o, a town in the province of Entre Douro e Minho, Portugal, 40 miles N. of Oporto, at the mouth of the Lima, which is crossed by a large wooden bridge. It is a clean and prosperous town, with a fort built by Philip II., and a good harbour. There is trade with Newfoundland in fish. In 1875 17 ships of 2041 tons belonged to this port. Pop. (1864) 6049.

Viardot-Garcia, Madame Michelle-Pauline, an operatic singer, daughter of Manuel Garcia (q. v.) and younger sister of Madame Malibran (q. v.), was born in Paris, July 18, 1821. She was a pupil of Liszt. She appeared as Desdemona in London in 1839, and proving herself a worthy successor to her great sister, soon obtained a European reputation. In 1840 she married M. Louis V., director of the Italian Opera in Paris. Perhaps her greatest successes were in Meyerbeer's operas, *Les Huguenots* and *Le Prophète*, as Valentine in the former, and as Fides in the latter. Her splendid voice had a compass of 3 octaves, and she shone in the concert-room, particularly in the rendering of Spanish songs, as conspicuously as on the stage.

Viareggio, a town of the Riviera, province of Lucca, N. Italy, 91 miles E. of Genoa by rail. It is a new town, and has grown rapidly of late years, and is much resorted to for sea-bathing. Near it are ruins of old Roman baths—the *Bagni di Nerone*. Pop. (1871) 9371.

Viat'icum (Lat. 'provision for a journey') was a name anciently applied both to the sacraments of Baptism and the Eucharist, because they were esteemed men's necessary provision and proper armour, both to sustain and conduct them safe on their way in their passage through this world to eternal life. Afterwards, however, it came to be applied more particularly to the Eucharist when administered to the sick who were in imminent danger of death, as a provision for their journey to the next world.

Viat'ka, a government of Eastern Russia, bounded N. by Vologda, E. by Perm, S. by Ufa and Kasan, W. by Nijni-Novgorod and Kostroma. Area, 59,114 sq. miles; pop. (1870) 2,406,024. Much of the surface is covered with hills of no great height, offshoots from the middle Urals, which are separated from each other by swamps and sandy wastes. About 76 per cent. is covered with wood, mostly the property of the crown. All the rivers of V. belong to the basin of the Kama. The geological structure of P. is uniformly marl, slate, and limestone of Permian formation. The inhabitants are principally occupied with agriculture (chiefly in the S., where rye, oats, barley, flax, and hemp are cultivated with success), horse and cattle rearing, fishing, lime-burning, and the manufacture of potash, tar, pitch, bast, sledges, and wooden fabrics, mill-stones and grinding-stones. Mining and smelting are also actively carried on. In 1873 there were within V. 100 factories, employing 23,548 men, and producing goods (principally leather, brandy, and iron fabrics) to the value of 11,680,305 rubles. V. sends corn, hemp, and lint to Archangel, and iron, copper, tar, pitch, wax, honey, and timber to Moscow, and to Nijni-Novgorod, Orenburg, and the other governments of the Volga.—**V.**, capital and centre of the trade of the preceding, on the river V., 220 miles N. of Kasan, has 18 churches, a famous monastery (founded 1580, which formerly possessed 24,000 serfs), and 16 factories, in which leather and wax, stearine and tallow candles are manufactured. Pop. (1875) 21,249.

Viaud, Théophile de, born in 1590 at Clairac in Agenois, came to Paris in 1610, and by his talents and sprightly wit secured the patronage of the young lords and choicest spirits of the day. With Balzac he made a tour in Holland, next entered the household of the Duc de Montmorency, and, after writing court ballets and masques, had a great success with the tragedy, *Pyrame et Thisbé* (1617). His fondness for satire made him enemies, who, coupling obscenity with the charge of heresy, procured his banishment (1619); but after a two years' exile in England he returned to Paris, and abjuring Calvinism followed the king on his campaigns of 1621-22. Persecution, however, soon recommenced, his attack on a single Jesuit rousing the hatred of the entire order; and for the filthy *Parnasse Satirique* (1623), published under his name but without his knowledge, if indeed he had any part in it at all, he was sentenced, first to death (1625), then to perpetual banishment. Montmorency obtained him leave secretly to return to Paris, where at the age of thirty-six he died in the duke's hôtel, 25th September 1626. Odes, sonnets, epistles, and elegies, fresh but fantastic, make up with vigorous prose the bulk of V.'s works, which, unduly exalted in the 17th c., fell in the 18th into complete oblivion, from which they were rescued by the Romanticists. See the preface to Alleaume's edition of them (2 vols. Par. 1856), and Théophile Gautier's *Les Grotesques* (Par. 1844).

Viaz'ma, a town of Smolensk, Russia, on the river V., an affluent of the Dnieper, 172 miles N.W. of Tula by rail, with 25 churches, and an active trade with Riga and St. Petersburg in corn, leather, hemp, and oil. Its gingerbread is sent to all parts of Russia. Pop. (1875) 11,637.

Vi'borg, a län of Finland, comprising that part yielded to Russia by Sweden by the treaties of Nystad (1721) and Abo (1743), lying S. of Karelia between the Gulf of Finland and the Lake of Ladoga. Area 1662 sq. miles; pop. (1875) 289,010 (88 per cent. Lutheran). The surface is mostly mountainous, but is marshy along the coast. The principal rivers are the Voxen and the Kymene. The inhabitants are occupied with agriculture, cattle-rearing, fisheries, and a coast transit-trade.—**V.** (Fin. *Viipuri*), the chief town, is situated in a marshy and unhealthy district on Tragösund, a bay in the Gulf of Finland, 74½ miles N.W. of St. Petersburg by rail. Founded in 1213, it is the seat of the governor of V., of a Lutheran consistory, and of the high court for the three governments of Kuopio, St. Michael, and V., has 4 churches, an old Gothic castle, manufactures of stearine, and a considerable trade in timber. Pop. (1875) 13,460.

Vi'borg, chief town of an *amt* of the same name in the peninsula of Jutland, Denmark, on the small lake of V., 33¾ miles W. of Randers by rail. It is one of the oldest towns in Denmark. Its cathedral, which dates from the 12th c., was rebuilt after the fire of 25th and 26th January 1726, which laid half the

town in ashes. V. has manufactures of leather and tobacco. Pop. (1870) 6500.

Vibrac'ula, the name given to the peculiar moving or vibratile filaments associated with the 'Birds' Head Processes' or *Avicularia* of the *Polyzoa*. Their nature is still undetermined, but some authorities believe them to be rudimentary *polypides* or *Zooids* (q. v.).

Vibur'num is a large genus of *Caprifoliaceæ*, consisting of shrubs and trees found through temperate and sub-tropical regions of the N. hemisphere, and on the Andean range in S. America. Two species are natives of Britain, namely, the *V. opulus*, or the Guelder Rose (q. v.), and *V. lantana*, or wayfaring-tree. The latter is common in hedges and copses in S. England; and its hard white wood is useful in turnery. The leaves and berries are astringent and the bark acrid. In India the fruit of several species of V. is eaten, that of *V. cotinifolium* and *V. fœtens* being sweetish, and that of *V. stellulatum* of an acid flavour. In N. America the name cranberry-tree is given to *V. oxycoccus*—its fruit having an acid taste resembling that of cranberries, but the fruit of *V. edule*—also N. American—when fully ripe is preferable. *V. tinus* is the well-known Laurustinus (q. v.).

Vic'ar. See Parson.

Vice-Ad'miral. See Admiral.

Vice-Chan'cellor, a judge in the Chancery division of the High Court of Justice, acting as an auxiliary to the Lord Chancellor. There are three vice-chancellors in this sense, the first having been appointed in 1814, and the two others on the abolition of the equitable jurisdiction of the Court of Exchequer in 1841. They take precedence next after the Lord-Justices of the Court of Appeal. Each V.-C. holds a separate court, and his decisions are subject to appeal to the Lord Chancellor or to the Lord-Justices of Appeal. The judge of the local court of chancery of the duchy of Lancaster is also called a V.-C., the chancellor of the duchy having no judicial functions.

The V.-C. of a university is a dignitary acting for the chancellor in his absence in the granting of degrees, &c. Those of Oxford and Cambridge hold office for one year.

Vice-Cham'berlain. See Chamberlain, Lord.

Vice-Con'sul, an officer acting in a certain place as subordinate to the consul of the district. He is selected by that consul, and appointed by the Secretary of State for Foreign Affairs.

Vicen'za, an old city of N. Italy, in Venetia, at the base of the Monti Berici, on both sides of the Bacchiglione, 42 miles W. by N. of Venice by rail. Surrounded by a wall and moat, it is entered by eight gates, and contains at least one fine square, the Piazzi dei Signori, in which stands a fine, lofty campanile, and Gajassi's statue of Palladio (1859). The sinuous Bacchiglione is here crossed by seven bridges. The Palazzo della Ragione, or town-hall (begun 1549), with its grand double series of open arcades, is one of Palladio's earliest works; others by the same hand are the Palazzo Chieregati, now containing the rich Museo Civico, and restored after a fire in 1855; the large Corinthian Palazzo Prefettizio (1571), and the Teatro Olimpico, inaugurated with the Œdipus Tyrannus in 1584. The Duomo, a Gothic edifice, dates from 1467. The churches, of which there are in all twenty-five, are rich in works of art; S. Corona contains a 'Baptism of Christ' by G. Bellini, S. Stefano an altar-piece by Palma Vecchio. The sanctuary of the Madonna del Monte on Monte Berico is approached by an arcade of 168 arches, and is 715 yards long. V. is the seat of a bishop, and has a royal gymnasium and lyceum, an Episcopal gymnasium, a public library of 62,000 volumes, a Pinacoteca with works of Van Eyck, Titian, the Bellinis, &c., and various learned and benevolent institutions. There are some silk and cloth industries, and a trade in cattle, grain, and fruits. Pop. (1876) 37,277. V. is the *Vicentia* or *Vicetia* of the Romans, and was destroyed by Attila in 452. In the Middle Ages it was ruled by independent princes, but later it fell successively under the Scala and the Visconti, and was eventually made subject to Venice. It was the seat of an art school best represented by Montagna, and the chief sphere of Palladio, the last great architect of the Renaissance.

Vice'roy (Fr. *vice-roi*, from Lat. *vice*, 'in place of,' and *rex*, 'king'), the title of an officer representing the regal authority in a dependency, as the Lord-Lieutenant of Ireland, and (since 1858) the Governor-General of India. Under the old Spanish monarchy the title was officially given to the governors of Naples, Peru, Mexico, and other dependencies.

Vich, or **Vique**, a town of Spain, province of Gerona, 24½ miles N.E. of Barcelona by rail. Its cathedral (founded 1040 and restored 18th c.) has fine Gothic cloisters. Weaving and paper-making, the manufacture of hats, combs, knives, &c., and the mining of coal, copper, amethyst, and topaz are the chief industries. Corn and wine are produced in the district. Pop. 10,700. V., or *Vic-de-Osane*, is a corruption of *Vicus Ausoniensis*, this town having been the capital of the Ausetani. It was the seat of a Visigoth bishop, and was sacked by Arabs in 713. A battle between French and Spaniards took place here, 19th February 1810.

Vi'chy, one of the most fashionable watering-places in Europe, in central France, department of Allier, beautifully situated on the river Allier, amid orchards and vineyards, 35 miles S. of Moulins by rail. Lying at the base of the volcanic mountains of Auvergne, it is celebrated for its hot alkaline springs, and has handsome hotels, elegant baths, and beautiful gardens. The Établissement Thermal (1787–1821) is perhaps the largest edifice of the kind in Europe Adjoining it are the magnificent Casino, a theatre, assembly and reading rooms, &c. The waters are used for drinking as well as bathing, and are singularly efficacious for indigestion, gout, catarrh, &c. Pop. (1872) 6028. See Grellety, *V. et ses Eaux Minerales* (V. 1877).

Vicia. See Vetch and Bean.

Vicks'burg, the capital of Warren County, Mississippi, U.S., is situated on the Mississippi River, midway between New Orleans and Memphis, with both of which it has steamboat communication. Though the first city in the State, V. has no buildings of any note, and its commercial prosperity, which is considerable, depends almost wholly on the cotton plantations in its vicinity. Of its thirteen churches, six are exclusively for blacks. V. is known in Europe chiefly from the siege it endured during the Civil War from General Grant, which began June 28, 1862, and ended in the capitulation of the garrison July 4, 1863. In the summer of 1878 an epidemic of yellow fever carried off 566 lives. Pop. (1877) 12,443.

Vi'co, Giovann'i Battist'a, an Italian philosophical writer, was born at Naples, June 23, 1669. He early displayed unusual ability. At the close of his legal studies he obtained the post of tutor in the family of the Marchese della Ronca; and for nine years, in the delightful solitude of the castle of Patella, he lived the life of a studious recluse, imbuing his mind with ancient lore, and meditating much on theological, philosophical, and political problems. In 1697 he was appointed professor of rhetoric in the university of Naples, but his salary was so small that he had to eke it out by private tuition. It was not until 1734–35 that, as historiographer to Charles III., with a salary of 100 ducats, the greatest Italian philosopher of his time attained a sufficient competency. And the change came too late; V.'s health was impaired, and his spirit broken. Afflictions had fallen heavy on him. Several of his children had been taken from him by death; a daughter was stricken with an incurable disease, and a prodigal son had finished his life in prison. To crown all, the old man lost his memory, and had to retire from public life. He died January 21, 1743. V.'s *Principii di una Scienza Nuova d' intorno alle Commune Natura delle Nazione* (Naples, 1725), entitles him to rank as the founder, or at least the anticipator, of the modern philosophy of history. His 'Visions' on Homer were prelusive of the Wolfian theory, and his treatment of Roman history contained the essential elements of Niebuhr's criticism. Among his minor works are *De Rebus gestis Ant. Caraphæ libri quatuor* (Naples, 1716), and *De universi Juris uno Principio et Fine uno* (Naples, 1720), the latter a remarkable treatise. The *Nuova Scienza* has been frequently reprinted (Milan 1816, Naples 1826, &c.), and translated into German by Weber (Leip. 1822), and into French by Michelet (Par. 1827) and the *Princess Belgiojaso* (Par. 1857). A collected edition of V.'s works was published by Ferrari (6 vols. Mil. 1834–35), and the Neapolitan publisher Morreno has since issued *Opere Complete di V. Illustrate e Tradotte da Pomodoro rivedute dal Prof. G. De Stefano* (8 vols. 1858–69). See V.'s own Autobiography (prefixed to first ed. of *Scienza Nuova*,

and often reprinted), Tommaseo, *G. B. V., ed il suo Secolo* (Rome, 1873); Werner, *Ueber G. V. als Geschichtsphilosophen*, &c. (Vien. 1877.

Vic'tor, the name of several Italian rulers. See VITTORIO.

Victo'ria Alexandri'na, Queen of Great Britain and Ireland, and Empress of India, born at Kensington Palace 24th May 1819, is the only child of Edward, Duke of Kent, George III.'s fourth son, and of the Princess Luise Victorie of Sachsen-Koburg, the widow of the Prince of Leiningen, and sister to Leopold, King of the Belgians. Her father's death in 1820 left her the heiress to the English throne, but till her thirteenth year this fact was kept from her, and in her own late words she 'cried much on learning it,' and presently remarked —'There is much splendour, but there is more responsibility.' Brought up in strict retirement, the young Princess was indebted to the Duchess of Northumberland for the supervision of her general studies (in Latin, modern languages, music, drawing, and botany), for her political training to the Whig Lord Melbourne; and at her accession, on 20th June 1837, all the court offices were filled by members of the great Whig houses. Indeed, her spirited refusal (1839) to change the ladies of the bedchamber, prolonging as it did the existence of the Melbourne ministry, was the single instance of opposition to the popular will; her wise interpretation of the duties of a constitutional sovereign being that 'she should be, if possible, the best-informed person in her dominions as to the progress of political events and the current of political opinion both at home and abroad,' and that, so far from being either passively indifferent or warped by party considerations, she, 'as the nation's permanent head, has to consider what is best for its welfare and honour, without distinction of party.' She had known two years before Prince Albert (q. v.) himself of the marriage between them projected by King Leopold and Baron Stockmar, and, writing to her uncle in 1836, at the close of her cousin's first visit to England, had begged him 'to take care of one now so dear to her.' Dear to her then, but how much dearer during those happy twenty years of wedded life (February 10, 1840–December 14, 1861), in which five daughters and four sons were born, and whose visits of or to foreign kings and emperors sink into nothingness beside the Highland days, or the German tour of 1845 to her husband's boyish haunts. 'They say,' she wrote in 1844, 'no sovereign ever was more loved than I, and this because of our happy domestic home, and the good example it presents.' Sympathy now is added to love for one who, always sympathising with her subjects' sorrows, lost in 1861 both mother and husband, and in 1878 her second daughter, the Princess Alice. Her eldest daughter, the Princess Victoria (born 1840), had married in 1858 the Crown Prince Friedrich Wilhelm of Prussia, and to the period of the Queen's bereavement belong the marriages of the Princess Alice (born 1843) to Prince Ludwig of Hessen in 1862, of the Prince of Wales (q. v.) in 1863, of the Princess Helena (born 1846) to Prince Christian of Slesvig-Holstein in 1866, of the Princess Louise (born 1848) to the Marquis of Lorne, appointed (1878) Viceroy of Canada, in 1871, of the Duke of Edinburgh (born 1844) to the only daughter of the Emperor Alexander of Russia in 1874, and of the Duke of Connaught (born 1850) to the Princess Louise-Marguerite, third daughter of Prince Friedrich Karl of Prussia, in 1879. To that same period belong the terrible illness of the Prince of Wales (1871), and Her Majesty's visits to Switzerland (1868), Germany (1876), and Italy (1879). The first ten years of her widowhood were passed in close retirement, and though in 1871 the Queen was present at the opening of Parliament, her speech was read by the Chancellor; but grief has never for a moment interfered with her necessary duties as sovereign or with her interest in the nation's welfare. For her husband she has reared the stately Frogmore Mausoleum, and to her people has given those singular monuments of her joys and sorrow—*The Early Life of the Prince Consort* (1867), *Leaves from the Journal of our Life in the Highlands* (1869), and *The Life of the Prince Consort* (vols. i.–iv. 1875–79), the first compiled under Her Majesty's direction by the late General Grey, the last by Theodore Martin. The history of her reign down to 1876 has been sketched already under GREAT BRITAIN, and in the articles on the different premiers; and its subsequent chief events, the annexation of Cyprus in accordance with the Anglo-Turkish Convention, the War in Afghanistan, and the Zulu War, are respectively treated of under TURKEY, YAKOOB KHAN, and ZULUS. See also Nassau Molesworth's *History of England from the Year 1830* (3 vols. Lond. 1871–73), and Justin M'Carthy's *History of our own Times, from the Accession of Queen V. to the Berlin Congress* (vols. i.–ii. Lond. 1879).

Victo'ria, the smallest but most populous and most important of the five colonies into which the Australian continent is divided. It is included between 34°–39° S. lat., and 141°–150° E. long., and would much more accurately have been termed S. Australia than the colony which misleadingly bears that name. The extreme length of V. from E. to W. is 480 miles, and its extreme breadth from N. to S. about 250 miles. Its area is 88,198 sq. miles, which is a 34th part of the total area of Australia, and 1456 sq. miles less than the combined area of England, Wales, and Scotland, without their dependent islands. The coast line of V. is about 600 miles long, and is broken chiefly by the inlets of Port Phillip (q. v.) and Western Port, and the headlands of Cape Otway (q. v.) and Wilson's Promontory.

The greater portion of V. consists of open timbered country, on which the trees grow as in a park. In the N.W. and N. are extensive plains, usually devoid of trees, but in parts traversed by belts of scrub. They are devoted to sheep-runs, some of which are as large as an English county. In the W. there is a large area of country covered with mallee scrub (*Eucalyptus oleosa*), and in the S. and E. there are forests of magnificent trees. The colony is traversed throughout its length by a range of mountains forming part of the great Australian Cordillera (see AUSTRALIA), and bearing different names in different parts. This chain, which forms the watershed of the colony, is both widest and loftiest in the E. of V., where its leading ranges are known as the Bogong Mountains (q. v.) and Australian Alps. The former contain the highest peaks in the colony, culminating in Mount Bogong (6588 feet). There are also in V. four other mountains whose height exceeds 6000 feet, eleven between 5000 and 6000 feet, and 15 others more than 4000 feet high. Nevertheless the river system of V. is insignificant, the Murray (q. v.), which forms its northern boundary for 670 miles, being fed chiefly by rivers flowing through New South Wales. The largest river whose course is wholly in V. is the Goulburn (230 miles long), a tributary of the Murray. The Goulburn and the Yarra Yarra (length 90 miles), on which the city of Melbourne stands, are the only Victorian rivers navigable by craft larger than boats. The other principal streams are the Glenelg, Avoca, Loddon, Ovens, and Snowy. In dry seasons most of the Victorian rivers are reduced either to rivulets or to mere chains of ponds. Lakes, both salt and fresh, are numerous, but many of them are little more than swamps in times of drought. Some of them occupy the craters of extinct volcanoes. The largest lake in the colony is Lake Corangamite, which has an area of 76 sq. miles, has no outlet, and is salt.

The climate of V. is extremely salubrious, and more temperate than that of any other continental colony of Australia. At Melbourne, which fairly represents the average climate of the colony, the mean annual temperature is 57·6 deg., approximating to that of Marseilles or Nice. In the smallness of the yearly range of the thermometer, however, the climate of Melbourne more closely resembles that of Lisbon. Hoar-frost and ice occur sometimes in July, and less often in June and August. Thunderstorms are frequent and severe, but the hot winds, which blow from the interior for about fourteen days every summer, are the most trying feature of the climate. They blow with great violence, bringing with them dense clouds of dust, and during their continuance grass is withered up, fruit falls from the trees, and animals suffer greatly. The wind usually changes to the S. with great suddenness, and the temperature then falls from 20° to 30° in half an hour. At Melbourne, during the thirty-five years 1840–74 inclusive, the mean annual rainfall was 27·58 inches, and the mean annual number of days on which rain fell was 135.

The indigenous fauna of V. is the same as that of extra-tropical Australia generally, including kangaroos of different species, the wombat, Ornithorhyncus (q. v.), emu, and other characteristic Australian mammals and birds, as well as snakes, lizards, &c. On the whole, however, V. is less rich in animal life than New South Wales. Sheep, cattle, and horses thrive to perfection, and their numbers are now immense, while rabbits have multiplied so as to become a serious pest in some districts. Hares, deer of several kinds, Angora goats, pheasants, Cali-

fornian quail, and other birds, have been successfully acclimatised, and some of the streams have been stocked with brown trout, perch, and carp from England. Attempts have also been made to introduce the salmon, but hitherto without success.

The flora of V. includes many species of Eucalyptus (q. v.), some of which yield timber unsurpassed in size or quality by any in the world; and among the other characteristic trees of the colony are many kinds of wattle (*Acacia*, sp.), Banksia (q. v.), Casuarina (q. v.), and arborescent ferns. The climate favours the growth of all the fruit-trees of Central and Southern Europe, such as the vine, orange, lemon, fig, olive, and mulberry, but the first alone is as yet extensively cultivated. Tobacco of good quality is produced, and its culture is extending. The warmer localities are suited to the growth of cotton, but V. will never be able to compete with Queensland and the South Sea Islands in regard to this crop. When labour is cheaper, it is probable that attention will be given to the cultivation of tea, much of the colony being well suited to that plant. Wheat of fine quality is extensively grown, as well as oats and potatoes in the southern and upland districts. In 1877 the total area under tillage in V. was 1,231,105 acres, of which 401,417 acres were in wheat, 115,209 acres in oats, 333,751 acres in artificial grasses, and 40,450 acres in potatoes.

The mineral wealth of V. is very great, and to it the colony owes its marvellously rapid prosperity. Gold was discovered at Clunes in March 1850 by the Hon. W. Campbell, but he kept the matter secret for more than a year. On 5th July 1851 gold discoveries at Anderson's Creek in the Yarra Ranges, and in the portion of the Great Dividing Range known as the Pyrenees, were made public; and as further and richer discoveries speedily followed, a 'rush' set in from all parts of the world. Tens of thousands of men flocked to V. as fast as ships could be obtained to carry them, and towns and villages sprang into existence with amazing rapidity. In 1852 gold was obtained to the value of £8,875,128, and in 1856 the yield reached its maximum, viz., £11,943,964. Up to the end of 1878 the total value of the gold obtained in V. was £192,156,524. For a number of years past the amount of gold obtained from alluvial diggings has been steadily decreasing, and 'digging' in the original sense of the term has been giving place to the extraction of gold from quartz veins. Some of the mines from which the auriferous quartz is taken are of great size and depth, the greatest depth at which gold had been obtained up to September 1878 being 1988 feet. In 1877 the total value of the goldmining plant in use in the colony was £2,000,000; and in 1878 the total yield of gold in that year, from alluvial and quartz workings combined, was 755,754 oz., valued at £3,023,016, and obtained by about 36,600 miners. As compared with 1877, these figures show a decrease of 37,085 oz. of gold, valued at £148,340, and of 1400 miners, nearly all of whom had been employed in alluvial workings. For particulars regarding some of the principal nuggets found in Victoria, and which rank among the largest obtained anywhere, see the article NUGGET. V. contains other metals, &c., besides gold, though these resources are as yet but little developed. Tin is found in considerable quantity in the Beechworth (q. v.) district; iron is plentiful in many places, and is beginning to be wrought at Ballarat; copper is found in Gippsland; and lead, antimony, and manganese are also obtained in the colony. Unfortunately, coal is both scarce and poor, and for this important article V. is dependent on New South Wales, though it is reported that good coal exists in Gippsland in a district difficult of access. The colony is rich in building-stones and marble, and valuable slate-flagging is obtained near Castlemaine. Diamonds of small size, but fine quality, have been found, as well as good specimens of the ruby, sapphire, topaz (white, blue, and pink), beryl, garnet, and onyx.

The commerce of V. is very extensive, and is carried on chiefly with the neighbouring colonies, the United Kingdom, United States, and China. In 1877 the total value of the imports was £16,362,304, and of the exports £15,157,687. Of the latter, wool was much the most important item, after it coming gold, tallow, hides, skins, and preserved meats. A considerable proportion of the gold obtained in the colony is coined at the Melbourne mint. On June 30, 1878, there were 967 miles of railway open for traffic, the traffic receipts for the preceding twelve months amounting to £1,199,058; and in 1877 there were 2885 miles of telegraph in operation. The rateable property in municipalities at the same date was valued at £77,000,000; and the public revenue of the colony for the financial year 1877-78 was £4,723,877. The public debt on 30th June 1878 was £17,022,065, or £19, 12s. 4d. per head of the pop., which was officially estimated to be 867,634 on the same date. At the last census, taken in 1871, the pop. was 731,528, of whom 17,935 were Chinese, and 1330 aborigines; and on December 31, 1877, it was estimated to have risen to 800,803. The colony is divided into 37 counties, and its capital, Melbourne, is the most important city in the southern hemisphere. The other principal towns are Ballarat, Sandhurst, Castlemaine, Geelong, Williamstown, Daylesford, and Warrnambool, particulars regarding which will be found under their respective headings. An International Exhibition is to be opened 1st October 1880, and the building, which is to cost £95,000, is (1879) in process of construction.

V. was first seen by Lieutenant Hicks, an officer of Cook's expedition, who sighted the coast of Gippsland on 19th April 1770. In 1803 the first attempt at a settlement was made near the entrance to Port Phillip by a Government expedition from Sydney, headed by Colonel Collins, but it was speedily abandoned. In 1824 the explorers Hamilton Hume and W. H. Hovell reached Port Phillip overland from Sydney, discovering the river Murray on their way. In 1825 another abortive attempt at settlement was made, this time on the shores of Western Port. On 19th November 1834 the Messrs. Henty, merchants in Tasmania, founded the first permanent settlement in V. at Portland Bay. On 28th August 1835, an expedition organised by John Pascoe Fawkner, an innkeeper at Launceston, Tasmania, founded a settlement which afterwards became the city of Melbourne. In 1836 the interior of V. was explored by Sir Thomas Mitchell, whose glowing report led to a rapid influx of population from New South Wales, Tasmania, and the United Kingdom. The regular government of the settlement commenced with the arrival of the first resident magistrate, Captain Lonsdale, on 29th September 1836, and on 1st July 1851 the district of Port Phillip was separated from New South Wales and formed into the colony of V., its pop. being then about 80,000. Almost at the same time the gold discoveries began, as detailed above. On 23d November 1855, the constitution of the colony, under which it received the privilege of responsible government, was proclaimed, and is still in force, with certain modifications. The government is now administered by a governor appointed by the Crown and holding office for seven years, assisted by an executive council of ten members, who are responsible to a legislative council composed of 30 members, representing 6 electoral provinces, and a Legislative Assembly composed of 78 members, representing 49 electoral districts. See *The Colony of V.*, by W. Westgarth (Lond. 1864); *The Gold Fields and Mineral Districts of V.*, by R. Brough Smyth (Melbourne and Lond. 1869); *Official Record of V. for the Philadelphia Exhibition* (Melbourne 1875); *The Victorian Year Book*, by H. H. Hayter (Melbourne and Lond. 1878); Sabillière, *Early History of the Colony of V.* (2 vols. Lond. 1878); and R. B. Smith, *The Aborigines of V.* (Melb. and Lond. 1878).

Victo'ria, the capital of British Columbia, beautifully situated on the Strait of Fuca, at the S.E. extremity of Vancouver's Island. It is a free port with considerable trade, and in regular steamship communication with New Westminster, Olympia, and San Francisco, but owing to the shallowness of the harbour large vessels have to unload at Esquimalt, 3 miles distant, where also the British naval force is stationed. Besides handsome government buildings, V. has five churches, a theatre, hospital, &c., and is rapidly increasing in importance. Founded in 1843 as a trading port of the Hudson's Bay Company, it became the capital of the new colony of Vancouver Island in 1859, and of Columbia in 1866, when the discovery of gold attracted a crowd of diggers. Pop. (1871) 4540.

Victo'ria, the capital of the Brazilian province of Espirito Santo (q. v.), is situated 270 miles N.E. of Rio de Janeiro, on an island in a bay forming a fine harbour. It is fortified, and has a considerable coasting trade. Pop. 6000.

Victo'ria is the name given in honour of Queen Victoria to the most magnificent genus of the natural order *Nymphaceæ* (q. v.). There is only one species recognised by botanists, namely, *V. regia* or *V. regina*, a native of the Amazonian region of S. America, where it appears to have been first observed by

the unfortunate botanical traveller Hænke in 1801, to have been met with by the French naturalist D'Orbigny in 1827, but not made known to European horticulturists until after its discovery in British Guiana ten years later by Sir Robert Schomburgk. This noble water-lily has floating leaves of a bright green above, and a deep purple or violet on the lower surface, measuring as much as 7½ feet in diameter, with a uniformly turned-up margin of about 3 inches, thus resembling huge shallow trays. The flowers, which are proportionately as large —some measuring 14 in. in diameter—are of all shades from white to pink, and are delightfully fragrant. The fruit is globular, and thickly beset with formidable prickles. The seeds are edible. In 1846 perfect seeds in a condition fit for germination were received at Kew, but the plants died whilst young. In November 1849 the V. flowered for the first time away from its native streams and lakes at Chatsworth, under the care of Sir Joseph Paxton. It has since been introduced successfully in the E. and W. Indies and other tropical countries.

Victo'ria and Albert, Order of. See CROSS, VICTORIA.

Victo'ria Lake, more commonly called **Lake Alexandrina**, a shallow, brackish lagoon on the coast of S. Australia, measuring 30 miles by 27, through which the river Murray (q. v.) discharges into the sea. It has a narrow entrance, with a dangerous sandbar, which only small vessels can cross.

Victo'ria Nyan'za, the largest known lake in Africa, was discovered by Speke on 30th July 1858, and first circumnavigated by Stanley in eighty days in 1875. Its centre is at the intersection of the parallel of 1° S. lat. with the meridian of 33° E. long. The lake is roughly rhomboidal in shape, and has an area of about 26,500 sq. miles, or six-sevenths of that of Scotland, and is about 3800 feet above the sea-level. On the S., S.E., and N.E. its coast-line is indented by large gulfs, and its shores are fringed by many islands, the largest of these being Ukerewe in the S.E. and Sasse in the N.W., each of which is about 40 miles long. The shores of the lake are hilly and ridgy on the N. and W., rugged and mountainous on the S. and S.E., thence proceeding northwards they are first low and marshy, and then bold and precipitous. Of the many streams which empty into the lake the chief are the Shimiyu in the S.E., which is a mile wide at its mouth, and is probably the longest source stream of the Nile, and the Kagera, Kitangulé, or Alexandra Nile, which disembogues on the W. The lake discharges at its N. extremity by the Victoria Nile, which issues from it at the Ripon Falls, 12 feet high, discovered by Speke and Grant in July 1862.

Victor-Perrin, Claude, Duke of Belluno and Marshal of France, was born at La Marche in the Vosges, December 7, 1764, and having served as drummer (1782-89), rose, thanks to the Revolution and his own bravery in the siege of Toulon (1793), to be brigadier-general of the East-Pyrenean Army. He saw two Italian campaigns, commanded in La Vendée, and on the revolution of 18th Brumaire attached himself to the First Consul, following him once more to Italy, where at Marengo (1800) his eight hours' stubborn resistance turned the impending defeat into a victory. Ambassador to Denmark (1805), he was taken prisoner in the Prussian campaign, but exchanged for Blücher in time to earn at the battle of Friedland a marshal's baton (1807); and having held the governorship of Berlin, was despatched to the command of the 1st corps d'armée in Spain (1808), where his success at Espinosa and Medellin hardly made up for the defeats of Talavera and Barossa. In the retreat from Moscow he signalised himself by covering the passage of the Berezina (1812), at Dresden cut off the Austrian left wing (1813), and in 1814 fought with his wonted gallantry till a wound received at the battle of Craonne ended his military career. To Napoleon V. owed his advancement, but on Napoleon's fall he became a royalist, accepting a pension from Louis XVIII., and even presiding at his old colleague's trial. In 1821 he was minister of war, and two years later was appointed ambassador to the court of Vienna, which refused, however, to recognise his ducal title conferred by Napoleon; thenceforward he lived in strict retirement, dying at Paris, March 1, 1841.

Vi'docq, Eugene François, a French adventurer, was born at Arras, July 23, 1775. After a dissolute and wandering life, in which he had been sharper, soldier, forger, and convict, he served from 1808 till 1827 as a detective in the Paris police, and assisted materially in ridding the city of the dangerous classes whose ranks had been so remarkably recruited during the revolutionary period. On his discharge from the force he established a paper-mill at St. Maudé, near Paris, and in 1836 he opened a private office for the recovery of stolen property, which was very naturally closed by the police, whose monopoly it infringed. He afterwards lived for some time in Belgium and England, and it is said that his services were employed by the republican government of 1848. He died at Paris, May 1857. It is doubtful whether he was really the author of the *Mémoires de V.*, published under his name (Par. 1828, new ed. 1868; Eng. trans. Lond. 1847), and at any rate they cannot be accepted as trustworthy. The other works professedly from his pen are still more certainly pseudonymous.

Vielle', the old name for the hurdy-gurdy. It had usually five strings, and was tuned in various ways. It was a favourite and even fashionable instrument in France in the middle of the 18th c. It is still played by itinerant Savoyards in the streets of London and Paris.

Vienn'a (Ger. *Wien*, Lat. *Vindobōna*), the Austrian Kaiserstadt, lies in a plain at the foot of the Wiener Wald, in an angle formed by a southern branch (miscalled 'canal') of the Danube and its tiny tributary, the Wien. The Danube itself skirts the fast-spreading N.E. suburb, following for 8¾ miles the artificial channel whose construction (1869-75) has saved V. from the fate of Szegedin. 'Lines,' or external fortifications, 12 feet high, and pierced by fourteen gates, still part the suburbs from the ten wards of V. proper, but will soon be levelled, as in 1858 were the ramparts encircling the Innere Stadt. These with their *glacis* have now given place to noble boulevards, which, formed by nine 'Rings' and the Franz Joseph Quai, are 3 miles long and from 50 to 70 yards wide, are traversed by tramways, and with their avenues, gardens, and sumptuous modern architecture present the strongest contrast to the tortuous streets and narrow *places* of the ancient Stadt. In the heart of the latter rises the cruciform Stephansdom (1144; mainly rebuilt 1300-1562), with long-drawn choir and triple nave (together measuring 354 feet), traceried windows of richest glass, fretted roof upborne by eighteen sculptured pillars, the 12th c. Romanesque façade flanked by octagonal towers, and the airy, open-work spire, 453 feet high (rebuilt 1860-64). Close by, the gloomy palace of the Burg, now for five centuries the Hapsburgs' residence, presents its 'simple amalgamation of diverse constructions with no especial styles'—the splendid Rittersaal (1804), the Augustine church (1330-1783), with Canova's marble monument to the Archduchess Christine, the Imperial Library of 20,000 MSS. and 300,000 volumes (12,000 incunabula), the Treasury, and sundry rich art and science collections. Other buildings of the Stadt are the Capuchin church (1632), containing the imperial vault, the church of Maria Stiegen, with an heptagonal tower 187 feet high, the new Synagogue (1853-58), the church of the Non-United Greeks (1804-58), adorned with frescoes by Rahl and Thiersch, the old Rathhaus (13th c.-1842), the former University buildings (1755; since 1857 occupied by the Academy of Sciences), the disused Exchange in Renaissance style (1856-60), the palaces of the archbishop (1640) and numberless princes and nobles, the massive convents, hospitals, and six-storied *höfe*, with grand arched gateways and overhanging roofs, all huddled together, all speaking of the past. In all, V. has 3 Protestant, 4 Greek, and 56 Catholic churches, and of the last 36 stand beyond the Rings, among them the baroque Karlskirche (1716-37), with a lofty dome and two minaret-like columns; the Altlerchenfeldkirche (1848-61), richly adorned with frescoes; the Gothic Elizabethkirche (1866); and, finest of all, the Votivkirche (1856-79), which, built in the purest 13th c. Gothic at a cost of £375,000, vies for its endless adornment and western spires (325 feet high) with the Stephansdom itself, certainly with any ecclesiastical structure of the present century. On either hand of the Votivkirche may be seen all seven lamps of architecture blazing together in sumptuous piles, the mushroom growth of a brief speculative mania that gave V. 2069 new buildings during 1870-76. Here stand the palaces of *nouveaux riches*, whose riches have taken wings; there vast hotels, run up to receive the guests that never came in 1873, and since disposed of for anything they would fetch, one of the largest to become the Central Police Office. Within six years the members of the Stock Exchange increased from 1000 to 3200, so a new Bourse was built in Renaissance style at a cost of £500,000 (1869-76): M. Tissot counts up the suicides

already committed in its corridors. Mania and panic both are over, and all that V. now can do is admire and complete her work. A five-storied Gothic Rathhaus (1872-82), with a tower 351 feet high, covers 205,535 sq. feet, and will cost £850,000; to its right have been rising since 1874 University Buildings in Renaissance style, at a cost of £800,000 more; to its left, classic Houses of Parliament; and in front the new Court Theatre, an Italian Renaissance structure, seating 2000 persons, is to be finished by 1881, after an outlay of £500,000. Also upon or near the Rings, and all in the Renaissance style, are the Art and Natural History Museums (building since 1871), the Künstlerhaus (1865-68), the Academy of the Plastic Arts (1872-77), and the Art and Industrial Museum (1868-71), adorned with sgraffito friezes and thirty-six medallion portraits. Vienna's choicest art-treasures are stored in the Belvedere (1715-24), close to the Lines, and once the residence of Prince Eugen. Its galleries, fortunate in a fair representation of every school, are specially rich in Flemish, Venetian, and Lombard master-works. Holbein's 'Jane Seymour' and 'Dr. Chamber,' Van Dyck's half-length 'Charles I.,' Velasquez' priceless 'Family Picture,' Titian's 'Karl V.,' and Rubens' 'Maximilian I.;' these, with other hardly less famous paintings, are splendidly reproduced in *Die K. K. Gemälde Galerie in Wien: Radirungen von W. Unger, Text von C. v. Lützow* (Part VI. Vien. 1878). In the Lower Belvedere are collections of antiquities, armour, and curiosities; and fine private picture-galleries are contained in the Lichtenstein, Schonborn, Czernin, and Harrach Palaces. Of ten theatres, besides the already-mentioned Hofschauspielhaus, the chief are the French Renaissance Opera-House (1861-68), which, holding 3000 spectators, atones for a somewhat undignified façade by its magnificent internal fittings; the Theater an der Wien (1845), the Karlstheater (1847), the Wiener Stadtheater (1872), and the Komische Oper (1874). Music has also its Musikvereins-gebaüde (1867-70), with a library of 20,000 musical works; science is represented by a magnificent chemical laboratory (1871), the meteorological institute (1872), and the buildings of the Horticultural Society; and to education are devoted the hitherto scattered buildings of the University (q. v.), a Polytechnic (1815) attended by 1509 students in 1876, seven gymnasia, ten *real-schulen*, and 176 elementary schools. The cost to the Commune of education was £257,142 in 1877, while close on £400,000 was spent on school buildings during the six preceding years. V. possesses more than 100 bridges (31 within the Lines), but two only are older than 1824. Worthy of special notice are the five constructed (1870-76) across the new channel of the Danube; the 14th c. Stubenbrücke, Tegetthoffbrücke (1872), and Elizabethbrücke (1854), adorned with eight marble statues, across the Wien; and across the Danube Canal the suspension Aspernbrucke (1864). This leads to the Prater, a Rotten Row and Greenwich Park combined, with its stretches of shady turf, its quadruple chestnut avenue, its streets of booths, and towering aloft the vast Rotunda, 344 feet in diameter, of the Weltausstellung of 1873, which was visited by 7,254,687 persons, but showed a heavy deficit in its receipts. In the Prater may be seen Vienna's favourite outdoor life, or in the Volksgarten (where Strauss's band plays daily), the Hofgarten, Stadtpark, and other pleasant gardens of the town itself, which like the *places* are adorned with numerous monuments and fountains—the Mariensäule (1667), Votivdenkmal (1732), equestrian statues of the Archduke Karl (1860), Prince Eugen (1865), and Fürst Schwarzenberg (1867), memorials to Schubert (1872), Schiller (1876), Zelinka (1877), &c. Of barracks, more numerous than well arranged, the chief is the Rudolfskaserne (1865-69); but V.'s great military establishment is the Arsenal (1849-55), standing beyond the Lines, near the Belvedere. Its spacious quadrangle, 520 by 440 yards, contains a hospital, church, barracks, and a fine museum of weapons, besides iron-works, a cannon-foundry, &c. New waterworks, the largest in the world, were constructed in 1870-74 at a cost of £2,400,000, and by means of tunnels and aqueducts bring water from the Alps, 54 miles distant. To enumerate the industries of V. were an impossible task, their value amounting in 1870 to £33,600,000; but among specialties are its manufactures of meerschaum, leather knick-knacks, carved furniture, jewellery, and terra-cotta, besides the brewing of its famous beer. Its situation also on a great water-highway, and as the centre of ten lines of railway, makes it a place of enormous traffic, in cereals, wine (231,000 hectol. 1876), minerals, stock (933,460 head), leather, wool, silk, and such like wares. From 175,460 in 1754, the population had grown in 1875 to 673,865, or with the suburbs 1,020,770; and of the 607,514 inhabitants in 1869, 545,506 were Catholics, 40,230 Jews, and 16,767 Lutherans. Only 270,911 were natives, the rest being Magyars, Czechs, Tyrolese, Poles, Greeks, Armenians, &c., whose Babel of tongues and national costumes distinguish V. from the great Western capitals.—Under the shadow of the Stephansdom stands the 'Stock im Eisen,' a pine-tree stump, clasped by an iron ring, and pierced with the nails of hundreds of journeymen locksmiths. Round the holy grove, of which it is last survivor, a Celtic settlement sprang up before the Romans in the 1st c. A.D. founded *Vindebona*, where Marcus Aurelius died (150), and which was a flourishing municipal town down to its destruction by Attila in the 5th c. Restored in the 12th by Heinrich Jasimirgott, who here fixed his residence as Duke of Austria and founded both Dom and Burg, V. increased so fast, thanks to its situation on the Crusaders' route, that under Ottokar of Bohemia (1251-86) the Stadt attained its present dimensions. From him it was wrested by Rudolf of Hapsburg (q. v.), and since has shared the fortunes of that dynasty. Besieged by the Turks under Suleiman II. (1529), and under Kara Mustapha (1683), it was saved on the first occasion by the valiant defence of Nikolaus von Salm, on the second by the appearance of John Sobieski; but in 1809 it had to capitulate after bombardment to the French. Its famous Congress (1814-15) resulted in the fifth Treaty of V., by which Austria recovered her cessions of 1809, Great Britain Hannover, and Switzerland her ancient constitution; the Pope was reinstated, Germany and Italy were re-distributed, Poland was united to Russia, Belgium to Holland, and Norway to Sweden. The October Revolution of 1848 placed the city for a time in the hands of the insurgents; in 1866 might be seen from its towers the watchfires of the Prussian victors of Sadowa. See Waagen, *Die Vornehmsten Kunstdenkmäler in Wien* (2 vols. Vien. 1866-67); Perger, *Der Dom zu St. Stephan* (Triest 1854); Weiss, *Geschichte der Stadt Wien* (Vien. 1872), *Topographie der Stadt Wien* (Vien. 1876), and *Führer durch Wien* (Vien. 1878); H. Reeve, *Journal of a Residence at V. in the Eventful Winter* 1805-6 (Lond. 1877); Tissot, *Vienne et la Vie Viennoise* (Par. 1878), and Felder, *Die Verwaltung der Stadt Wien in den Jahren* 1874-76 (Vien. 1878); Seis, *Wien und Umgebung* (4th ed. Vien. 1878); and the Earl of Westmoreland, *Great European Congresses of V.* (Lond. 1859).

Vienne, a department in the W. of France, comprises the E. part of the old province of Poitou. It is bounded W. by Deux Sevres, N. by Indre et Loire, E. by Indre and Haute V., and S. by Charente. Area, 2690 sq. miles; pop. (1876) 330,916. Its surface is mostly level, with some small hills in the S.; the centre is a rich plateau intersected by small valleys on the E. The chief river is the V., a tributary of the Loire, flowing N. through the department. The department contains mineral springs, iron mines, and quarries of lithographic stones, but the chief sources of revenue are wheat, oats, and wine, of which in 1876 there were produced respectively 4,600,750 bushels, 3,286,250 bushels, and 10,098,000 gallons. The capital is Poitiers (q. v.).

Vienne, a town of France, department of Isère, on the left bank of the Rhone, and a station on the Lyon-Marseille railway, about 19 miles S. of the former city. Besides the cathedral of St. Maurice (reckoned the finest specimen of Gothic architecture in France), and the newly-restored church of St. Pierre, V. contains a library, theatre, communal college, and museum of antiquities. The chief manufactures are of cloth and other woollen stuffs, in which 4000 workmen were employed in 1877, but paper, leather, silk, glass, machinery, and hardware goods are also made. Pop. (1876) of the commune, 26,502. From the time of the Romans, of whom the obelisk known as L'Aiguille, and the remains of a portico and amphitheatre are still extant memorials, V. has been a place of considerable importance. During the Middle Ages it was a Burgundian capital, and more than one Church council was held here, the most important being that of 1312, in which Clement V. pronounced the suppression of the Knights Templars.

Vienne, Haute-, a department of France S.E. of the department of V., is mostly hilly, and though rich in metals and various kinds of clay, is not well suited for agriculture. Chestnuts and vines, however, are cultivated to a considerable extent, and the upper meadows are grazed by a valuable breed

of horses. It is watered by the Upper V. and the Gartempe. The chief manufacture is porcelain, but there are also several spinning-mills, tanneries, paperworks, &c. Area, 2129 sq. miles; pop. (1876) 336,061. The chief town is Limoges (q. v.).

Vier'sen, a town of Rhenish Prussia, on the Nord-Canal, 5½ miles N.E. of Gladbach by rail. It has one Evangelical and one Catholic church, carries on dyeing and bleaching, and manufactures silks, half-silks, cottons, woollens, velvet, ribbons, lace, damask, leather, strawplait, and tobacco. Flax is extensively cultivated in the neighbourhood. Pop. (1840) 4543; (1875) 19,705.

Vierzon-ville, a town of France, department of Cher, at the confluence of the Yèvre and the Cher, 50¾ miles S. of Orleans by rail. It has some important ruins. There are manufactures of porcelain, glass, parchment, leather, hosiery, and vinegar. Corn and vines are grown in abundance. Pop. (1876) 8995.—**V.-Village**, less than a mile distant, has manufactures of lace and wire-drawing. Its once famous steel-works and blast-furnaces are no longer in operation. Pop. (1876) 1058.

Vie'ta, Franciscus, or **François Viette**, the greatest French mathematician of the 16th c., was born at Fontenai-le-Comte, near La Rochelle in 1540. He seems to have been entirely self-taught as a mathematician; but, excepting a few anecdotes related by De Thou, we know little of his life. He was *maître des requestes* at Paris under Henri III. and Henri IV., and did valuable service to his government in the decipherment of the secret communications of the Spanish court. The reformed Gregorian calendar of 1582 was attacked by V., who published what he deemed a more correct one in 1600, supplementing this publication by a vehement expostulation two years later. His death at Paris in 1603 probably prevented any action being taken against him similar to what Galileo experienced some years later. V. was the first to employ letters in algebra to signify quantities, and first systematically combined these with symbols of operation, thus greatly facilitating the application of algebraic methods to the working of problems. Besides thus being the founder of modern algebra, he greatly developed the theory of equations, and by means of his improved methods widely extended trigonometry, discovering the relations of multiple angles, and completing the solution of right-angled spherical triangles. He also gave an expression for the approximate quadrature of the circle. His works were collected and published by Schooten in 1646; but this edition does not contain the *Harmonicon Celeste*, of which two MSS. exist in Florence and Paris, and the *Canon Mathematicus* (1579), which contains the first complete table of the circular functions.

Vigan, Le, a town of France, department of Gard, 45 miles W. by N. of Nîmes. It has a corn-exchange built on the site of a Roman temple, and an avenue of splendid chestnuts. Near it are the mineral waters of Cauvalat. V. has manufactures of leather, silk, cotton, and wine, and horses are largely bred in the district. Pop. (1872) 4340.

Vige'vano, a town of Italy, province of Pavia, on the Ticino, 15 miles N.W. of Novara by rail. It has a large market-place surrounded by arcades, a fine cathedral, and the castle of Sforza (now a cavalry barrack). V. manufactures silk, macaroni, cotton, soap, and hats, and exports macaroni and silkworms. Pop. (1874) 14,096.

Vi'gil (Lat. *vigilia*, from *vigilare*, 'to watch') is the evening or night before a day sacred to some saint, which in the ancient church was spent, like those before the Lord's day and other great festivals, in praise and prayer till the morning light, generally in church, especially in churches dedicated to the saint whose festival was being commemorated. The popular English name is *Eve*—as Christmas Eve, Hallowe'en—and *Wake*, which is a literal translation of V. The observance of V. is still kept up in the Roman Catholic, and to some extent in the Anglican, Church.

Vignette' (Fr. *vigne*, 'a vine'), an engraving, not enclosed within a definite border, used for the embellishment or illustration of a book. The capital letters with tendril ornaments of ancient MSS., and, later, the head- and tail-pieces of printed books, were termed vignettes. The term is also applied to a running ornament of leaves and tendrils used in Gothic architecture.

Vigny, Alfred Victor, Comte de, a celebrated French poet, was born at Loches, Indre-et-Loire, 27th March 1797, of a noble family, which, strange to say, did not emigrate at the Revolution. He was educated at Paris, and admitted at the Restoration into the King's bodyguard of 'Gensdarmes de la Maison Rouge.' On the dissolution of this corps after the Hundred Days he entered the Royal Guard. While on frontier service at Pau during the Spanish War, in which, however, he did not take part, he met a young and wealthy English lady, Miss Lydia Bunbury, whom he married, and shortly after left the army (1827). As early as 1822 he had published his first collection of *Poèmes*, which was followed in 1824 by the graceful and touching allegory of *Eloa, ou la Sœur des Anges*. He was now recognised as one of the chief of the new Romantic school of poets, and gradually came more and more under the influence—for him by no means a beneficent one—of Victor Hugo, the leader of the school, whose influence was marked in the *Poèmes Antiques et Modernes* (Par. 1826; 2d series 1837), and became still more prominent in *Stello* (Par. 1832), in which V. related the tragic stories of the three poets, Gilbert, André Chénier, and Chatterton. His famous and highly successful, though now little read, historical romance, *Cinq-Mars, ou une Conjuration sous Louis XIII.*, had appeared in 1826, and from it Lord Lytton probably gained some ideas for his drama of *Richelieu*. It was in his drama of *Chatterton*, however, produced at the Théâtre Français, 12th February 1835, that V. achieved his crowning success, his previous dramatic attempts, in the shape of adaptations of *Othello* and the *Merchant of Venice*, and a historical drama, *La Maréchale d'Ancre*, having been little better than failures. In the same year he published his *Servitude et Grandeur Militaire*, the matter of which was drawn from his military experiences, and after this he lived in retirement and wrote little. In 1841 he addressed to the Chamber of Deputies a *Mémoire sur la Propriété Litteraire*, recommending that the heirs of an author should have an interest in every edition of his works. In 1845 he succeeded to the fauteuil of Etienne in the Academy, but was coldly received on his inauguration. He died at Paris, 17th September 1863, leaving a collection of poems published under the title of *Destinées* (Par. 1864), besides the *Journal d'un Poète* (1867), and the romances *La Veillée de Vincennes* (1867) and *Laurette ou le Cachet Rouge* (1867). See Mirecourt's *A. de V.* (Par. 1855), Porry's *A. de V., Étude Morale Litteraire* (Marseilles 1864), A. France's *A. de V.* (Par. 1868), Magnin's *Causeries Litteraires*, and Sainte-Beuve's *Portraits Contemporains*.

Vi'go ('Bay town'), a fortified seaport of Spain, province of Galicia, rising like an amphitheatre from the S. shore of the Ria de V., which runs up from the Atlantic Ocean for 20 miles between steep hills, 23 miles N.N.W. of Tuy by rail. It is surrounded by walls, and defended by two strong forts on the hill commanding the town. Its safe and commodious harbour is sheltered by an island within the bay. V. has productive sardine and tunny fisheries. In 1873 its imports amounted to £873,280; its exports (chiefly live stock, maize, hams, and sardines) to £381,640. It is a station for the English steam-packets between London, Southampton, and Oporto, Lisbon, Cadiz, and Gibraltar. Pop. 6800. In V. Bay the English and Dutch fleets under Rooke annihilated the Spanish 'Plate Fleet,' 23d October 1702.

Vik'ings (Old Norse *Vikingr*, 'creekers,' from their anchoring in *viks* or 'bays'), the Scandinavian pirates who from the beginning of the 9th c. ravaged the coasts of western Europe. See NORTHMEN, and the works there mentioned; also Dr. G. Storm, *Kritiske Bidrag til Vikingetidens Historie* (Christiania 1879).

Vik'ramadit'ya, a great legendary Hindu monarch of India, whose capital was at Oojein (q. v.) in Malwa, and whose era, 57 B.C., is still current in Hindustan proper. He is regarded as the champion of the revived Brahminic faith, who drove away the Buddhists to Ceylon.

Vilkomir', a town of Russia, government of Kovno, on the Sventa, 45 miles N.N.W. of Vilna. It has a fine old Catholic church, a synagogue, and a considerable trade in linseed. Pop. (1875) 11,118.

Villafran'ca, a town of Italy, province of Verona, on the Verona and Mantua Railway, has some considerable silk manufactures, but is chiefly celebrated as having been the main seat of the wars of 1848 and 1866. On July 11, 1859, the preliminaries for peace were signed here between the Emperor of Austria and Napoleon III. Pop. (1874) 8344.

Villafran'ca del Panades, a town of Spain, province of Barcelona, said to have been founded by Hamilcar, is the centre of some small inland trade in fruit and wine. It has a venerable Gothic palace of the Aragonese kings. Pop. 5500.

Vill'a Ri'ca, another name of Ouro Preto (q. v.), the capital of the Brazilian province of Minas Geraes.

Villa'ri, Pasqua'le, born at Naples in 1827, for participation in the Revolution of 1848 was forced to take refuge in Florence. Thence he was called (1859) to the chair of philosophy at Pisa, and thither, having meanwhile travelled in England and Germany to study their educational systems, he returned in 1866 to become professor of history in the Instituto di Studj Superiori. Among his works are *La Storia di Savonarola e de' suoi Tempi* (2 vols. 1859-61; Eng. trans. 1863); *La Civiltà Latina e Germanica* (1862); *Le Leggende che illustrano la Divina Commedia* (1865); *Macchiavelli* (1877; Eng. trans. 1878), and *Le Lettere Meridionali, ed Altri Scritti sulla Questione Sociale in Italia* (1878).

Vill'ars, Claude Louis Hector, Duc de, a French marshal, was born 8th May 1653 at Moulins. He began life as a page of the Grand Monarch, and his earlier campaigns were in the Netherlands and Hungary. In his later career the principal points are his victory at Pforzheim (1693), an embassy to Vienna (1697), the victories of Friedlingen (1702) and Hochstädt (1703), the suppression of the rebellion in the Cevennes (1704), his defeat at Malplaquet (1709), his victory at Denain (1712), and the campaign in Germany which was closed by the treaty of Rastatt. After a long period of peace, during which he became minister of state, he received the chief command in the Italian campaign of 1733. He died on the way to Turin, 17th June 1734, after the capture of Pizzighettone. V. was received a member of the French Academy in 1714. His *Mémoires* (the Hague 1734, 1758) are, with the possible exception of the first volume, the work mainly of the Abbé La Pause de Margon. See Anquetil, *Vie du Maréchal de V.* (4 vols. Par. 1784), and D'Alembert, *Hist. des Membres de l'Académie Française.*

Villar'sia, a genus of perennial water herbs belonging to the natural order *Gentianaceæ*, of wide distribution through temperate and tropical regions of the Old and New Worlds. The leaves are entire or lobed, and the flowers, which are usually yellow, are fringed with fine hairlike processes. In India *V. Indica* is used medicinally, and is a remedy for snake-bites.

Ville'franche de Rouergue, a town of France, department of Aveyron, on the river Aveyron, 76½ miles N.E. of Toulouse by rail. It stands in a mountainous district, and possesses many fine specimens of Gothic and Renaissance architecture. The Gothic church of Notre Dame, that of the Augustins, and a cloister of the Chartreuse monks, are the most interesting buildings. V. has manufactures of cloth, hats, and paper. The surrounding hills contain ores of copper, silver, and tin, and copper is extensively worked. Wine, corn, and copper utensils are exported. Pop. (1876) 7819.

Ville'franche-sur-Saône, a town of France, department of Rhône, on the Morgon, near its confluence with the Saône, 18 miles N. of Lyon by rail. It is well built, and contains an interesting Hôtel-de-Ville, and the church of Nôtre-Dame-des-Marais, dating from the 14th c. There is a library, a chamber of agriculture, and a Jesuit college. Cotton and woollen goods are manufactured, and there is a trade in horses, cattle, hides, cloth, hemp, and wines. Pop. (1876) 11,994.

Villehar'douin, Geoffroi Sire de, an old French warrior and chronicler, was born probably about 1155 or 1160, in the family château near Bar-sur-Aube. In 1180 he succeeded his father Guillaume as Marshal of Champagne under Thibaut, brother of Henri II. of France, and in 1201 he was one of the ambassadors despatched to Venice to make arrangements for the transport of the forces for the fourth crusade. On his return he found Thibaut dangerously ill, and it was soon his duty to act as guardian of the rights of the widowed princess, Blanche of Navarre. Having concluded a treaty in her name with the king, Philippe Auguste, he departed for the East, where he distinguished himself greatly in the conflict which finally placed Baldwin of Flanders on the throne of the Byzantine empire. Rewarded by the new monarch with extensive lands on the Hebrus, and appointed Marshal of Rumania, he repaid the favour by saving the crusaders from disastrous defeat near Adrianople in 1205. On his death in 1213 his nephew Geoffroi inherited his title and possessions. The narrative of the fourth crusade, by which V. ranks among the most important historians of the time, covers the period from 1198-1207, and consists largely of his own personal experience. Its principal defect is the prominence given to purely military matters. First published by Blaise de Viginère as *Histoire de la Conqueste de Constantinople, par les barons François associez aux Venetiens, l'ann 1204, d'un coste en son viel Langue et de l'autre en un plus moderne et intelligible* (Par. 1584), it has been frequently re-edited—by Ducange (1657); by Petitot in his *Collection des Mémoires*, tome i. (1819); by Bouquet in his *Rerum Gallic. Scriptores*, vol. xviii.; by Paulin Paris (Par. 1838); and by Natalis de Wailly (first edit. 1871, 2d 1874). There is an English translation by T. Smith, *Chronicles concerning the Conquest of Constantinople* (Lond. 1829), and a German translation by Todt (Halle 1878). See *Hist. Litt. de la France*, vol. xvii., and Marius Sepet, *Geoffroi de V.* (Par. 1874).

Villein. See SLAVERY.

Ville'main, Abel François, a celebrated French author, born at Paris June 11, 1790. Educated at the Lycée Louis-le-Grand, he was at the age of twenty appointed assistant-professor of rhetoric at the Lycée Charlemagne, and soon afterwards professor at the École Normale. In 1812 he gained the prize of the Academy for his *Éloge de Montaigne*, on the 21st April 1814 he read before the King of Prussia, the Czar Alexander, and the *élite* of Parisian society his essay *Avantages et Inconvénients de la Critique;* and two years after, he was crowned a third time for his *Éloge de Montesquieu* (25th August 1816). Already assistant to Guizot in the chair of modern history, V. was now appointed professor of French eloquence at the Sorbonne, and in a brilliant career of ten years carried the philosophic spirit that distinguished Cousin in philosophy and Guizot in civil history into the history of French literature. Before the publication of his lectures of 1827-30 as *Cours de la Littérature Française* (1828; new ed. 6 vols. 1864), he had won a high reputation as a critic by his *Mélanges* (1823; new ed. 1860) and *Nouveaux Mélanges* (1827), and as a historian by his *Histoire de Cromwell* (2 vols. (1819), and the dramatic study *Lascaris, ou les Grecs du XV. Siècle* (1825). Deputy for Evreux from July 1829, he was made a peer of France in 1832, and from 13th March 1839 to March 1, 1840 was Minister of Public Instruction. Reappointed on the 20th October, he was the leading promoter of the banishment of the Jesuits in 1844. About the end of that year ill-health forced him to forbear all mental labour, but in 1847 he had wholly recovered. After the establishment of the Empire, V. resigned all his appointments save his place in the Academy, to which he had been elected in 1821. The fruits of his leisure were *Études de Littérature Ancienne et Étrangère* (1846, 3d ed. 1865), *Tableau de l'Éloquence Chrétienne au IV. Siècle* (1846, new ed. 1870), *Souvenirs Contemporains d'Histoire et de Littérature* (1853, 2 vols. 1864), *Choix d'Études sur la Littérature Contemporaine* (1857), *Chateaubriand* (1857), *Essais sur la Génie de Pindare et la Poésie Lyrique* (1859), and *Histoire de Grégoire VII.* (2 vols. 1873). He died May 8, 1870. 'The French,' said Goethe, 'will never again see another genius like Voltaire; but V. is so superior to Voltaire in his point of view, that he can judge him in his merits and in his faults.' See Mager, *Geschichte der Französischen National-Litteratur neuerer und neuester Zeit*, vol. ii.

Villemar'qué, Théodore Claude Henri Hersart, Vicomte de la, was born at Quimperté, in Bretagne, July 6, 1815, and having early distinguished himself by his works on the Breton language and literature, received the decoration of the Légion d'Honneur (1846), and was admitted a correspondent of the Berlin Academy (1851), and a member of the French Academy (1858). Besides the works cited under BRETAGNE, V. has pub-

lished *Contes Populaires des Anciens Bretons* (2 vols. 1842), *Poëmes des Bardes Bretons du Sixième Siècle* (1850), *Notices des Principaux Manuscrits des Anciens Bretons* (1856), *La Légende Celtique en Irlande, en Camluè et en Bretagne* (1859), *Myrdhinn ou l'Enchanteur Merlin* (1860), *Le Grand Mystère de Jésus* (1865), &c.

Ville'na, a town of Spain, province of Alicante, 36¾ miles N.W. of the city of Alicante by rail. It has a town-hall, a palace, an hospital, and barracks. There are large brandy distilleries, and vines are cultivated extensively. A great fair is held every autumn. There is a large salt lake in the neighbourhood. Pop. (1876) 6600.

Ville'neuve, Pierre Charles Jean Baptiste Sylvestre De, a French admiral, born at Valensoles, Basses-Alpes, December 31, 1763, entered the navy in 1777, became captain in 1793, and captain-of-division in 1796. With this rank he commanded the rear division at the battle of the Nile, and succeeded in escaping to Malta with his own and four other vessels. In 1804 he became vice-admiral, and in 1805 was appointed to the command of the Toulon squadron, and ordered by Napoleon to divert the British fleet from the coasts of Europe in order to leave the Channel open for the invasion of England. With this view he sailed to the West Indies, and after cruising for a month recrossed the Atlantic, closely pursued by Nelson. At the Azores he fell in with a British squadron under Sir Robert Calder, which he fought till dark, and in the following morning bore away towards Brest, but was obliged to alter his course and sail to Cadiz, where he was blockaded by Nelson. The indignation of the Emperor, and the certainty of his being superseded, drove V. to risk an engagement with the blockading fleet, in the hope of repairing everything by a brilliant victory. Accordingly he sailed out of Cadiz and offered the enemy battle at Cape Trafalgar (q. v.). V.'s flag-ship, the *Bucentaure*, was captured, and the admiral carried as a prisoner to England. In the April of 1806 he was allowed to return to France, but learning that his reception by the Emperor would be unfavourable, he committed suicide at Rennes, April 22, 1806.

Ville'neuve-sur-Lot or **D'Agen**, a town of France, department of Lot-et-Garonne, on both sides of the Lot, 16 miles N.N.E. of Agen by rail. The part of the town N. of the river is connected with the Faubourg St. Etienne by the Pont-Neuf, a magnificent bridge of one arch with a span of 118 feet, and a height of 59 feet. V. has manufactures of linens, leather, boots and shoes, horn-combs, and pottery, and a considerable trade in corn, wine, and plums. Pop. (1876) 14,448.

Vill'i, the name given to those projections of the mucous membrane of the intestines which constitute the openings of the *lacteals* or *absorbent vessels*. The *chyle* or product of Digestion (q. v.) passes through the V., and is thence conveyed to the blood-system. The V. attain a length varying from a line to a line and a quarter, and may number from 50 to 90 per square line. The surface is coated with columnar epithelium, and internally are found blood-vessels and lacteal vessels.

Vill'on, François, one of the earliest French poets, was born at Paris in 1431. The few authentic details of his life which we possess are to be gathered from his verses, where he paints his own character in anything but favourable colours. His father was of humble rank, perhaps a shoemaker, and his mother appears to have been a woman of fine character, full of piety and love for her son. He began to attend the University of Paris, but soon deserted the lectures for evil courses of all descriptions, of which he makes full confession in many of his poems, and of which the *Repues Franches*, though admittedly not by V. himself, give a too faithful picture. He was in fact the first of the long series of literary Bohemians of Paris, always living at other people's expense, and very often carrying his love for the goods of others, or his boisterous debauches, to such a length as to land him in prison. Some exploit of this sort led to his removing in 1456 from Paris to Angers, and before leaving Paris he composed a burlesque will in verse, known as his *Petit Testament*. Next year, however, he was again in Paris, where he was shortly afterwards imprisoned in the Châtelet, and would probably have been executed but for the intervention of Charles d'Orleans. Again in 1461 we find him in prison, this time at Meury-sur-Loir, and after his release he seems to have composed his *Grand Testament*. After this his life is almost a blank. He is stated on the authority of Rabelais to have retired towards the end of his life to Saint-Maixent in Poitou, and also to have visited England. He died about 1487. His popularity may be judged from the fact that between 1489 and 1542 twenty-six editions of his poems were published in Paris and three in Lyon. The best modern editions are that in the *Bibliothèque Elzevirienne* (Par. 1854), that of M. Jannet (Par. 1867), and that of Paul Lacroix (Par. 1877). Several English translations have been made of his famous ballad, *Mais où sont les neiges d'Antan;* by Rosetti, among others. Swinburne has given us a version of the *Ballad of the Fair Armourer*, and an English translation of almost all his works has been privately printed by John Payne (Lond. 1878). See Besant's *Early French Poetry* (Lond. 1868), Campaux's *F. V., sa Vie et ses Œuvres* (Par. 1859), Nagel's *F. V.* (Berl. 1877), and Longnon's *Études biographiques sur F. V.* (Par. 1877).

Vil'na, a government of West or White Russia, surrounded by the governments of Kovno, Vitebsk, Minsk, Grodno, and Suvalki. Area 16,411 sq. miles; pop. (1870) 1,001,009. The surface forms an undulating sandy plain, with hill country in the S. and E. Except in the N.E., where Devonian sandstone and limestone occur, the formations are Lower Tertiary, consisting of layers of clay-slates, gravelly sandstone, coarse limestone, lignite, and marl. The rivers run to the Niemen, which forms the W. and part of the S. boundary, and whose chief tributary, the navigable Vilia, crosses from E. to W. the middle of V., while the Disna flows N.E. to the Düna on the N. border. There are in V. 400 small lakes, and numerous wooded marshes. Pine-woods, in which are found the elk, bear, wolf, boar, and glutton, cover 38 per cent. of the surface. The cereal products are rye, oats, buckwheat, and barley, the trade in which, as in wood, pitch, tar, turpentine, honey, and wax, is chiefly in the hands of Jews. V. is traversed by the St. Petersburg-Warsaw Railway. —**V.**, the capital, is situated on the Vilia, 42½ miles S.S.W. of St. Petersburg by rail. It has narrow and irregular streets, 18 squares, 2 large suburbs, called *Antokolla* and *Rudaishka*, a ruined castle, an imperial palace, a theatre, and the Oginski Palace, which is now used as government buildings. Of its churches 35 are Catholic (including the cathedral, with the tomb of St. Casimir and the great churches of St. John and St. Peter), 6 Russo-Greek, and 3 Protestant. There are also a synagogue, a mosque, and several Catholic and 2 Greek monasteries. The university, founded in 1576, was abolished in 1832, when the greater part of its library, observatory, and scientific collections were removed to St. Petersburg and Kiev. The other chief educational institutions of V. are a Catholic Priests' College, a Lithuanian Orthodox Priests' College, a Rabbinical School, a classical gymnasium, and 3 Hebrew schools. It has also an antiquarian museum, a deaf and dumb institute, and an orphanage, several factories and distilleries, and an active trade. V. is a very old town. In the heathen period it was a holy place. In 1387 Jagellon here introduced Christianity, and built the cathedral on the site of the old heathen temple. Pop. (1875) 64,200 (about 20,000 Jews).

Vinaroz', a town of Spain, province of Castellan, at the mouth of the Servol on the railway between Valencia and Tarragona, has some small trade in salt, oil, and wine, besides the building of fishing-boats. Pop. 9200. In November 1810 the French general, Musniers, defeated the Spanish army here.

Vin'ca. See PERIWINKLE.

Vincennes', or **La Pisotte'**, a fortified town and celebrated château of France, department of Seine, in an easterly direction from Paris by rail, 5 miles distant from the Louvre, near the right bank of the Marne, in the famous Bois de V. The town is in reality a great fortress, and has a large artillery work and park, a cannon-foundry, an arsenal, powder-magazine, and an École de Tir, at which officers of all regiments learn the use of arms, and to which the garrisons of Paris, &c., send contingents for practice. There are some manufactures of caoutchouc, starch, chemicals, leather, &c. Pop. (1872) 17,064. The château is in form of parallelogram, 1200 by 670 feet. An interior fort, known as the Donjon of V., is 170 feet high, and has walls 17 feet thick; it was originally flanked by nine towers, all of which,

except one, were removed when the building was being remodelled as the chief arsenal for Paris in 1818. The original building dated from 1137, and was used as a hunting-lodge by Louis VII. Begun by Philippe de Valois in 1333, the present château underwent expansion and change at various times, but was used as a royal residence till the time of Louis XV. The Duc d'Enghien was shot here. The Bois, which is adorned with lakelets, avenues, &c., covers an area of 4 square miles, and is a favourite resort of middle-class Parisians.

Vincennes', a city of Indiana, U.S., on the Wabash, 100 miles S.W. of Indianopolis by rail. It contains 10 churches, numerous schools, a 'university,' 2 bi-weekly and 3 weekly newspapers. Standing in a rich agricultural district, it has many large flouring-mills and some machine-works. V. is an important railway centre. Pop. (1870) 5440. It was settled by the French in 1702.

Vin'cent, St. See ST. VINCENT.

Vin'cent de Paul, St., founder of the great order of Sisters of Charity, was born at Pony in Guyenne, 24th April 1576. The leading impulse of his nature was pity, and so much was V.'s father struck with this, that he took him from herding sheep and sent him to be educated for the priesthood, into which he was admitted in his twenty-fifth year. He at once resigned all pretensions to a rich living to which he was presented because his right was disputed. On a voyage from Narbonne to Marseille he was captured by pirates and carried to Tunis, where he passed three years in slavery. The last of three masters he had was so affected by the piety of V. that he fled the country with him, the two arriving safely at the shores of France in a small boat (1607). Proceeding to Avignon to represent the sufferings of the European slaves in Africa to the Pope's legate, he was taken by the latter to Rome, where he was entrusted with a commission to the French king, Henri IV., who wished to make him a bishop. Through the influence of Cardinal de Berulle, who was deeply touched by the labours of V. for the inmates of an hospital, he was appointed almoner to Queen Marguerite de Valois, and to the Abbey of Chaume. But those preferments he soon resigned, in order to become pastor of Chatillon, near Lyon, because the living was so poor that no one would accept it. Having been persuaded to undertake the education of the children of the Marquis de Condi, he employed his leisure, when in the country, ministering to the peasantry, and when in the capital, visiting the galley-slaves. So much was he affected by the condition of the latter, that he set out for Marseille to act as a missionary among them, and even on these degraded criminals his teaching and example had a wonderful effect. There was one, however, whom he could not teach resignation, and he procured his release by taking his place for eighteen months. On his release he accepted the living of Chichi, and was appointed by Louis XIII. almoner-general of the galley-slaves. He next appears at the head of a vast organisation for establishing missions in France and foreign countries. In 1634 he founded the order of Sisters of Charity, which was recognised by the Pope in 1655. See BROTHERS AND SISTERS OF CHARITY. He did much to ameliorate the condition of the beggars of Paris, of the galley-slaves, and of the captives in Barbary (after spending 1,200,000 lires in redeeming so many); he sent alms and missionaries to the Hebrides, Poland, and Madagascar; and succoured the Maronites (q. v.), and the English Catholics during the Commonwealth. He was appointed extraordinary confessor to Louis XIII. on his death-bed, and after the death of that monarch head of the Conseil de Conscience. V. de P. died at St. Lazare, 27th September 1660, and was canonised in 1737. See Ansart's *Life of St. V. de P.* (New York 1868), and another edited by Canon Wilson (Lond. 1873).

Vin'dhya Mountains, a range of hills which extend across Central India, almost due E. and W. from the plateau of Chota Nagpur, overhanging the basin of the Ganges, to the shores of the Arabian Sea in Gujerat. Their total length is about 500 miles, and the highest peak does not exceed 6000 feet. The formation is granitic overlaid with sandstone. They form on the N. a continuous border to the Nerbudda, and with that river they are regarded as forming the traditional boundary between Hindustan proper on the N. and the Deccan on the S. The 'fourfold girdle round the waist of India' is completed by the Satpura range and the Tapti river.

Vine (*Vitis*), an extensive genus, numbering about 250 described species of climbing plants belonging to the natural order *Ampelideæ*. The branches are swollen at the nodes, separating from each other by an articulation; tendrils (abortive inflorescent branches) and the inflorescence are leaf-opposed; leaves alternate, or the lowest opposite, either simple and entire or lobed, or compound; flowers numerous, small, greenish, cymose, those of the Eastern species hermaphrodite, those of the Western incomplete and frequently diœcious; calyx somewhat 5-toothed; petals 5 or 4 cohering at the top, often lifted up by the stamens (equalling them in number), and falling off without expanding; ovary sessile, 2-celled; fruit a 2-celled globular berry; the cells 2-seeded, but by abortion often 1-celled and 1-seeded. The majority of the species are natives of tropical and temperate Asia as far N. as Japan, tropical Africa, and N. America, while none are confidently recognised as indigenous to Europe. The best-known and most important species is *V. vinifera*, the grape V. It is indigenous in Armenia, the Caucasus, other parts of W. Asia, and possibly also in Bulgaria, Thracia, and Greece. In the N.W. Himalaya, also, this V. is often found apparently wild, but wherever cultivated under favourable climatic conditions it spreads rapidly. It is certain that its cultivation in Syria and Greece is as old as the oldest historical records of those countries; that Greek colonists and traders imported it into Italy at an early age; that from W. Asia and S.E. Europe its cultivation has spread over other portions of Europe; and that from Europe it has been introduced to the Azores, Madeira, the Cape, Australia, and N. America. The present northern limit of vineyards on a large scale is 47° 30′ N. lat. in the Bretagne, and thence runs eastward, slightly tending towards the N., crossing the Rhine at 50° 45′, and attaining its northernmost point in Silesia at lat. 51° 55′. The comparison of this line with the lines of equal temperature during the different seasons, shows that it is the want of sufficient summer heat which prevents its profitable cultivation further N. in Western Europe. In the Middle Ages, however, there were vineyards in the S. of England, and not far from the Baltic. Excellent grapes are grown in parts of India. The mode of cultivation of the V. varies in different countries. Success is chiefly dependent on a good sunny exposure, liberal but not coarse manuring, and constant attention. New varieties are raised from seed, but the ordinary modes of propagation are by layers and cuttings. Fine varieties are budded or grafted on strong-growing stocks of inferior varieties. In British vineries the V. is carefully trained in various ways on walls and trellises, the superfluous shoots are removed by pruning so as to direct strength to the fruit-bearing branches, and the foliage is thinned so as to give free access to light and air. The luxuriant growth of the plant renders the frequent application of the pruning-knife necessary during summer. Few plants more readily adapt themselves to surrounding circumstances than the V., but for the production of grapes of the finest quality certain conditions must be complied with—(1) The soil in which the plants are growing, and, if possible, the subsoil also, must be free from stagnant water; (2) the soil must be free and porous; (3) it must be free from rich, raw, and stimulating manures, but contain sufficient stimulant of a permanent character, such as bones, charcoal, and burnt earth, to yield the food necessary for the proper and constant sustenance of the plant. The V. mildew (see OIDIUM) and the insect pest Phylloxera (q. v.) have in recent years caused great loss to V. growers. The most important products of the grape V. are wine and vinegar, the one obtained by vinous and the other by acetous fermentation; brandy, a product of distillation; and raisins and currants, which are both the dried fruits. Grapes are sent to Britain in large quantities from France, Spain, Portugal, and Holland, generally packed in sawdust, and are retailed at a cheap rate. The home-grown hothouse grapes always command a proportionally high price. The wood of the V. is remarkable by its numerous large medullary rays and exceedingly numerous pores, giving it the appearance of a sieve. In spring it yields an abundance of clear watery sap, which rises with great force, and in France is a popular remedy for chronic ophthalmia. The leaves on account of their astringency have been used in diarrhœa.

Among other species of *Vitis* claiming notice are the following:—*V. acetosa* of N. Australia, which has proved valuable in cases of scurvy; its berries are edible. *V. Baudiniana* of E. Australia, the most southern-growing species; it fruits freely, and the berries though small are edible. *V. cordifolia* of Canada

and United States is noted for the exquisite scent of its flowers; the fruit is used for preserves. *V. hypoglauca* of E. Australia, an evergreen climber of enormous length; the black berries attain the size of cherries. *V. Indica* of mountainous districts in India; berries small but edible. *V. quadrangularis*, common through tropical and sub-tropical India; berries very acid, leaves and tender shoots eaten. *V. Labrusca*, the Isabella grape of N. America; the berries are pleasant-tasted, and large among American kinds; several varieties are grown, and are not liable to the oidium disease. *V. Schimperiana* is a representative of African grapes, and may hereafter prove serviceable. *V. vulpina*, the Muscadine or fox-grape of the S.E. United States, includes several cultivated varieties of America; the fruit has a pleasant taste, and is of large size (see Planchon's *Les Vignes Americaines*, Par. 1875). The pigment of the purple grape is known as Oenolic acid; the juice contains tartaric acid and grape acid. See Babo, *Der Weinstock und seine Varietäten* (new ed. Frankf. 1857); Roth, *Der Rheingauer Weinbau* (Frankf. 1878); and Vizitelly's well-known work (new ed. 1879).

Vin'egar is a solution of Acetic Acid (q. v.), usually containing from 2 to 5 per cent. of acid, and minute proportions of various ethers and other substances according to the sources whence it is derived. V. is a product of the oxidation of alcoholic solutions, and may consequently be prepared from any body containing alcohol, or capable of being transformed into that substance. In practice it is prepared from malted barley or other grain (malt V.), from wine of inferior quality (wine, French or Orleans V.), from dilute solutions of spirit (spirit V.), and from cider (cider V.). Wood V., a product of the destructive distillation of wood (see PYROLIGNEOUS ACID), is used chiefly in connection with chemical operations, and although deficient in flavour and other qualities it is in extensive use as a table V., and for the various other purposes to which common V. is usually applied. The circumstances which are necessary for and favour the production of V. are, 1st, an alcoholic solution (or a solution capable of developing alcohol) containing not more than 10 per cent. of spirit; 2d, a suitable temperature, which may range from about 45° to 100° F.; 3d, free access of atmospheric air; and, 4th, the presence of substances which promote acetification or oxidation of the alcoholic solution, the chief active agency being the V. fungus *Mycoderma aceti*, which acts as a carrier of oxygen to the solution. There are two principal processes by which ordinary V. is prepared, termed respectively, 1st, the old or slow process; and, 2d, the quick process. The slow process is still largely used in the preparation of French or wine V., and it is also used in making British malt V. In the manufacture of the latter there are a number of preliminary operations analogous to those employed in brewing. A mash of mixed malt and unmalted barley is prepared, and the wort is permitted to ferment. After completion of the fermentation the liquor is run into barrels, the tops of which are open but tied over with coarse canvas, and stored away in darkened but moderately-heated chambers where there is free access of air. There the acetous fermentation takes place slowly during several weeks or even months, when the contents of the barrels are emptied into two large tuns having false bottoms, over which the pressed cake from making currant wine, &c., is strewed. One of the tanks is filled entirely, but the second is only three-fourths filled. Here the acetous fermentation proceeds vigorously, and when the V. is ready a portion is drawn from the second (unfilled) tun. The quantity withdrawn is made up from the full tun, and it again is filled up from the barrels. In this way the manufacture goes on progressively. The old or slow method of V.-making is a system requiring extensive premises and plant, and to a large extent it is now supplanted by the new or quick process. The principle upon which the various quick methods in operation depends consists in exposing the alcoholic solution at a favourable temperature in the most intimate manner to the action of the atmosphere. The solution is made to trickle drop by drop through one or more columns containing beech shavings or other means of fully exposing the fluid to the air, and as it descends it meets a current of air ascending. In this way rapid and complete oxidation is promoted. V. on a domestic scale is prepared from saccharine solutions to which the V. fungus *Mycoderma aceti* is added, the solution being covered up and kept in a warm place till the acetification is complete. The use of V. in the manufacture of pickles, the preparation of salads, and of acid beverages, as well as directly as a sauce with animal food, is very extensive. It is also an important substance in medicine, both for internal and external use, and its pungency combines in a very refreshing manner with various perfumes for toilet purposes. V. is a valuable aid to the digestion of the hard fibrinous and albuminous constituents of food. The qualities of V. depend principally on the source whence it is obtained, the best being wine V., after which comes that prepared from pure malt. Inferior V. is frequently contaminated with sulphuric acid, of which by law one part per thousand is permitted to be present without being counted an adulteration.

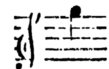
Vin'egar Eel (*Anguillula aceti*), a small species of *nematoid* worm, inhabiting vinegar. The V. E. is one of the 'free' or non-parasitic nematoids. The young are produced in large numbers, and frequently by a process analogous to asexual methods of reproduction.

Vin'egar-Plant is the name popularly given to the fungus mass that covers the surface of liquids during the process of acetous fermentation, and which, if placed in a solution of sugar in water and kept at a proper temperature, assists materially in converting the mixture into vinegar. The V.-P. consists of interlaced delicately-branched threads, and under favourable conditions for development produces a common mould known as *Penicillium glaucum*. See MOULD.

Vine'land, a town of New Jersey, U. S., 34 miles S. of Philadelphia by rail. With the exception of a few blocks in the main avenue, the town is laid out in fruit-farms of from 5 to 25 acres, and resembles a vast park. It has 10 churches, numerous schools, flour, wood, machine mills, &c. There are 2 daily and 4 weekly newspapers. In 1875, 345,791 quarts of berries, 23,784 crates of peaches, and 1,210,188 pounds of grapes were exported. Pop. (1870) 11,000. V. was founded by Charles K. Landis in 1861 on 'temperance' principles. The cultivation of fruit forms the chief industry.

Vi'net, Rodolphe Alexandre, born at Ouchy, June 17th, 1797, and educated at Lausanne. As early as 1814 a patriotic song from his pen, *Le Reveil des Vaudois*, became popular. In 1817 he was called to teach French at the gymnasium, and 'pædagogium' of Basel, and two years later he became a minister of the national church. About this time a religious 'revival' was taking place in this part of Switzerland. At first V. wrote against the movement, but before the close of 1823 he had completely changed his views, and in 1824 he took up the cause of the much-persecuted dissidents in his *Respect des Opinions*. The general principles of religious liberty enunciated in this little work received fuller treatment in a *Mémoire en Faveur de la Liberté des Cultes* (Paris 1826), in which he claimed that there should be the completest severance of Church and State. In 1835 he was appointed professor of French literature in the university of Basel, and in 1837 he removed to the chair of practical theology in Lausanne. Two years later, on the enactment of the law of 1839, by which the Church was made more dependent than ever on the State, V. renounced his clerical status, and in 1845 he gave up his theological professorship, but was almost immediately appointed to the chair of French literature. In 1846 his co-operation with the 'free church' movement led to his ejectment. He died at Clarens, near Vevey, 4th May 1847. Among the more remarkable of V.'s works are *Études sur la Littérature Française au XIX. Siècle* (Par. 1849–51, 3 vols.); *Études sur Blaise Pascal* (Par. 1848; 3d ed. 1876); *Hist. de la Litt. Franç. au XVIII. Siècle* (Par. 1853, 2 vols.); *Moralistes des XVI. et XVII. Siècles* (Par. 1859); *Hist. de la Predication parmi les Réformés de France* (Par. 1860). See Fred. Chavannes, *Alex. V., Notice et Mémoires* (Neuchâtel 1847); Sainte-Beuve, *Derniers Portraits Littéraires*, vol. ii.; Scherer, *Alex. V., Notice sur sa Vie et ses Écrits* (Par. 1853); E. Rambert, *Alexandre V.* (3d ed. 1877); and Montet, *Dict. Biographique des Genevois et des Vaudois* (Lausanne 1878).

Vin'land ('wine-land'), the name applied by the Northmen to that part of the E. coast of N. America which includes Massachusetts and Rhode Island. It was first discovered in 986 by Bjarne Herjulfsson on his voyage from Iceland in quest of his father, who had gone with Erik the Red to Greenland; but it was not till 1000, when Leif the Lucky, a son of Erik, sailed on a voyage of discovery with Bjarne's ships and a crew of thirty-five men, that the Northmen landed upon the conti-



nent. The first land they touched being rocky and icebound, they named Helluland ('rock-land'); the next, further southwards, Markland ('wood-land'). Sailing still further southwards, they landed upon a coast where one of the sailors, a German named Tyrker, found the vine growing, from which the country was called V. Here Leif and his sailors built themselves wooden huts ('Leifsbudir'), and remained until the approach of spring, when they sailed to Greenland, their ship laden with grapes and building-timber. Seven years later, Thorfinu Karlsefne led 160 men to settle in V., but after staying three years the colonists returned to Greenland. The connection, however, was kept up to the 12th c., as it is known that Erik, first Bishop of Greenland, visited V. in 1121. The visit of Columbus to Iceland in 1477, which has been satisfactorily established by Finn Magnusen, is especially interesting from the probability that there he may have heard of the existence of land beyond the Atlantic, and have had his ambition roused to follow in the track of the old Northmen, fifteen years before he became the discoverer of America. See Rafn, *Antiquitates Americanæ* (Copenh. 1837), and Wilhelm, *Hvitrammanaland, Grönland und V.* (Heidelb. 1842).

Vinnit'za, a town of Russia, government of Podolia, on the river Bug, 45 miles N.N.W. of Odessa by rail. It has six churches, a Russo-Greek monastery, a Capuchin monastery, two synagogues, several schools, and a military hospital (formerly a Jesuit college). Pop. (1875) 18,780.

Vin'sauf, Geoffrey de. See GEOFFREY DE VINSAUF.

Vi'ol (Ital. *viola*; Med. Lat. *vitula*), a stringed instrument played with the bow, which preceded the violin. The Spanish V. of the 12th c. was called a vilhuela, and resembled a rebec. The latest form of the V. was a flat instrument, with larger curves at the side than the violin, and with a fretted finger-board, manipulated by the left hand. It had from 3 to 6 strings, which were probably tuned in fourths and thirds. In the 17th c. the most popular bow instruments were the treble, tenor, and bass viols, and V.-players usually had chests containing six viols of different sizes and pitch. In Germany the various kinds were called the bratsche, the schultergeige, and the bassgeige. In Italy the smaller kind of V., from being held by the arms, was known as the 'V. di braccio;' and the larger, which rested between the knees, the precursor of the violoncello, the 'V. da gamba.' The 'Viola Pomposa' was a species of V. da gamba invented by J. Sebastian Bach.

Vi'ola, the tenor violin, a musical instrument holding a position between the second violin and the bass. It is the German *bratsche*, and is sometimes called the *alto* V., from the music being written for it in the alto clef. It has four strings, the two lower of which are covered with silvered copper wire, tuned in fifths, thus one octave above the violoncello. Its compass ranges from to

Vi'ola d'Amo're, an almost obsolete instrument of the violin class, which had from five to seven metal strings under the finger-board, in addition to the same number of ordinary catgut strings, producing a peculiar sweetness and delicacy of tone. Those metal or sympathetic strings were tuned in unison or in octave with the others, and required to be made of wire of an exceeding thinness very difficult to obtain. The instrument had a compass of about 3½ octaves, and was usually tuned thus

Meyerbeer and Berlioz endeavoured to revive its use in the orchestra, the former composer having written an obligato part for it in the first act of the *Huguenots*.

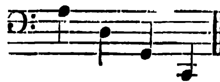
Vi'olent Prof'its are, in Scotch law, the income from heritable (real) estate, during the forcible detention of it by a tenant after he ought to have given it up. In an action for removing, a tenant is usually required to find security for the V. T.

Vi'olet (*Viola*) is the type genus of *Violaceæ*, a natural order containing 21 genera and about 250 species of herbs or shrubs distributed through temperate and tropical regions of both hemispheres. It belongs to the thalamifloral subdivision of dicotyledons, and is distinguished by having alternate stipulate leaves; irregular often showy flowers with 5 sepals, 5 petals, and 5 stamens; the ovary is 1-celled, with parietal ovules; style 1; capsule 3-valved; seeds albuminous. The properties are emetic and laxative, and the root of *Ionidium Ipecacuanha* and *I. microphyllum* is used medicinally in Brazil and Venezuela. The order does not enter into British Pharmacopœias. The genus *Viola* numbers upwards of 100 species, represented in all temperate countries, and contains several familiar plants. The pansy of the gardens is the result of continued cultivation and crossing of several species of V., one of which, the common heartsease (*V. tricolor*), is an abundant and variable plant of cornfields, &c., in Britain, and others are *V. altaica* from Siberia, and *V. calcarata*, a native of Central Europe. Florists demand that a show pansy shall measure fully 1½ inches across, have a flat, round, and very smooth edge, the petals thick and velvety, the lower three alike in their ground colour with bright and distinct pencillings, and the two upper perfectly uniform. The sweet-scented V. (*V. odorata*) is another favourite. It is spread over Europe, N. Africa, and Western Asia to the Himalaya, is wild in England, but does not appear to be native in Scotland. Numerous forms and varieties of it are grown for the delicate fragrance of the flower, and the plant is extensively cultivated for perfuming purposes. The name dog V. is popularly applied to the scentless violets of the same group as the sweet V., the cognomen denoting their worthlessness. The name therefore includes the several species that along with the primrose so profusely deck the banks and open woods through Britain in the spring months. V. is used in conjunction with some other word for several plants not belonging to the genus *Viola*. For water V. see HOTTONIA. Dame's V. (q. v.) is a cruciferous plant, and the dog's-tooth V. (*Erythronium dens-canis*) belongs to *Liliaceæ*. The V. is the emblem of the Napoleon family.

Vi'olin (diminutive from *viol*), the most perfect of solo musical instruments, stringed, and played with a bow. It consists of a wooden chest formed by two slightly curved surfaces—the belly and back—united by sides or ribs hollowed at the half length, to which is appended a neck or finger-board. Four strings of thin gut, the fourth being covered with silver wire, are stretched from a tail-piece at the foot of the chest to the head of the finger-board, where they are received by turning-pins, which tighten or loosen them at pleasure. The strings are raised above the belly by a bridge, convexly curved, so that the bow may be drawn across each separately. The belly is usually made of soft deal and the back and sides of maple. The excellence of a violin depends greatly upon the thickness and collocation of the wood and the nature and direction of the curves. The grain of the wood should be very regular. A certain fixed relation should always lie between the air-bearing capacity of the chest (as fixed by the height of the sides or ribs) and the thickness of the wood. There are two sound-holes in the belly in the shape *f* *f*. The outside of the instrument is varnished while the inside is plain. The outer coat of varnish drives the sound inwards, whence it escapes through the sound-holes. The bow, which is held in the right hand, is strung with horse-hair powdered with rosin.

The V. is tuned in fifths, thus—

Every intermediate semitone in its ordinary compass of 3½ octaves (from to may be produced by stopping the strings. Chords of two notes may also be played, and several notes in arpeggio. The compass may be almost indefinitely extended upwards by the harmonics produced by touching the strings lightly. The violin has great capabilities of execution, and a power of expression quite unparalleled, every gradation of quality and tone being obtainable from it. It is the



most susceptible and sympathetic of instruments, following the ideas and caprice of a master with astonishing fidelity and marvellous completeness. The sound may be modified by the use of the mute or sordino. The effect produced by plucking the strings with the fingers in guitar fashion is called *pizzicato*.

Not only does the V. play an important part in solo music. In its two forms, 1st and 2d V., and with its kindred instruments the viola and the violoncello, it forms the basis of all orchestral music, the string quartette being indispensable to a musical score. Many of the finest works of the great masters have been written for these four instruments alone.

The invention of the V. has been claimed by various nations, but strings stretched across wood were probably found a pleasing method of producing musical sounds at different periods and places independently. The Hindus have a bow instrument of great antiquity, names for it occurring in Sanskrit, a language which ceased to be spoken about 300 B.C. They maintain that the revanastron, of which the modern representative is the chikarah, was invented 5000 years ago by Ravanon, a king of Ceylon. The Chinese have an ancient instrument with two strings, played from below with a bow, but with no finger-board. The rehab, the kermangeli, the Scandinavian gaddok, the Welsh crwth, the rebec, the Old English fithele (the fiddle), are varieties of the precursors of the V. In the rebec we have the rounded form and the sound-holes, in the crwth the important detail of the back and belly joined by two sides, in the guitar the elongated neck. There is a drawing in an MS. in the British Museum of an Old English fithele of the 11th c. of pear-shape, with 4 strings and no indication of a bridge. In the 16th c. the V. seems to have been elaborated from the viol. A V. dated 1578, given by Queen Elizabeth to the Earl of Leicester, is essentially the same with that now in use. Gasparo di Salo of Brescia was the first great Italian maker. Andreas Amati was the founder of the illustrious Cremona school. His reputation was maintained by his sons Jerome and Antonius, and excelled by Nicolas the son of Jerome, who produced violins of an unprecedented mildness and sweetness of tone. But the greatest of all makers was his pupil Stradivarius or Stradivari (q. v.), who by unwearied experiments and dexterous manipulation attained an excellence never since equalled. His violins are of exquisite beauty and perfect workmanship. The improvements he made upon the Amatis violin, in the size and shape of the chest and the sharp and beautifully cut sound-holes, have become permanent. His varnish has a reddish tinge instead of the yellow used by Amatis. The sound of a Stradivarius V. has a splendid richness and fulness. The classic signature 'Antonius Stradivarius, Cremonensis, faciebat, Anno,' has often been forged, but no imitation can deceive the expert, or can approach the finish of the genuine work. Jacob Stainer, a Tyrolese, was a maker of great reputation, and his high and narrow violins are still much valued for their sharp and piercing tone. Although the V. is so sensitive as to require tuning on every occasion, and to feel every change of weather like a barometer, it is of great hardiness, can stand almost any amount of wear and tear, while age and constant use seem to improve it rather than the reverse. Those by the great makers fetch sometimes as high sums as £500. The most celebrated modern factory is that of Villaume at Paris. See Otto's *Treatise on the Structure and Preservation of the V.*, Sandys & Forster's *History of the V.*, Fetis' *Antoine Stradivari, précédé de Recherches historiques et critiques sur l'origine, &c., des Instruments à Archet* (Par. 1856), Haweis' *Music and Morals* (2d ed. Lond. 1873), George Hart's *The V.; its famous Makers and their Imitators* (Lond. 1875), Niederheitmann's *Cremona* (Leip. 1877), and Vidal's *Les Instruments à Archet* (2 vols. Par. 1876–77).

Vi'ollet-le-Duc, Eugène Emmanuel, born in Paris, 27th January 1814, studied ancient art at Rome and Taormina (1836–37) as well as in the cities of Southern France, and in 1840 was charged with the restoration of the exquisite Sainte Chapelle. Since then he has been employed on many of the historic monuments of Gothic art in France, notably Notre Dame (1846), and as engineer he assisted in the defence of Paris (1870–71), while playing in politics the part of a hot republican. He is author of *Dictionnaire raisonné du Mobilier Français de l'époque Carlovingienne à la Renaissance* (6 vols. 1854–72), *Lettres sur la Sicile* (1860), *Chapelles de Notre Dame de Paris* (1869), and *L'Art Russe* (1877); and other works by him have been translated under the titles *Military Architecture of the Middle Ages* (1860), *How to Build a House* (1874), *Annals of a Fortress* (1875), *Habitation of Man in all Ages* (1876), *Lectures on Architecture* (1877), and *Mont Blanc, its Geodesical and Geological Constitution* (1877). His pamphlet on *Restoration* (Eng. trans. 1876) contains a survey of his architectural undertakings.

Violoncello (the little violone or double bass) is a large stringed musical instrument, held by the performer between the knees, and filling a place between the violin and double bass. Its tone is powerful, and in the higher register most sympathetic, while it has a resource almost equal to the violin, which it closely resembles in construction. It supplied the place of the bass viol or viol da gamba. It has four gut strings, the lower two being covered with silver wire. It is tuned in fifths one octave lower

than the violin, and has an ordinary compass of from

Soloists can play an octave higher. The signature is in the bass clef, the tenor or treble being used for high notes. It is usually coupled in the orchestra with the double bass, and as it gives rapid passages with more certainty than the latter instrument, the intermediate notes of a passage are generally assigned to it, while the double bass takes the essential.

Viott'i, Giovann'i Battis'ta, a master of the violin, was born in Piedmont, 23d May 1753, and in early life was first violinist in the chapel royal at Turin. In 1778 he undertook a professional tour through Germany and Russia, and four years later took Paris by storm with his brilliant execution, and the finish, energy, and grace of his style. He removed to London on the Revolution, where he created a similar sensation, and ultimately became leader of the orchestra at the King's Theatre. In 1798 he had to leave this country on an ill-founded suspicion of holding revolutionary views. After a residence in Hamburg he returned to London, where he died, 10th March 1824. V. composed twenty-nine concertos for the violin, and a great number of string quartets, trios, &c.

Vi'per (Lat. *vipera*, from *vivus*, 'alive;' *pario*, 'to bring forth'), the name given to the adder (*Pelias berus*), the only poisonous British snake, from its habit of retaining the eggs within the body until the young are hatched. This snake is therefore said to be *ovo-viviparous*. The V. is typical not merely of a sub-order (*Viperina*) of the order *Ophidia* (or that of the snakes), but also of a family *Viperidæ*. The sub-order *Viperina* is distinguished by the absence of true teeth in the upper jaw, this bone bearing merely two *canaliculated* poison-fangs, with a few rudimentary teeth behind, destined to replace the latter in event of their being lost or injured. The fangs are capable of being erected or depressed at will. They communicate internally with a poison-gland, the contents of which are ejected through the canal of the fang into the wound they inflict. The lower jaw has numerous solid teeth of ordinary shape and form. The head of the viperine snake is broad at the middle, and is separated from the body by a well-defined neck, while the head is covered with small scales. The family *Viperidæ*, to which the vipers and their typical allies belong, is distinguished by the shields or scales of the belly being large and arranged in band-like fashion, while the head has no pit or depression between the eye and nostrils.

Of the V. family the best-known example is the Common V. above named. Its average length is about 18 inches. Its colour varies, but is usually an olive-brown, marked along the back with a prominent series of black zigzag markings. These serve to distinguish the V. from the Common Snake of Britain. The sides are also marked with small triangular black patches. The bite of the V. is not necessarily fatal, save to weakly persons and to children. The food of the V. consists of mice, frogs, birds, &c. The eggs are deposited at the beginning of summer, and number about 20.

The name 'V.' as a generic term is given to such serpents as the Water V. (*Cenchris piscivorous*), a common American snake, which lives in water and feeds on fishes. It attains a length of 2 feet, and is of a greenish brown, marked with black,

The Horned V. or horned adder (the *Cerastes Hasselquisti* of N. Africa) gets its name from the horn-like scale which protrudes over each eye. The Death V. (*Acanthophis Antarctica*), an Australian snake, is named from the fatal effects of its bite.

Viper'idæ. See VIPER.

Vi'per's Bu'gloss (*Echium*), a genus of *Boraginaceæ* numbering twenty species of usually large herbs (sometimes shrubby) rendered hispid or scabrous by an abundance of tuberous-based hairs. The leaves are entire; the flowers white, red, purple, or blue, in spiked or panicled racemes; the calyx five-partite; the corolla irregular, open at the throat; the stamens exserted; the style filiform. The genus predominates in the Mediterranean region and the Orient; shrubby species are met with in the Canaries and in S. Africa, and are highly ornamental. *E. vulgare* is one of the most showy of British native plants, and is of frequent occurrence in light soils. Its seed bears a miniature resemblance to the head of a viper—hence the name V. B.

Virch'ow, Ru'dolf, was born 13th October 1821, at Schivelbain, in Pomerania, and received his medical education in Berlin, where he was a favourite pupil of Johann Müller's. He was rapidly rising into fame as a lecturer in the Berlin University when his political action deprived him of his official appointments (1849). He was at once called to be professor of pathological anatomy at Würzburg. In 1856 he returned to Berlin, where he still continues to take equal interest in science and politics. As a scientific man he is the founder of cellular pathology, and has done immense service by his discoveries in regard to inflammation, ulceration, tuberculosis, and a hundred other morbid processes of the human frame. As a politician he is a strenuous Liberal, and in the Prussian Parliament, to which he was called in 1862, he has been one of the most powerful opponents of Bismarck, who in 1865 after the defeat of the Navy Bill challenged him to a duel. It is to V. that Germany is indebted for the word *Kulturkampf* as a designation of the great political struggle of the time. He was one of the founders of the German Anthropological Society in 1869. Since 1856 he is an honorary member of the Royal Society of Medicine of London, since 1859 a corresponding member of the French Academy of Medicine, and since 1873 a member of the Berlin Academy of Sciences. V. has been a voluminous writer. Among purely scientific works are *Cellular Pathologie* (4th ed. Berl. 1871; English trans. Lond. 1860); *Abhandlungen zur Gewissenschaftlichen Medicin* (Frankf. 1856); *Ueber Die Entwickelung des Schädelgrunds* (Berl. 1857); *Ueber den Hungertyphus* (Berl. 1868; English trans. Lond. 1868). Of more general interest are *Die Aufgabe der Naturwissenschaften in dem neuen Nationalen Leben Deutschlands* (Berl. 1871); *Die Freiheit der Wissenschaft im modernen Staat* (Berl. 1877).

Vire, a town of France, department of Calvados, stands 168 miles W. of Paris by rail. It has important manufactures of cloth, paper, and glass, and carries on a trade in hides and wool. Pop. (1872) 6778. In the immediate neighbourhood is the beautiful valley, Vaux de V.

Vi'ret, Pierre, a Huguenot theologian, born at Orbe in the Pays de Vaud in 1511. Along with Farel (q. v.) he was one of the earliest preachers of the Reformation in Switzerland. Having held ministries at Geneva and Lausanne, he was summoned towards the close of his life by the Queen of Navarre to teach theology at Orthez, where he died in 1571. A brilliant orator and vehement writer, V. was the author of *Exposition Familière sur le Symbole des Apôtres* (1543), *Disputations Chrétiennes* (1544), *Satyres Chrétiennes de la Cuisine Papale* (1560), &c. See Jacquemot, *V., Réformateur de Lausanne* (Strasb. 1836).

Virgil'ius (properly **Vergil'ius**) **Maro, P.,** the greatest of the Roman poets, was born at Andes (now *Pietola*), a hamlet about 2 miles from Mantua, on the 15th October 70 B.C. He received his first education at Cremona, whence, after assuming the *toga virilis* at sixteen, his father, a small landed proprietor, sent him to Milan, and finally to Rome. There he at first studied rhetoric under Epidius, but soon finding himself unfitted for the bar, turned to philosophy and natural science under the Epicurean Siron. His love for these studies is amply proved from his writings, and he is said to have purposed, after the completion of his *Æneid*, to devote to them the remainder of his life. Before the outbreak of the civil war in 49, V. had returned to Andes, where he continued till 41, when his father's property was seized in the division of lands among the soldiers of Antonius. V. appealed to C. Asinius Pollio, legate of Antonius in Transpadane Gaul, who gave him letters of recommendation to Octavianus, which soon procured for him an order for the restoration of his farm. But within a year it was again torn from him, and V. retired with his father to the villa of Siron, near Rome. Mæcenas soon after became his patron, and Octavianus either restored his lands or gave him new. Henceforth the friendship of Mæcenas and of the Emperor secured him leisure and a competence, and he lived chiefly at Naples, sometimes at Rome, in a house near that of Mæcenas, on the Esquiline. Hard study enfeebling his naturally weak constitution prepared his early death, which befel at Brundisium, 21st September 19 B.C., on his return from a stay in Greece. He was buried within the second milestone on the road from Naples to Puteoli. He left half of his estate to his half-brother, one-fourth to Augustus, and the rest he divided equally between Mæcenas and his friends Varius and Tucca. V. was tall and slender, of dark complexion and plain features, slow of speech, and shy and retiring of disposition. By 38 he had published his *Bucolica*, probably in the received order, while most likely the order of their composition was as follows: 2d, 3d, 5th, 1st, 9th, 4th, 6th, 8th, 7th, 10th. These *Eclogæ* are sweet and elegant short poems, full of complex beauty and varied music. With them V. founded the *artificial* school of pastoral poetry, and in them he bears the same relation to his model Theocritus that Pope (as a pastoral poet) does to Allan Ramsay, or Shenstone to Burns. In Italy they have been imitated by Tasso and Guarini, in Spain by Garcilaso de la Vega, in France by Florian, and among English poets by Spenser, Milton, Drayton, Drummond, Pope, Shenstone, Phillips, and Gay. At Mæcenas' instance V. began his *Georgica* about 37. It was published about 31. This highly-finished work, which V. himself calls an Ascræan (*i.e.*, Hesiodic) poem, and Dean Merivale 'The Glorification of Labour,' gives its author the unquestioned title of prince of didactic poets. Much of its spirit and poetry is drawn from Lucretius, but it is original in its idea, its fine sympathy with nature, its splendid description, delicacy of feeling, skill in arrangement, and varied majesty of verse. Thomson's *Seasons* is the chief of its English imitations, which include also Phillips' *Cyder* and Dyer's *Fleece*. About 29 V. began his greatest work, the *Æneis*, 'The Imperial Poem, and Mirror of the Glory of Rome.' He left it still unfinished at his death, when he instructed Varius and Tucca, his literary executors, to burn it; but by command of Augustus the whole was published intact. V. was all his life a student, and in his *Æneid*, which teems with exact descriptions of religious detail, and is embellished like *Paradise Lost* with great wealth of local allusions, he drew on all the vast storehouse of Greek literature and heroic legend. The story of Æneas and his Trojans wandering to the W. and 'founding the Roman race' was prepared by Stesichorus (600 B.C.) and Timæus of Tauromenium (262 B.C.), and was already incorporated in the *Annals* of the Pontiffs. It exactly suited V.'s purpose for a heroic poem on the origin of Rome and the glory of the Julian gens. Rome and Augustus are always before the poet of the *Æneid*. Anchises, in the shades, yields indeed to Greece the palm of art and science, but for Greek liberty and valour he has no praise, his climax is the grandeur of Rome, ''Tis thine, O Rome! to rule; this mission ne'er forego.' V. was unanimously accepted in his lifetime as the perfect exponent of the idea of Roman world-dominion. The fixed order of nature revealed in the *Georgics* has its counterpart in the *Æneid* in the coherent body of universal law that Fate impelled the inexorable *imperium* of Rome to stretch from the Euphrates to the Rhine. If the majestic simplicity of the *Georgics*, preaching the revival of early virtue and rural toil, first presented Italy as a living whole, it is in the *Æneid* that the imperial thought of the destiny of the eternal city, which has swayed Italian minds from Ennius to Mazzini, finds its supreme expression. 'The *Georgics* had been the psalm of Italy, the *Æneid* was the sacred book of the religion of Rome.' And though it is not true that 'V.'s eyes first saw the star of Bethlehem,' there is in V. an ever-recurring tone of mystic hope in a glorified future for humanity that has appealed to Christians of every age, from Augustine to Keble. 'It was given to V.,' said St. Beuve, 'at a decisive hour in history, to divine what the future would love,' and even 'in his single words and phrases, his pathetic half-lines,' Newman hears 'utterance, as the voice of Nature herself, to that pain and weariness, yet hope of better

things, which is the experience of her children in every time.' The reputation of V. was above Homer's for centuries. The early Christian writers, especially St. Augustine, are deeply imbued with his spirit, and to Dante V. was 'the master and guide from whom alone he derived the beauty of his style.' V.'s rank was never higher than in the period between Milton and Goethe. Bossuet knew him by heart. Burke had the *Æneid* always open by him. Immense also has been V.'s influence on education in ancient Rome, in the Middle Ages, in modern times. Few writers have been so often quoted, and if we forget Niebuhr's disparagement of 'the chastest poet, and royalest, that to the memory of man is known,' nineteen centuries join in the words of Macrobius, 'Such is the glory of Maro, that no man's praise can add to it, no man's blame diminish it.' The *editio princeps* of V. was published at Rome in 1469, since which date, says Heyne, no year has been without at least one edition. Servius' valuable commentary (A.D. 395) was first edited in 1471. Among the most important editions are De la Cerda (Madrid 1608-17); Nic. Heinsius (Amst. 1664); Burmann, with Heinsius' notes (Amst. 1746); Heyne (1767-88); Heyne-Wagner (1830-41). Among Virgilian scholars the greatest names are Burmann, Martin, Mittaire, Baskerville, Heyne, Wagner, Forbiger, Keightley, Conington, Gossrau, Ribbeck, Boissier, Kennedy, and Sellar. See the editions of Ribbeck (5 vols. 1859-68), Conington (3 vols. 1865-71), Ladewig (3 vols. 1870), Forbiger (4th ed. 1872), and Sellar's *Virgil* (Oxf. Clar. Press, 1877).

Virgil the Magician.—Just as the vulgar has ascribed to magic the forgotten origin of Stonehenge, so V.'s fame, outliving the poems that gave it birth, transformed the poet into a veritable Wizard of the South. That fame was firstly due to the veneration in which the *Æneid* was held by Pagan Rome as a faultless embodiment of the national faith and history, a veneration that found expression in the *Sortes Virgilianæ*, and next to Christians' interpretation of the Fourth Eclogue as a Messianic prophecy, which gave rise to countless allegorisings of the *Æneid's* self, and made Dante choose V. for his half-pagan, half-Christian guide. V., men said, had like the Magi beheld the Star, and from a magus to a magician the transition was easy. Thus myths grew up around the tomb at Naples, over which, according to the old Latin hymn, St. Paul had wept; and it is in Neapolitan folklore that Comparetti places the starting-point of V.'s magic fame, nearly all the earlier legends relating to talismans wrought by him for the good of Naples. John of Salisbury's *Polycraticon* (1156) speaks, it is true, merely of V.'s making a fly that destroyed all other flies, but a little later Konrad of Querfurt declares how he himself had seen the model of Naples enclosed by V. in a bottle, to guard the city as a Palladium from all its enemies, his statue of an archer whose arrow pointed at Vesuvius restrained eruptions, and similar marvels dear to the writer who in Southern Italy discovered Olympus, Parnassus, and Hippocrene. Further accretions—*e.g.*, of the brazen head, the magic garden, and the basket trick—often derived from Eastern sources, are found in *De Natura Rerum* of Neckam, Cœur-de-Lion's foster-brother, in Wolfram von Eschenbach's *Parcival* (1203-15), in Gervase of Tilbury's *Otia Imperialia* (*circa* 1211), in the *Image du Monde* (1245), a French encyclopædic poem, in the *Dolopathos* version of the *Seven Wise Masters* (q. v.), in the *Gesta Romanorum* (q. v.), and in a multitude of works by Italian, French, German, English, even Icelandic writers. With the revival of V.'s literary reputation the legend naturally waned, and its latest, scarce recognisable appearance, is in a Spanish romance of the middle of the 16th c. Paracelsus, indeed, alludes to it, and Evelyn saw at Paris a magic mirror ascribed to V., whose art is even to-day invoked in Italian love songs. See Zappert, *V.'s Fortleben im Mittelalter* (Vien. 1851); Genthe, *Leben und Fortleben des P. Virgilius Maro als Dichter und Zauberer* (Leip. 1857); and especially D. Comparetti, *Virgilio nel Medio Evo* (2 vols. Legh. 1872; Ger. trans. Leip. 1875), reviewed in the *Edinburgh* (July 1875).

Vir'gin Islands is the name given to an extensive group of small islands in the West Indies, lying between 18° 5' and 18° 50' N. lat., 64° 10' and 65° 40' W. long., exclusive of Santa Cruz, 50 miles to the S., which, though politically united with the V. I., is geographically distinct. The length of the entire group is about 100 miles, and its breadth 20 miles, but St. Thomas, the largest island, has an area of only 30 sq. miles, and most of them are exceedingly small. The character of the soil varies considerably in different islands, but in all it is fairly fertile; maize, sugar, indigo, and cotton being cultivated, while the castor-oil plant, the tamarind, the aloe, and the mahogany flourish wild in the woods. The surface is rocky and uneven, but the highest point, Sago Hill in Tortola, is only 1650 feet above the sea. Politically, the islands are divided between Great Britain, Denmark, and Spain; Tortola and Virgin Gorda or Spanish Town (said to be corrupted from Penniston) being the most important of those under British rule, St. Thomas, St. John, and Santa Cruz of those belonging to Denmark, while the largest of the Spanish Islands—Culebra—has an area of only 10 sq. miles, and a population of about 300. The British Islands are under the governor of St. Kitts, the Spanish are dependencies of Puerto Rico, and the Danish governor has his seat at Christianstadt, the capital of Santa Cruz. This island, 24 miles by 8 in size, is much more prosperous than any of the V. I. properly so called, possessing three good roads and two very respectable towns. The language generally spoken in it is English, which prevails over the whole group, with the exception of St. Thomas and John, which, having been originally colonised from Holland, retain the Dutch language. Pop. of the British V. I. (1871) 6651; of the Danish (1878) 37,600; of the Spanish, about 300. The V. I. were discovered by Columbus on his second voyage in 1494. In the 17th c. they became a favourite resort of buccaneers, after whose expulsion they changed hands frequently up to 1815, when their present political position was adjusted.

Vir'ginal, a keyed musical instrument which preceded the harpsichord. It derived its name probably from being used to accompany hymns to the Virgin, not from the fact of Queen Elizabeth's having been a skilful performer upon it, as has been erroneously supposed, the name being older than her time. The V. was in form like a desk of wood without legs, and was usually placed on a stand or table. It had a compass of from three to four octaves, one metal string being given to each of the notes, which were produced by the action of jacks of quill, whalebone, or leather.

Virgin'ia, one of the Middle Atlantic States of the American Union, bounded E. and S.E. by the Atlantic Ocean, S. by North Carolina and Tennesse, W. by Kentucky, and N.W. by West Virginia. Area, 38,348 sq. miles; pop. (1870) 1,225,163 (512,841 coloured). V. divides itself into the following six natural sections:—(1) *Tidewater V.*, the alluvial plain in the E. part of the State, lying along Chesapeake Bay, and extending W. as far as Richmond, nowhere more than 100 feet above the sea; (2) *Middle V.*, a triangular undulating plain, stretching W. from Richmond to the base of South-West Mountain, having an average elevation of 400 feet; (3) *Piedmont*, including both slopes of South-West Mountain and an undulating plain stretching to the base of the Blue Mountains; (4) *Blue Ridge*, a narrow belt parallel with the preceding, including both slopes of the Blue Ridge Mountains, the summits of which range from 2500 to 3000 feet in height; (5) *The Valley of V.*, a broad belt of undulating country from 1200 to 1600 feet above sea-level, of great fertility, and sheltered by the parallel chains of the Blue Mountains on the E., and the Kittatinny or Endless Mountains on the W.; (6) *Appalachia*, a region covered by the long parallel ridges of the Kittatinny Mountains and the intervening trough-like valleys. Of the rivers of V., the Kanawha or New River, empties into the Ohio directly; the Holston and Clinch, affluents of the Tennessee; and the Louisa, Russell, and Tug Fork affluents of the Big Sandy. Into Chesapeake Bay fall the Potomac (q. v.), the Rappahannock (q. v.), the Piankatank, the York (q. v.), and the James (q. v.). The principal geological formations in V. are the Pliocene, Miocene, and Eocene, the last irrupted occasionally by Triassic sandstone or Azoic rocks. Middle V. is Eozoic, while the Blue Ridge is a transition region. The rocks of the Valley are limestones, rich in mineral products. In the S.W. are thick seams of richly bituminous coal, covering 1000 sq. miles. Characteristic of V. are its numerous caves, rock-pillars, and natural bridges. Coal, gypsum, rock-salt, marble, lead, zinc, and plumbago are abundant, and gold is found in small quantities. Sulphurous and chalybeate mineral springs are numerous. The mean annual temperature varies from 60°-64° in the S.E., to 48°-52° in the Valley and Appalachia. In 1874 the chief crops were Indian corn, 19,082,000 bushels; wheat, 5,672,000; rye, 460,000; oats, 4,587,000; barley, 6300;

buckwheat, 40,000; potatoes, 1,068,000; tobacco, 35,000,000 lbs.; hay, 166,400 tons. In the same year the live stock was valued at $21,562,808, and consisted of 220,909 horses, mules, and asses, 567,289 cattle, 362,627 sheep and goats, and 571,779 swine. The principal manufactured articles are:—tobacco, flour-mill products, iron, lumber, cotton goods, and machinery. At the beginning of 1879 there were 1665 miles of completed railway within the State. The total imports for the year ending June 30, 1875, amounted to $487,082, and the exports to $8,189,327. The State capital is Richmond (q. v.). V. received its name from Queen Elizabeth in 1585, on the return of the expeditions despatched by Sir Walter Raleigh (q. v.). In 1606 South V. was granted to the 'London Company' by a patent, and on May 13, 1607, the first colony was planted and named James Town. It would have perished prematurely but for the courage and prudence of Captain John Smith. The colonists were on the point of abandoning the country in 1610, when Lord Delaware, who had been appointed governor, arrived with supplies and reinforcements. From this time V. began to flourish as the demand for its tobacco became greater in England. In 1624-25 the V. Company was dissolved and the colony reverted to the Crown. In 1619 V. obtained a colonial legislature, and in 1670 her aristocratic and conservative landowners limited the right of voting to freeholders and householders, while the Church of England was established by law, and persecuting laws passed against 'Nonconformists, Quakers, and Anabaptists.' Hostilities with the Indians and continual quarrels with the governors bring the history of V. down to 1754, when the war with the French commenced, in which Colonel Washington commanded the Virginian militia. V. opposed the levying of taxes by the mother country, and in 1765 adopted resolutions denying the right of England to impose them. In May 1776 she adopted a State Constitution, and entered with enthusiasm into the war. She led the way in summoning the National Convention which framed the Constitution of the United States, and kept her pre-eminence for thirty years. At the outbreak of the Civil War, by 88 to 55 votes at the State Convention of February 13, 1861, V. decided in favour of Secession. This was ratified in a plebiscite by a majority of 94,000 votes. The western counties opposed it, and accordingly the separate State of West V. was constituted in October of the same year. V. was occupied by hostile armies throughout the whole war.

Virgin'ia, West, one of the central states of the American Union, formed from Virginia in 1863, bounded S. and E. by Virginia, N. by Maryland and Pennsylvania, and on the W. separated from Ohio by the Ohio River, and from Kentucky by the Big Sandy River. Area, 23,000 sq. miles; pop. (1870) 442,014 (17,980 coloured). The most irregular in form of all the States, it includes a part of the Appalachian Valley, the western slope of the Appalachian range, and a portion of the upper valley of the Ohio. Its N.E. counties are drained by the Potomac, and its feeders, the Shenandoah and Opequan Creek. To the Potomac river system belongs a series of mountain-ridges sloping to the N.E., and separated by narrow and fertile valleys. W. of these extends in a narrow belt S.W. to the Big Sandy River the 'Mountain Region,' forming the western ridges of the Appalachian chain. Its highest summits are Panther Knob (4000 feet) and Haystack Knob (3800 feet). The rocks consist of parallel folds of sandstone resting on shales and limestones, through which streams, forcing their way to the Monongahela and Cheat rivers, have formed cañons, many of which are 1000 feet deep. Westwards to the Ohio extends a wider tract, called the 'Hilly Region,' with 20 peaks from 2200 to 3700 feet high. It slopes to the Ohio, and is drained by the Fishing Creek, Middle Island Creek, the Little and the Great Kanawha, Guyandotte, and the Big Sandy, with its affluent the Tug Fork. The chief geological formations are Lower Silurian, Devonian, and Carboniferous, irrupted here and there by Permian rocks. Of the great Appalachian coal-field, 16,000 sq. miles belong to the State. Rich iron ores are abundant, and salt is abundantly procured from springs of unusual purity. Petroleum is produced from over 400 springs, and many mineral springs exist, several thermal, the highest having a temperature of 107° F. In 1870 there were being worked within the State 185 mines and quarries, employing 1527 hands, and producing annually coal and iron ores to the value of $2,538,531. The soil is unusually fertile in the valleys and on the gentler mountain-slopes, and the climate is healthy, the mean temperature being 52° F. Over 9,000,000 acres of land are still in the original forest. The trees and wild animals found are those common to the Appalachians (q. v.). The chief crops in 1874 were Indian corn, 8,803,000 bushels; wheat, 3,268,000; rye, 268,000; oats, 1,684,000; barley, 50,000; buckwheat, 62,000; potatoes, 782,000; tobacco, 1,690,000 lbs.; hay, 167,880 tons. In the same year the live stock was valued at $18,948,283, and consisted of 116,877 horses, mules, and asses, 361,900 cattle (of which 124,300 were milch cows), 539,200 sheep, and 310,600 swine. The principal articles were iron and iron articles, flour-mill products, lumber, salt, leather, and glass. At the beginning of 1879 V. had 600½ miles of railway. The State formed the W. and N.W. portion of Virginia (q. v.) previous to the War of Secession. The capital is Wheeling (q. v.).
